# AIDS 2016

## 21ST INTERNATIONAL AIDS CONFERENCE

DURBAN, SOUTH AFRICA JULY 18–22, 2016

WWW.AIDS2016.ORG

## SCIENTIFIC PROGRAMME COMMITTEE

**Co-Chairs**
Kenneth Mayer, United States
Koleka Mlisana, South Africa
Stefan Baral, United States

**Members**

**Track A: Basic and Translational Research**
Souleymane Mboup, Senegal
Bruce Walker, United States

**Track B: Clinical Research**
Annette Sohn, Thailand
David Serwadda, Uganda

**Track C: Epidemiology and Prevention Research**
Helen Rees, South Africa
Sergii Dvoriak, Ukraine

**Track D: Social and Political Research, Law, Policy and** Human Rights
Mitchell Warren, United States
Safiatou Thiam, Senegal

**Track E: Implementation Research, Economics, Systems and** Synergies with other Health and Development Sectors
Wafaa El-Sadr, United States
Xavier Hospital, UNESCO

## SCIENTIFIC PROGRAMME TRACK COMMITTEES

### Track A: Basic and Translational Research

**Co-chairs**
Bruce Walker, United States
Souleymane Mboup, Senegal

**Committee members**
Dan Kuritzkes, United States
Frank Kirchhoff, Germany
Jessica Taaffe, United States
Luis Soto-Ramirez, Mexico
Nicole Frahm, United States
Sharon Lewin, Australia
Thumbi Ndung'u, South Africa
Wendy Burgers, South Africa

### Track B: Clinical Research

**Co-chairs**
Annette Sohn, Thailand
David Serwadda, Uganda

**Committee members**
Catherine Orrell, South Africa
Isabel Cassetti, Argentina
Jürgen Rockstroh, Germany
Meg Doherty, WHO
Nagalingeswaran Kumarasamy, India
Nittaya Phanuphak, Thailand
Papa Salif Sow, Senegal
Rohan Hazra, United States

### Track C: Epidemiology and Prevention Research

**Co-chairs**
Helen Rees, South Africa
Sergii Dvoriak, Ukraine

**Committee members**
Ada Adimora, United States
Faustine Ndugulile, South Africa
James McIntyre, South Africa
Morenike Ukpong, Nigeria
Patrick Ndase, Uganda
Patrick Sullivan, United States
Peter Godfrey-Faussett, UNAIDS
Vitaly Djuma, Estonia
Yiming Shao, China

### Track D: Social and Political Research, Law, Policy and Human Rights

**Co-chairs**
Mitchell Warren, United States
Safiatou Thiam, Senegal

**Committee members**
Anandi Yuvaraj, India
Eka Williams, South Africa
Fatou Maria Drame, Senegal
Francis Mangani, Zambia
Rosemary Mburu, Kenia
Sari Reisner, United States
Sinead Delany-Moretlwe, South Africa
Tilly Sellers, UNDP

### Track E: Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors

**Co-chairs**

Wafaa El-Sadr, United States
Xavier Hospital, UNESCO

**Committee members**
Catherine Hankins, The Netherlands
Dasha Matyushina-Ocheret, Lithuania
Harsha Thirumurthy, United States
Ivan Cruickshank, Jamaica
Janet Kayita, UNICEF
Judith Auerbach, United States
Mario Bronfman, Mexico
Nhlanhla Ndlovu, South Africa

# ABSTRACT MENTOR PROGRAMME

The Abstract Mentor Programme provides an opportunity for early-career investigators to receive feedback from more experienced researchers on their draft abstracts. The programme links mentees to mentors within the same track to maximize the use of the mentors' expertise. Participants are also given the chance to take part in an online e-course on conference abstract writing.

This year, 170 mentors reviewed 143 draft abstracts submitted by 110 researchers.
105 of them were submitted to AIDS 2016 and the following were selected:

- 1 Oral Abstract
- 1 Poster Discussion Session
- 30 Poster Exhibition

We would like to thank all volunteer abstract mentors, listed below, who supported early-career HIV researchers improve the quality of their abstracts.

Abdulkareem Jika Yusuf, Nigeria
Alexandra Martin-Onraet, France
Alfred Osoti, Kenya
Alice Armstrong, South Africa
Alicen Spaulding, United States
Allison Carter, Canada
Almoustapha Maiga, Mali
Amit Achhra, India
Amobi Onovo, Nigeria
Andrew Edmonds, United States
Andrew Etsetowaghan, Nigeria
Anil Pratap Singh, India
Anna Vinogradova, Russian Federation
Anna Grimsrud, Canada
Anne Gumbe, Kenya
Annie Phoebe Kalyanasundaram, India
Atheendar Venkataramani, United States
Axel Jeremias Schmidt, Germany
Barbara Burmen, Kenya
Bartholomew Ibeh, Nigeria
Bernadette Ngeno, Kenya
Bernardino Roca, Spain
Bo Hønge, Denmark
Brendan Maughan-Brown, South Africa
Brent Allan, Canada
Brooke Nichols, United States
Carol Metcalf, South Africa
Carolyn Audet, Canada
Catherine Egbe, Nigeria
Catherine Oldenburg, United States
Cecilia Moore, Australia
Chandrakant Lahariya, India
Charles Van Der Horst, United States
Chen Zhang, China
Cheryl Johnson, United States
Chloe Teasdale, United States
Christina Psaros, United States
Christine Kapira Chingondole, Malawi
Christine Mattson, United States
Clare Van Halsema, United Kingdom
Claudia Palladino, Italy
Collins Iwuji, United Kingdom
Corneli Amy, United States
Damilola (Lola) Walker, Nigeria
Darrin Adams, United States
Darshini Govindasamy, South Africa
David Lubogo, Uganda
Deborah Brickley, United States
Deborah Jones, United States
Denise Evans, South Africa
Diego Cecchini, Argentina
Dmitry Kireev, Russian Federation
Donn Colby, United States
Dorina Onoya, The Democratic Republic of the Congo
Ellen Koenig, United States
Ellen Tedaldi, United States
Emilie Venables, United Kingdom
Enric Pedrol, Spain
Eric Nagaonlé Some, Burkina Faso
Eric Tenkorang, Ghana
Ezequiel Cordova, Argentina
Fabiani Frantz, Brazil
Gabriela Carriquiry, Peru
Gabriela Patten, South Africa
Ganesh Shanmugasundaram Anusuya, India
Genaro Castro-Vazquez, Mexico
Geofrey Musinguzi, Uganda
Giulia Marchetti, Italy
Guy Harling, United Kingdom
Gylce Cruz, Brazil
Halima Dawood, South Africa
Hong Van Tieu, United States
Idun Test, Norway
Isabel Sada, Mexico
J.Anitha Menon, India
Jamila K. Stockman, United States
Janan Janan Dietrich, South Africa
Jean Joel Bigna Rim, Cameroon
Jean-Pierre Routy, France
Jeffrey Lazarus, Czech Republic
Jessica Magidson, United States
Jo Vearey, United Kingdom
Joyce Namale Matovu, Uganda
Karsten Lunze, Germany
Kathleen (Kate) Powis, United States
Kennedy Nkhoma, Malawi
Kenneth Ngure, Kenya
Keshab Deuba, Nepal
Krishna Poudel, Nepal
Letitia Rambally - Greener, South Africa
Linnet Masese, Kenya
Lisa Langhaug, United States
Lorna Leal, Mexico
Luis F M Brigido Luis Brigido, Brazil
Macarena C García, United States
Makandwe Nyirenda, Zambia
Mansour Farahani, United States
Marcel Yotebieng, Cameroon
Maria Eugenia Socias, Argentina
Maria L Alcaide, United States
Marlene Bras, France
Martin Herbas Ekat, Congo
Martin Holt, United Kingdom
Martin Muhire, Uganda
Maryam Shahmanesh, United Kingdom
Melanie Plazy, France
Melissa Marzán-Rodríguez, Puerto Rico
Mia Liisa Van Der Kop, Canada
Milosz Parczewski Parczewski, Poland
Moses P. Adoga, Nigeria
Nazisa Hejazi, Islamic Republic Of Iran
Nicola Gianotti, Italy
Nompumelelo Zungu, South Africa
Norliana Khairuddin, Malaysia
Okechukwu Kalu Iro, Nigeria
Oliver Laeyendecker, United States
Onyemaechi Okpara Azu, Nigeria
Pablo Belaunzarán-Zamudio, Mexico
Pablo Rojo, Spain
Paradise Madlala, South Africa
Pascal Bessong, Cameroon
Patricia Pérez-Matute, Spain
Paul Kawale, Malawi
Petros Isaakidis, Greece
Pinar Oktem, Turkey
R. Keith Reeves, United States
Rebecca Tadokera, Zimbabwe
Renee Heffron, United States
Reshu Saxena, India
Reuben Musarandega, Zimbabwe
Richard Lessells, United Kingdom
Robert Freeman, United States
Roberto Santos, United States
Ross Greener, South Africa
Ruth Goodall, United Kingdom
Sabine Hermans, Netherlands
Sai Ko Ko Zaw, Myanmar
Sarah Beckham, United States
Sasisopin Kiertiburanakul, Thailand
Saul Cobbing, South Africa
Sergio Rueda, Venezuela
Siddharudha Shivalli, India
Simbarashe Takuva, South Africa
Srikanth Kondreddy, India
Stephanie Topp, Australia
Steve Innes, South Africa
Su-Anne Charlery White, Saint Lucia
Sue-Ann Meehan, South Africa
Sundhiya Mandalia, United Kingdom
Surya Rao Kutikuppala, India
Susan Aitken, South Africa
Susan Herrmann, Australia
Susannah Allison, United States
Tanushree Banerjee, India
Tassos Kyriakides, United States
Tesmerelna Atsbeha, United States
Thierry Malebe, Zambia
Tinashe Mudzviti, Zimbabwe
Valeria Ghisetti, Italy
Vaneet Sharma, India
Veronica Njie-Carr, United States
Verusia Chetty, South Africa
Vicente Estrada, Spain
Vicki Tepper, United States
Weiming Tang, China
William Christopher Mathews, United States
William Massavon, Ghana
Wondu Teshome Amenu, Ethiopia
Wondwossen Terefe Lerebo, Ethiopia
Ximena Salazar, Peru

# INTERNATIONAL ABSTRACT REVIEW COMMITTEE

The The 21st International AIDS Conference received more than 7,100 abstract submissions, which went through a blind, peer-reviewed process carried out by an international panel of reviewers who play a critical role in designing a strong scientific programme.

Around 1,000 specialists from around the world volunteered their time and expertise to serve as peer reviewers, helping to ensure that the abstracts presented were selected on the basis of rigorous review and were of the highest scientific quality.

We extend our special thanks to the large pool of abstract reviewers for the time they dedicated to the success of the conference:

Salim Abdool Karim, South Africa
Abu Abdul-Quader, United States
Elaine Abrams, United States
Lisa Abuogi, United States
Jeffry Acaba, Thailand
Sylvia Adebajo, Nigeria
Adaora Adimora, United States
Carlos Adon, Dominican Republic
Kawango Agot, Kenya
Abhina Aher, India
Ali Ahmad, Canada
Atsushi Ajisawa, Japan
Ajaz Akhtar, Pakistan
Jose Alcami, Spain
Anna Aldovini, United States
Grace Aldrovandi, United States
Todd Allen, United States
Dan Allman, Canada
Olakunle Alonge, United States
Dennis Altman, Australia
Ugo Amanyeiwe, United States
Atul Ambekar, India
K. Rivet Amico, United States
Janaki Amin, Australia
Frank Michael Amort, Austria
Jintanat Ananworanich, Thailand
Erica Andersen-Nissen, South Africa
Terje Anderson, United States
Jonathan Angel, Canada
Cristian Apetrei, United States
Victor Appay, France
Chris Archibald, Canada
Roberto Arduino, United States
Gabriele Arendt, Germany
Radka Argirova, Bulgaria
Emily Arnold, United States
Jose Arribas, Spain
Judith Auerbach, United States
Santiago Avila-Rios, Mexico
Nwe Nwe Aye, Myanmar
Helen Ayles, Zambia
Ahidjo Ayouba, France
Tasnim Azim, Bangladesh
Alain Azondekon, Benin
Iskandar Azwa, Malaysia
David Back, United Kingdom
Abdallah Badahdah, United States
Andrew Badley, United States
Jared Baeten, United States
Rachel baggaley, Switzerland
Prince Bahati, Kenya
Andrew Ball, Switzerland
Stephen Banspach, United States
Stefan Baral, Canada
Jason Barbour, United States
Francis Barin, France
Nielan Barnes, United States
Deborah Baron, South Africa
Dan Barouch, United States
Françoise Barré-Sinoussi, France
Rolando Barrios, Canada
John A. Bartlett, United States
Emily Bass, United States
Ingrid Bassett, United States
Francisco Bastos, Brazil
Manuel Battegay, Switzerland
Sally Beadle, Australia
Belinda Beauchamp, Puerto Rico
Eduard Beck, Canada
Richard Bedell, Canada
Josip Begovac, Croatia
Homira Behbahani, Sweden
Georg Behrens, Germany
Laurent Belec, France
Stephen Bell, Australia
Jorge Benetucci, Argentina
Thomas Benfield, Denmark
Eddas Bennett, United States
Constance Benson, United States
Philip Berger, Canada
Colm Bergin, Ireland
Ben Berkhout, Netherlands
Nicole Bernard, Canada
Brookie M. Best, United States
Daniela Bezemer, Netherlands
Sanjay Bhagani, United Kingdom
Paurvi Bhatt, United States
Adisak Bhumiratana, Thailand
Gunnel Biberfeld, Sweden
Caroline Bishop, United States
Julià Blanco, Spain
Kim Blankenship, United States
Joel Blankson, United States
Emily Bobrow, United States
Naomi Bock, United States
Christoph Boesecke, Germany
David Boettiger, Australia
Vicente Boix, Spain
Rosa Bologna, Argentina
Morgane Bomsel, France
Stefano Bonora, Italy
Peter Borges, India
Alberto Bosque, United States
Anan Bouapha, Lao People's Democratic Republic
Adam Bourne, United Kingdom
Maria Belen Bouzas, Argentina
Mark Boyd, Australia
Ivana Bozicevic, Croatia
Patricia Bracamonte, Peru
Paula Braitstein, Kenya
Sara Brewer, United States
Mark Brockman, Canada
Norbert Brockmeyer, Germany
Mario Bronfman, Mexico
John T Brooks, United States
Tim Brown, United States
Todd Brown, United States
Zabrina Brumme, Canada
Julie Bruneau, Canada
Cassia Maria Buchalla, Brazil
Michael Bukrinsky, United States
Elizabeth Bukusi, Kenya
Torsak Bunupuradah, Thailand
Supranee Buranapraditkun, Thailand
Harold Burger, United States
Wendy Burgers, South Africa
Naomi Burke Shyne, United Kingdom
Ines Bustamante, Peru
Jenny Butler, Turkey
Maria Buzon, Spain
Maria Lorena Cabrera-Ruiz, Mexico
Pedro Cahn, Argentina
Liliana Calanni, Argentina
Alexandra Calmy, Switzerland
Bilali Camara, Nigeria
Cristina Camara, Brazil
Saulius Caplinskas, Lithuania
Irma Caplinskiene, Lithuania
Alex Carballo-Dieguez, United States
Adam Carrico, United States
Patrizia Carrieri, France
José L. Casado, Spain
Isabel Cassetti, Argentina
Fabian Cataldo, United Kingdom
Marta Catalfamo, United States
Roberto Cauda, Italy
Luca Ceccherini-Nelli, Italy
Veronica Cenac, Canada
Robert Center, Australia
Carina Cesar, Argentina
Joana Chakraborty, United States
Rana Chakraborty, United States
Thep Chalermchai, Thailand
Dick Chamla, United States
Larry Chang, United States
Jenifer Chapman, Mozambique
Jean-Marc Chapplain, France
Charlotte Charpentier, France
Manhattan Charurat, United States
Charles Chasela, South Africa
Robert Chen, United States
Peter Cheung, Canada
Remi Cheynier, France
Benjamin Chi, United States
Jeremiah Chikovore, South Africa
Frank Chimbwandira, Malawi
David Chipanta, Switzerland
Kyung-Hee Choi, United States
Nicolas Chomont, Canada
Denis Chopera, South Africa
Celia Christie, Jamaica
Sandra Ka Hon Chu, Canada
Gavin Churchyard, South Africa
Jesse Clark, United States
Michaela Clayton, Namibia
Farley Cleghorn, United States
Mario Clerici, Italy
Bonaventura Clotet, Spain
Nathan Clumeck, Belgium

Lucie Cluver, South Africa
Alan Cochrane, Canada
David Coetzee, South Africa
Patrick Coffie, Cote D'Ivoire
Joseph Cofrancesco, United States
Calvin Cohen, United States
Craig Cohen, United States
Desmond Cohen, United Kingdom
Myron Cohen, United States
Susan E. Cohn, United States
Donn Colby, Thailand
Robert Colebunders, Belgium
Ann Collier, United States

# TABLE OF CONTENTS

## Tuesday 19 July

### Tuesday Oral Abstract Sessions

| | | |
|---|---|---|
| TUAA01 | Drivers of HIV Progression | 17 |
| TUAB01 | Long-term Treatment Success for Adolescents and Young Adults | 18 |
| TUAB02 | Clubs, Cash and Caregivers: Impact on Adherence and Retention | 21 |
| TUAC01 | PrEP: New Drugs, New Questions | 23 |
| TUAC02 | Can Epidemiology Lead to Action: Who, Where, When? | 24 |
| TUAD01 | Pathways: Moving from Structural Risks to Responses | 26 |
| TUAD02 | Reality Check: The Intersections of HIV, Violence and Trauma | 28 |
| TUAD03 | Sex, Babies and Life: Effective Reproductive Health Programmes | 30 |
| TUAD04 | Shame-Less: Stigma Interventions That Work | 32 |
| TUAE01 | Healthy Mothers, Healthy Babies: The Path to eMTCT | 34 |
| TUAX01 | Late Breaker Session | 36 |

### Tuesday Oral Poster Discussions

| | | |
|---|---|---|
| TUPDA01 | HIV Transmission and Pathogenesis | 39 |
| TUPDB01 | HIV Drug Resistance: Is it Time to Worry? | 41 |
| TUPDC01 | Measuring Progress Towards 90-90-90 | 43 |
| TUPDD01 | Human Rights, Wrongs and Realities: Translating Frameworks into Actions | 45 |
| TUPDD02 | WhatsUp: Mobile Technologies, Multimedia and Mass Communications | 47 |
| TUPDD03 | The New Normal: Sexual Identity, Relationships and Norms | 49 |
| TUPDE01 | Quality Improvement: Aim High | 51 |

### Tuesday Poster Exhibition

**Track A >** **Track A - Basic and Translational Research**

| | | |
|---|---|---|
| PEA001-A002 | Mechanisms of activation / inflammation and impact on pathogenesis | 54 |
| PEA003-A006 | Mechanisms of T cell depletion and reconstitution | 54 |
| PEA007 | Correlates and biomarkers of clinical progression of HIV infection | 56 |
| PEA008 | Viral determinants of pathogenesis | 56 |
| PEA009-A010 | Central Nervous System | 56 |
| PEA011-A013 | HIV-1 controllers (including post-treatment controllers) | 57 |
| PEA014 | Host cellular factors and latency | 58 |
| PEA015-A016 | Host genetics of HIV susceptibility and disease progression | 58 |
| PEA017-A019 | Mucosal transmission | 59 |
| PEA020 | Vertical transmission | 60 |
| PEA021-A023 | Acute and early infection | 60 |
| PEA024 | Preclinical drug development | 61 |
| PEA025 | Preclinical prophylactic drug development | 61 |
| PEA026 | Mycobacteria and tuberculosis | 62 |
| PEA027 | Other pathogens (including HPV, syphilis and Cryptococcus) | 62 |
| PEA028-A029 | Animal models of transmission, disease resistance and progression | 62 |
| PEA030 | Novel animal/virus models for vaccine, cure research, and inhibitor development | 63 |

**Track B >** **Track B - Clinical Research**

| | | |
|---|---|---|
| PEB031-B032 | Disease burden: morbidity / mortality / life expectancy | 63 |
| PEB033-B039 | Cohort studies | 64 |
| PEB040-B045 | Linkage to care | 67 |
| PEB046-B066 | Retention in care | 70 |
| PEB067 | Indicators of quality of care | 76 |
| PEB068-B077 | Across the cascade from HIV testing to care and treatment to retention | 77 |
| PEB078-B083 | Diagnosis of HIV disease in infants, children, and adolescents | 80 |
| PEB084-B085 | Pharmacokinetics / pharmacodynamics / pharmacogenomics in infants, children, and adolescents | 82 |
| PEB086-B087 | Clinical trials and antiretroviral therapy in infants, children, and adolescents | 83 |
| PEB088-B097 | Adherence in children and adolescents | 83 |
| PEB098-B101 | Complications of HIV and their therapy in children and adolescents | 88 |
| PEB102-B103 | Comorbidities in children and adolescents (including non-communicable diseases) | 89 |
| PEB104-B105 | Opportunistic infections in infants, children, and adolescents | 90 |
| PEB106-B108 | HIV-exposed uninfected children (including effects of ART exposure during pregnancy) | 91 |
| PEB109-B112 | ARV management strategies: children and adolescents cohort studies | 92 |
| PEB113-B115 | Behavioural health outcomes in children and adolescents (including sexual risks, substance use) | 94 |
| PEB116-B123 | Mental health and neuro-cognition in children and adolescents | 95 |
| PEB124-B126 | Retention in care of adolescents | 98 |
| PEB127 | Transition into adult care | 99 |

**Track C >** **Track C - Epidemiology and Prevention Research**

| | | |
|---|---|---|
| PEC128-C134 | Trends in morbidity and mortality | 99 |
| PEC135-C138 | Measurement and modelling of the HIV epidemics | 102 |
| PEC139-C144 | Risk factors for acquisition of HIV | 103 |
| PEC145-C146 | Risk factors for infectivity, progression and transmission of HIV | 106 |
| PEC147-C152 | Epidemiology of HIV in the general population | 106 |
| PEC153-C157 | Epidemiology of HIV in children | 109 |
| PEC158-C168 | Epidemiology of HIV in youth and adolescents | 111 |
| PEC169-C170 | Epidemiology of HIV in the elderly | 115 |
| PEC171-C173 | Epidemiology of HIV in people who use drugs | 115 |
| PEC174-C176 | Epidemiology of HIV in male, female and transgender sex workers | 116 |
| PEC177-C190 | Epidemiology of HIV in MSM | 117 |
| PEC191-C193 | Epidemiology of HIV in serodiscordant couples | 122 |
| PEC194-C197 | Epidemiology of HIV in migrants | 123 |

PEC198-C199 Epidemiology of HIV in transgender persons 125
PEC200-C201 Epidemiology of HIV in other populations 125
PEC202-C203 Epidemiology of TB and HIV co-infection 126
PEC204-C211 Epidemiology of sexually transmitted infections (STI) and HIV co-infection 127
PEC212 Epidemiology of viral hepatitis and HIV co-infection 129
PEC213-C215 Epidemiology of other diseases and HIV co-infection 130
PEC216-C219 Molecular epidemiology 131
PEC220-C223 Geographical information systems and HIV 132
PEC224-C234 Studies of risk behaviours and their implications for prevention 134
PEC235 Research designs in epidemiology 137
PEC236 Ethical and human rights issues in prevention research 137
PEC237-C238 Estimation of the size of HIV-infected and key populations 138
PEC239-C240 Surveillance of hepatitis C (HCV) and HIV co-infection 139
PEC241 Surveillance of TB and HIV co-infection 139
PEC242 Assessment of population viral load in epidemiology studies 140
PEC243-C244 Assessing impact/cost-effectiveness of structural interventions 140
PEC245-C248 Gender sensitization, empowerment and violence reduction 141
PEC249 Collectivization, mobilization, stigma reduction programmes 142

## Track D > Track D - Social and Political Research, Law, Policy and Human Rights

PED250-D260 Positive health, dignity, psychological well-being and mental health 142
PED261-D265 Adaptation to living with HIV for individuals, families and communities 146
PED266-D275 Experiences and impacts of antiretroviral therapy 147
PED276-D295 Growing up with HIV: specific needs and interventions for children, adolescents and youth 150
PED296-D308 Ageing with HIV: evolving and additional needs and responses 157
PED309-D312 Prevention interventions and their effects on the lives and relationships of people living with HIV 160
PED313-D321 Sexual and reproductive health, fertility, family planning and abortion 161
PED322 HIV and the workplace: discrimination, unemployment, return to work and rehabilitation 164
PED323-D324 Living with HIV and co-infections and/or co-morbidities 165
PED325-D338 Conceptualizing social and structural factors and their impacts 165
PED339-D344 Socio-economic differences: poverty, wealth and income inequalities 169
PED345-D349 Dynamics of social status and power: gender, age, ethnicity and disability 171
PED350 Economic transitions and social and cultural change 173
PED351 Economic and social dynamics and impacts of intergenerational and/or transactional sex 173
PED352-D361 Violence and conflict: political, social, structural, interpersonal and family-based 173
PED362-D367 Sexuality and gender-based violence and exploitation, including in conflict settings 177
PED368 Media, cultural and religious representations of HIV and AIDS 178
PED369-D379 Experiences and impacts of HIV-related stigma 179
PED380-D407 Stigma and discrimination in specific settings, including family, community, work place, education and healthcare settings 182
PED408 Representations of stigma: social attitudes, media and public debate 191
PED409-D419 Legal protection of people living with HIV and key populations 191
PED420-D427 Social and political advocacy and mobilization 194
PED428-D430 Couples- or family-centred approaches 197
PED431 Comprehensive services for the prevention of vertical transmission, including early childhood development, child care and nutrition support 198
PED432-D434 Incentives, micro-finance and other economic support 198
PED435-D436 Safe housing, social protection and other care and support for those affected by HIV 199
PED437-D438 Development and poverty alleviation 200
PED439-D445 Tackling stigma and stigma reduction interventions 200
PED446-D448 Traditional and complementary approaches 203
PED637 Adherence to antiretroviral therapy, including when used as prevention or for chemoprophylaxis 264
PED638 Experiences and impacts of HIV-related stigma 264

## Track E > Track E - Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors

PEE449-E462 Voluntary counselling and testing programmes and other approaches to HIV testing such as community-based testing and self-testing 203
PEE463-E465 Gender-responsive HIV programming 208
PEE466-E472 Modelling, development, implementation, and evaluation of HIV-related policies 209
PEE473 Innovations in testing and laboratory support (including point-of-care diagnostics) 211
PEE474-E476 Modelling, development, implementation, and evaluation of HIV-related policies 211
PEE477-E482 Procurement and supply chain management 212
PEE483-E493 Strategies to improve uptake and outcomes in HIV-infected children and adolescents 214
PEE494-E499 Partnerships involving donors, NGOs, and government 218
PEE500-E502 Effects of public-private partnerships, including workplace programmes and policies 220
PEE503-E506 Working with community-led organizations, including of key populations, faith-based groups, and traditional healer organizations, and with community leaders 221
PEE507-E516 Sexual and reproductive health and HIV services: delivery models and costs 222
PEE517-E520 Analyses of changes in policy and practice 225
PEE521-E523 Impact of HIV funding/programming on reproductive health and other disease outcomes 227
PEE524-E527 Effects of HIV programming (prevention and treatment) on development outcomes (e.g., schooling) 228
PEE528 Micro-economic and macro-economic impacts of HIV programmes and policies 229
PEE529-E547 Interventions to increase demand, uptake and retention of vulnerable and key populations for HIV prevention and care programmes 229
PEE548-E552 Funding for programmes for key populations 235

| | | |
|---|---|---|
| PEE553-E561 | Integration of HIV and sexual and reproductive health for key populations | 237 |
| PEE562-E578 | Prevention and treatment programmes for and with adolescents and young people, including those from key populations | 240 |
| PEE579-E580 | Impact of donor agencies and policies on national responses | 245 |
| PEE581-E591 | Sustainability of financing and programmes of national AIDS programmes and responses | 246 |
| PEE592-E593 | National financing initiatives | 249 |
| PEE594 | Transitional financing | 250 |
| PEE595-E596 | International assistance, frameworks and funding mechanisms | 250 |
| PEE597 | Effect of health insurance schemes and other support models on access, adherence, and outcomes | 251 |
| PEE598 | Effects of financial crises | 251 |
| PEE599-E623 | Economic evaluation of prevention, treatment, and/or care programmes | 251 |
| PEE624-E628 | Pharmaco-economics | 259 |
| PEE629 | Managing HIV supply chain challenges with limited resources | 261 |
| PEE630-E631 | Key populations in humanitarian settings and fragile contexts | 261 |
| PEE632-E633 | Lessons learned for HIV in the context of the millennium development goals (MDGs) | 262 |
| PEE634 | Challenges and opportunities for HIV in the context of the sustainable development goals (SDGs) | 263 |
| PEE635 | Scale up of paediatric diagnosis | 263 |
| PEE636 | Scale-up of HIV self-testing | 263 |

# Wednesday 20 July

## Wednesday Oral Abstract Sessions

| | | |
|---|---|---|
| WEAA01 | Acute HIV Infection: The Battle Begins | 265 |
| WEAB01 | Supporting Three Generations of Healthy Mothers and Healthy Babies | 267 |
| WEAB02 | Taking TB from Testing to Treatment | 269 |
| WEAB03 | Bad Bugs, Better Drugs: Advances in Hepatitis and HIV Co-Infection Treatment | 271 |
| WEAC01 | Making PrEP Real for Those Who Need It Most: Optimization Strategies | 273 |
| WEAC02 | Trans-forming HIV Prevention and Care Talk | 275 |
| WEAC03 | Adolescent Affairs | 277 |
| WEAC04 | Alcohol, Substance Use and HIV | 279 |
| WEAD01 | It's All In the Family | 280 |
| WEAD02 | Sex through the Ages | 282 |
| WEAD03 | Pulling the Levers: Policy, Advocacy Approaches to Influence | 284 |
| WEAE01 | Innovations in HIV Testing: the First 90 | 286 |
| WEAE02 | Target 90-90-90: The Ups and the Downs | 288 |
| WEAE03 | Going Viral for Viral Load Implementation | 290 |

## Wednesday Oral Poster Discussions

| | | |
|---|---|---|
| WEPDA01 | Intrinsic and Adaptive Immunity | 293 |
| WEPDB01 | Living with HIV: Long-Term Effects | 294 |
| WEPDC01 | Circumcision: Where to, How to, Who to? | 296 |
| WEPDC02 | Prevention for Women: The Need for Multidisciplinary Approaches | 298 |
| WEPDD01 | Translating Tradition in the AIDS Response | 300 |
| WEPDE01 | Filling the Gaps in PMTCT/B+ Programmes | 302 |
| WEPDE02 | It Takes a Community: Leadership, Engagement and Innovation | 304 |

## Wednesday Poster Exhibition

### Track A > Track A - Basic and Translational Research

| | | |
|---|---|---|
| PEA001-A004 | Viral diversity, phylogenetics and phylodynamics | 307 |
| PEA005-A006 | Viral dynamics and fitness | 308 |
| PEA007 | HIV-1 super-infection/inter/intra subtype co-infection | 308 |
| PEA008-A009 | Intrinsic cellular defences and restriction factors | 309 |
| PEA010 | Viral assembly and maturation | 309 |
| PEA011-A012 | Transcriptional and gene expression regulation (including regulatory genes) | 310 |
| PEA013-A015 | Viral replication (including necessary cellular elements) | 310 |
| PEA016 | Viral mechanisms of HIV/SIV persistence and latency | 311 |
| PEA017-A018 | Cellular and tissue reservoirs of HIV/SIV | 312 |
| PEA019 | Measurement of HIV/SIV reservoirs | 312 |
| PEA020-A026 | Targeting HIV persistence during ART (cure strategies) | 313 |
| PEA027-A028 | Novel assays of HIV infection | 315 |

### Track B > Track B - Clinical Research

| | | |
|---|---|---|
| PEB029 | Sex-based differences in HIV | 316 |
| PEB030-B031 | Diagnostics of co-infections (including syphilis, TB, Cryptococcus, hepatitis B, C and other) | 316 |
| PEB032-B037 | Opportunistic infections (excluding TB) | 317 |
| PEB038-B052 | Tuberculosis and other mycobacteria | 319 |
| PEB053 | Other bacterial infections and parasitic infections (including malaria) | 324 |
| PEB055-B058 | Hepatitis (excluding hepatitis C) | 324 |
| PEB059-B068 | Hepatitis C | 325 |
| PEB069-B070 | Human papillomavirus | 329 |
| PEB071-B072 | Other sexually transmitted infections | 330 |
| PEB073-B077 | HIV-associated neurocognitive disorder (HAND) | 330 |
| PEB078-B079 | Neurologic disorders (excluding HAND) | 332 |
| PEB080-B083 | Depression and other psychiatric manifestations | 333 |
| PEB084-B086 | Malignancies (including Kaposi sarcoma, lymphoma, and non-AIDS malignancies) | 334 |
| PEB087 | Fat accumulation and lipodystrophy | 335 |
| PEB088 | Cardiovascular disease | 335 |
| PEB089-B091 | Bone disease (including issues related to vitamin D) | 336 |
| PEB092-B093 | Renal disease | 337 |
| PEB094-B095 | Endocrine and metabolic issues (including diabetes, hyperlipidemia) | 338 |
| PEB096-B100 | Hepatic complications | 339 |
| PEB101-B103 | Ageing in persons with HIV (including frailty) | 340 |
| PEB104 | Immune reconstitution disorders / immune reconstitution inflammatory syndrome (IRIS) | 341 |
| PEB105-B106 | Other adverse reactions and complications of ART | 342 |
| PEB107-B111 | Other non-communicable diseases (including screening) | 342 |

PEB112 Pharmacokinetics and outcomes of ART in women during and after pregnancy 345
PEB113-B119 Other issues related to pregnancy 345
PEB120 PrEP for conception and other approaches for the serodiscordant couple to achieve conception 347
PEB121-B123 Issues related to hormonal and non-hormonal contraception 348
PEB125-B128 Other sex-specific issues 349

## Track C > Track C - Epidemiology and Prevention Research

PEC129-C130 Capacity building for HIV prevention research 350
PEC131 Community involvement in biomedical prevention 351

## Thursday Poster Exhibition

**Track A >** **Track A - Basic and Translational Research**

| | | |
|---|---|---|
| THPEA001-A004 | NK cells and dendritic cells | 557 |
| THPEA005 | Monocytes and macrophages | 558 |
| THPEA006 | Other innate immune responses | 558 |

THPEA007-A008 Antibody diversity and function 559
THPEA009 B cells and alterations in subsets 559
THPEA010-A013 T-cell immune responses (CD4 and CD8) 560
THPEA014 Mucosal immunity 561
THPEA015 Virus escape from adaptive immunity 561
THPEA016 Mechanisms underlying immune reconstitution inflammatory syndrome (IRIS) 562
THPEA017-A022 Targeting and eradication of reservoirs 562
THPEA023-A024 Systems biology approaches to HIV infection 564
THPEA025 Novel approaches in Immunotherapeutics (including bnAbs and anti-inflammatory mediators 564
THPEA026-A027 B cell-based vaccines 565
THPEA028 Novel vectors and strategies 565
THPEA029 Therapeutic vaccines 566
THPEA030 Novel assays of immune responses 566

## Track B > Track B - Clinical Research

THPEB031-B035 Acute and early infection 566
THPEB036-B042 HIV diagnostic testing (including new algorithms, rapid/point of care testing, and strategies for expanding/improving testing) 568
THPEB043-B045 CD4 measurement (including point of care diagnostics) 571
THPEB046 HIV RNA and HIV DNA assays (including point of care platforms) 572
THPEB047-B050 Drug resistance testing 572
THPEB051-B052 Clinical trials: phase I/II 574
THPEB053 Clinical trials: phase III 574
THPEB054 Clinical trials: post-licensing 575
THPEB055-B057 Timing of therapy initiation 575
THPEB058 First-line therapy 576
THPEB059-B060 Second-line therapy 576
THPEB061 Therapy in highly treatment-experienced persons 577
THPEB062-B063 Simplification (with one- or two-agent regimens) and switch studies 577
THPEB064 Pharmacology / pharmacokinetics / pharmacogenomics / role of therapeutic drug monitoring 578
THPEB065-B069 Antiretroviral drug resistance 578
THPEB070-B075 Adherence 580
THPEB076-B077 Ethical issues in clinical trials and treatment strategies 582
THPEB078-B082 Complementary and traditional medicines 583
THPEB083 Clinical approaches to drug and alcohol dependence treatment: 584
THPEB084 Nutrition and HIV 585
THPEB085 Streamlining ART initiation 585
THPEB086 Adherence among high CD4 persons 585
THPEB087-B091 Clinical issues in men who have sex with men 586
THPEB092-B094 Clinical issues in people who use drugs 587
THPEB095-B096 Clinical issues in transgender populations (including ART-hormone interaction) 589
THPEB097 Clinical issues in other key populations 589

## Track C > Track C - Epidemiology and Prevention Research

THPEC098-C099 Coverage of prevention services among key populations 589
THPEC100-C103 Prevention for vertical transmission 590
THPEC104-C106 Prevention for the general population 591
THPEC107-C132 Prevention for youth and adolescents 592
THPEC133-C148 Prevention for people who use drugs, including harm reduction 600
THPEC149-C158 Prevention for male, female and transgender sex workers 605
THPEC159-C185 Prevention for MSM 607
THPEC186-C188 Prevention for transgender persons 616
THPEC189-C193 Prevention for migrants, mobile and displaced populations 617
THPEC194-C199 Prevention for HIV serodiscordant couples 618
THPEC200-C204 Prevention for other vulnerable populations 620
THPEC205-C206 Population-based intervention studies 622
THPEC207-C225 Male circumcision 623
THPEC226-C227 Strategies for identifying key populations 629
THPEC228-C232 Combination prevention approaches (including interventions on gender-based violence, cash transfers and poverty) 629
THPEC233-C241 Reducing pre-partum and intra-partum transmission to infants 631
THPEC242-C246 Reducing post-partum transmission in infants 634
THPEC247-C249 Strategies to increase HIV testing in pregnant women and their partners 636
THPEC250-C257 Increasing coverage and quality of prevention of vertical transmission programmes 637
THPEC258-C260 Prevention of vertical transmission services for marginalized groups 640
THPEC261-C263 Integration of family planning and HIV services 641

## Track D > Track D - Social and Political Research, Law, Policy and Human Rights

THPED264-D274 Men who have sex with men 642
THPED275-D286 Transgender people 645
THPED287-D296 Female, male and transgender sex workers 649
THPED297-D301 People who use drugs, including injecting drug use 651
THPED302-D304 Indigenous people 653
THPED305-D313 Incarcerated people 654
THPED314-D320 Mobile, migrant and displaced population groups 657
THPED321 People with disabilities 659
THPED322-D331 Other vulnerable social groups, including in specific contexts 659
THPED332-D339 Adolescents and young people and sexuality and relationships 662
THPED340-D344 Same-sex-attracted, bisexual and queer people, including young people 665
THPED345-D353 Gender issues and gendered relationships 666
THPED354 Femininity, masculinity and transgender issues 669
THPED355-D364 Experiences and needs from the perspective of sex workers 669
THPED365 Owners, managers and management of sexual services and establishments 672
THPED366 Clients of sex workers: expectations and demands 672
THPED367-D377 Violence, wellbeing and sex work 673
THPED378-D379 Social networks and associations of sex workers 676
THPED380-D382 Specific practices, impacts and responses for distinct substances and modes of administration (including alcohol use, injecting drug use and non-injecting drug use) 677
THPED383-D386 Interplay between drug use and sexual transmission 678
THPED387 Social networks and associations of drug users 679
THPED388-D395 Intersecting stigmas and marginalized identities 679

| | | |
|---|---|---|
| THPED396 | Racism and other forms of ethnicity-based social exclusion | 682 |
| THPED397-D404 | Experiences and impacts of homophobia and transphobia | 682 |
| THPED405-D418 | Stigma and discrimination regarding people who use/inject drugs, sex workers, sexual minorities and other social groups affected by HIV | 685 |
| THPED419-D436 | Punitive laws and enforcement practices regarding HIV transmission, drug use, sex work, sex between men, sodomy and/or sex outside of marriage | 689 |
| THPED437 | Harm reduction, including needle and syringe programmes, opioid substitution therapy and supervised injection facilities | 695 |
| THPED629 | Gender issues and gendered relationships | 755 |
| THPED630 | Other vulnerable social groups, including in specific contexts | 755 |
| THPED631 | Gender issues and gendered relationships | 756 |
| THPED632 | Specific practices, impacts and responses for distinct substances and modes of administration (including alcohol use, injecting drug use and non-injecting drug use) | 756 |
| THPED633 | Violence, wellbeing and sex work | 756 |
| THPED634 | Female, male and transgender sex workers | 757 |

## Track E > Track E - Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors

| | | |
|---|---|---|
| THPEE438-E446 | Prevention programmes, including introduction of biomedical technologies | 695 |
| THPEE447-E456 | Early infant and adult male circumcision programmes | 698 |
| THPEE457-E501 | Successes, challenges, and results from implementing HIV testing, prevention, care and treatment programmes | 701 |
| THPEE502-E520 | Interventions to address gaps and opportunities in all steps along the HIV prevention and care continua | 716 |
| THPEE521-E523 | Interventions to enhance uptake of HIV prevention interventions e.g. voluntary medical male circumcision, condom use, pre-exposure prophylaxis (PrEP) use, post-exposure prophylaxis (PEP) use | 722 |
| THPEE524-E539 | Interventions to improve adherence to treatment and prevention behaviours and technologies | 723 |
| THPEE540-E562 | Interventions to improve retention in the prevention of vertical transmission cascade/ continuum, including early infant diagnosis and Option B+ programmes | 727 |
| THPEE563-E582 | Interventions at large scale (community, district, provincial, regional, country levels) to increase uptake of and retention in HIV services | 735 |
| THPEE583-E585 | Inpatient and outpatient services for HIV care and treatment | 741 |
| THPEE586-E587 | Migration and mobility and HIV programming | 742 |
| THPEE588-E589 | Multi-sectoral responses, including for key populations | 743 |
| THPEE590-E597 | Targeted interventions in geographic hotspots | 744 |
| THPEE598 | HIV programming for people living with disabilities | 746 |
| THPEE599-E601 | Country involvement in design and implementation of programmes | 746 |
| THPEE602 | Cross-border collaboration (between countries) to scale up access to HIV treatment and services for migrants and mobile populations | 747 |
| THPEE603 | Community coordinating mechanisms | 748 |
| THPEE604-E605 | Creating demand for HIV-related care and services | 748 |
| THPEE606-E614 | Community-led programmes and organizations, including for key populations | 749 |
| THPEE615-E619 | HIV service delivery in conflict and post-conflict settings | 751 |
| THPEE620 | Adapting HIV programmes to systems with limited health care personnel | 752 |
| THPEE621-E627 | Innovative approaches to track patients, track pre-ART care and other programme data (including connectivity and other mHealth solutions) | 753 |
| THPEE628 | Innovative approaches to sharing/ disseminating programme data at national, regional, district, site and community levels | 755 |

**Background:** Within the first weeks of human immunodeficiency virus (HIV) infection, virus replication reaches systemic circulation. Despite the critical, causal role of virus replication in determining transmissibility and kinetics of disease progression, there is limited understanding of the conditions required to transform a small localized transmitted founder population into a large and heterogeneous systemic infection.
**Methods:** Cynomolgus and rhesus macaques were infected with simian immunodeficiency virus (SIV) and followed longitudinally. Plasma levels of SIV were monitored using qRT-PCR. Bacterial genomic DNA in plasma was characterized and quantified longitudinally using 16S ribosomal deep sequencing and qPCR. ELISA-based assays were used to monitor intestinal permeability (IFABP) and perturbation of bacteria-specific host factors (sCD14 and EndoCab). Flow cytometry was used to track peripheral blood lymphocyte populations. In vitro assays were performed by exposing freshly-isolated peripheral blood mononuclear cells to bacterial lysate prepared from major translocators. Effects of bacterial lysate on CD4+ T cell activation and CD8+ T cell cytotoxicity was measured using flow cytometry. Statistical significance was calculated using ANOVA or Wilcoxon signed-rank testing.
**Results:** Prior to the peak of viremia, we observed a transient high-level influx of microbial genomic DNA into peripheral blood. This microbial translocation was accompanied by perturbation of bacteria-specific host factors in plasma, as well as expansion of the CD4+CCR5+ T cell compartment. Exposure of freshly-isolated peripheral blood mononuclear cells to lysate prepared from major translocating taxa revealed differential taxa-specific effects on the CD4+CCR5+ T cell compartment and cytotoxic granule expression within CD8+ T cells.
**Conclusions:** Altogether, our data identify the influx of microbial products into blood during hyperacute SIV infection as a candidate modifier of early interactions between the antiviral host response and nascent HIV infection. Over the next few months, we will explore the effect of inducing microbial translocation during SIV infection, with particular interest on microbial reactivity within the CD4+CCR5+ target cell compartment.

### TUAA0102

### IMPACT OF A FAT-RICH DIET ON THE PATHOGENESIS OF SIV INFECTION IN THE AFRICAN GREEN MONKEY HOST

C. Xu[1], T. He[1], G. Haret-Richter[1], D. Franck[2], B. Policicchio[1], E. Brocca-Cofano[1], D. Ma[1], J. Stock[1], R. Tracy[3], A. Landay[4], C. Wilson[2], C. Apetrei[1], I. Pandrea[1]

*Presenting author email: cux1@pitt.edu*

**Background:** High dietary fats were reported to induce intestinal dysbiosis, drive gut inflammation and breakdown the intestinal epithelial barrier, granting intestinal flora access to the bloodstream. As microbial translocation is a major determinant of the chronic immune activation and HIV/SIV disease progression, we investigated whether fat diet impacts HIV/SIV pathogenesis.
**Methods:** The nonprogressive African green monkey (AGM) model of SIV is an ideal system to assess the role of fat diet on disease progression, because they do not develop SIV-related intestinal dysfunction. We included 4 AGMs that received a fat diet prior and after SIVsab infection, and 5 controls in which the impact on key parameters of SIV infection such as: viral loads, CD4+ T cell counts, microbial translocation, immune activation and inflammation were compared and contrasted.
**Results:** LPS levels increased in the AGMs receiving fat diet prior and after SIV infection. Fat-rich diet also resulted in increases of immune activation (HLA-DR CD38, CD69 and Ki-67) and inflammation (inflammatory cytokines-IL-6, IL-17 and C reactive protein), leading to a prolonged depletion of CD4+ T cells compared to controls. However, these significant alterations of key parameters that are associated with the lack of disease progression in natural hosts of SIVs did not reach the levels described during progressive HIV/SIV infection. Furthermore, these changes did not result in significant increases in the levels of viral replication in the AGMs receiving a fat diet.
**Conclusions:** Administration of fat-rich diet resulted in alterations of markers of pathogenicity in the nonprogressive SIV infection of AGMs. Although not major, these changes were significant, suggesting that a diet very rich in fats may negatively impact HIV pathogenesis, especially if combined with other behavioral risk factors reported to impact gut integrity or systemic inflammation, such as alcohol consumption, drug usage and smoking. Detailed studies on the correlations between fat diet, alterations in the intestinal microbiota, metabolic markers, liver function and SIV progression to AIDS are in progress.

*Presenting author email: emily.wong@k-rith.org*

**Background:** Tuberculosis remains the leading cause of death in HIV-positive people. A better understanding of the impact of HIV on lung immunity may lead to novel immunotherapeutic interventions. MAIT cells are tissue-homing donor-unrestricted T cells with broad anti-microbial activity. HIV infection causes early and irreversible depletion of MAIT cells in the peripheral circulation, but the effect of HIV on MAIT cells in the lungs is unknown.
**Methods:** We FACS-sorted MAIT cells from bronchoalveolar lavage (BAL) fluid and peripheral blood of HIV-infected and HIV-negative patients from Durban, South Africa. MR1-5OPRU tetramer staining was used to identify and phenotype MAIT cells based on expression of CD3, CD4, CD8, TRAV1-2, CD161 and CD26. High throughput bias-controlled TCR sequencing (ImmunoSEQ) of sorted populations enabled detailed analysis of TCRA CDR3a usage.
**Results:** HIV infection was associated with depletion of MAIT cells in the peripheral circulation (median %5OPRU+ of CD3+CD4- lymphocytes was 1.09% in HIV-negatives, 0.34% in HIV-positives, $p = 0.027$). In contrast, MAIT cells were not depleted in the BAL compartment during HIV infection (0.68% in HIV-negatives, 0.89% in HIV-positives, p = non-significant). In HIV-negative individuals, 77.1% of circulating MAIT cells expressed the expected CD161++CD26++ phenotype, but only 43.8% of BAL MAITs expressed this phenotype ($p =< 0.0001$). In HIV infected lungs, the frequency of MAITs with the CD161++CD26++ phenotype was significantly higher (57.6%) than in HIV-negative lungs ($p=0.021$). MAIT cells with canonical MAIT TCRA CDR3a rearrangements were highly shared between donors and clonally expanded in the BALs. MAIT cells with non-canonical TCRs were unique to individuals and more frequent in HIV-infection.
**Conclusions:** We report for the first time that MAIT cells in the lungs are numerically preserved but phenotypically and clonotypically altered by HIV infection. We confirm previous reports that circulating MAIT cells are depleted in HIV. Our results suggest that peripheral MAIT cell depletions observed in HIV infection may be due to compartment-specific microbial alterations and/or tissue redistribution. Further study is needed to determine the mechanisms underlying the altered phenotypes of lung-resident MAITs and whether these can be targeted to improve anti-microbial lung immunity in people living with HIV.

### CELL-ASSOCIATED HIV-1 UNSPLICED RNA LEVEL PREDICTS BOTH TIME TO VIROLOGICAL SUPPRESSION AND DURATION OF POST-TREATMENT VIROLOGICAL CONTROL IN PATIENTS TREATED WITH TEMPORARY EARLY ART

A. Pasternak[1], J. Prins[2], B. Berkhout[1]
*[1]University of Amsterdam, Academic Medical Center, Medical Microbiology, Amsterdam, Netherlands, [2]University of Amsterdam, Academic Medical Center, Internal Medicine, Amsterdam, Netherlands*
*Presenting author email: a.o.pasternak@amc.uva.nl*

**Background:** For the improved design of strategies towards HIV-1 functional cure, it is important to identify biomarkers that could predict the duration of post-treatment virological control.
**Methods:** We studied 46 patients that received 24 or 60 weeks of temporary ART initiated at primary HIV infection (PHI). Patients were treated with a quadruple triple-class ART regimen. Cell-associated HIV-1 nucleic acids were quantified by seminested real-time PCR.
**Results:** All patients achieved virological suppression (VS) (plasma HIV-1 viremia <50 copies/ml) with a median of 21 weeks. We first assessed the predictive power of plasma viremia, total HIV-1 DNA, unspliced (US) cell-associated HIV-1 RNA, $CD4^+$ T-cell count, and CD4:CD8 ratio, measured at PHI, for the time to VS. In the univariate analysis, both plasma viremia and US RNA were predictive for time to VS (p=0.016 and p=0.0033, respectively, log-rank test). In the multivariate Cox regression, US RNA at PHI was the only significant predictor of the time to VS (HR=0.65 per 1 $\log_{10}$ increase in US RNA, 95% CI, 0.48-0.87, p=0.0043). Subsequently, the same biomarkers were longitudinally quantified every 12 weeks during ART. All 45 patients who discontinued ART experienced virological rebound (VR) (plasma viremia >50 copies/ml) within 9 months after therapy interruption. We assessed the predictive power of the last measurements of the biomarkers on ART before the therapy interruption, as well as of the duration of temporary ART, for the time to VR (the duration of post-treatment virological control). Again, US RNA was the only significant predictor of the time to VR (HR=0.29 for patients with US RNA levels below vs. above the median, 95% CI, 0.10-0.83, p=0.021, log-rank test).
**Conclusions:** In summary, in this cohort of patients treated at PHI, cell-associated HIV-1 US RNA level was the sole independent predictor of both virological suppression on ART and post-treatment virological control after ART discontinuation. Further exploration of the potential of this biomarker as a predictor of post-treatment control in large-scale clinical trials aimed at HIV functional cure is warranted.

## TUAA0105

### HIV-INFECTED PATIENTS WITH EXCEPTIONAL TCD4+ RECOVERY DURING EFFECTIVE HAART PRESENT A DISTINCT T CD4+ DIFFERENTIATION PATTERN, HIGHER CD31NEG NAÏVE CELLS AND A SMALLER HIV RESERVOIR

L. Leon-Fuentes, M. Viveros-Rogel, M. Vergara-Mendoza, M. Rodriguez-Castañón, A. Cardenas-Ochoa, A. Tello-Mercado, C. Vega, J. Sierra-Madero, L. Soto-Ramirez, S. Perez-Patrigeon
*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán (INCMNSZ), Infectious Diseases, Mexico, Mexico*
*Presenting author email: santiago.perez@infecto.mx*

**Background:** Clinical outcome of HIV infected patients relies on the recovery of CD4+ T cells after HAART. However this immune recovery is variable and difficult to predict. Here we present a cohort of patients with undetectable viral load and a follow up of 48 months of HAART who reached CD4+ T cell counts >1000 cels/$mm^3$ (Hypers) and compare them to those who reached between 350 and 999 CD4+ T cels/$mm^3$ (concordants). Their demographic data, immune recovery kinetics, and T CD4+ subsets phenotype as well as their integrated HIV DNA were analyzed.
**Methods:** Retrospective data were obtained from the charts of 447 undetectable patients on their first ARV regimen and a follow up of 48 months at the INCMSZ HIV cohort. For immune phenotype and reservoir analysis, 20 Hypers and 19 Concordants matched by sex, age and T CD4+ nadir were available. The following subsets were analyzed by Flow cytometry on whole blood: naïve T-cells, central memory T-cells, effector memory and terminally differentiated. A two-step quantitative real-time PCR (qPCR) method to detect HIV-1 integrated DNA was used, with a DNA pre-amplification using *Alu* and LTR specific primers. Proviral DNA levels were determined by a second round SYBR Green-based qPCR assay in reference to a standard curve.
**Results:** 28 Hypers (6%) and 354 concordants (79%) were identified. Hypers had a higher proportion of CD4+ naïve T-cells (37.6 vs 24.8, p< 0.05), and a low proportion of CD4+ EM T Cells (27.9 vs 39.4, p< 0.05), with similar results found in CD8+ T Cells. Hypers presented a higher percentage of CD4+CD45RA+CD31neg cells. There was no difference in total integrated HIV DNA copies per $10^6$ PBMC (1729 vs 3062, p=0.19), however the DNA/CD4 ratio of Hypers was significantly lower (1.2 vs 2.89, p<0.05).
**Conclusions:** T cell recovery of Hypers occurs very early suggesting cell redistribution, however on the long term, their T CD4+ level is driven by non-thymic-central-naïve cells that are less likely to be HIV infected, thus diluting HIV reservoir. Understanding better immune recovery after HAART and its impact on viral reservoir could contribute to design more effective therapeutic strategies.

### DYSBIOTIC BACTERIA DRIVE SUPPRESSIVE NEUTROPHIL PHENOTYPES AND PROLONGED LIFESPAN IN MUCOSAL TISSUES OF HIV-INFECTED INDIVIDUALS

T. Hensley-McBain[1], R. Cheu[2], J. Manuzak[2], A. Zevin[2], C. Miller[2], E. Lee[3], C. Wilson[3], A. Burgener[4], N. Klatt[2]

*Presenting author email: klattnr@uw.edu*

**Background:** Neutrophils infiltrate the gastrointestinal (GI) tract during HIV infection, yet their contribution to the pathology of mucosal dysfunction is unknown. In chronic HIV, blood neutrophils expressing high levels of PD-L1 suppress T cell function and correlate with T cell expression of PD-1, an exhaustion marker predictive of HIV disease progression.
**Methods:** Our study aimed to investigate whether suppressive neutrophils are also present in the colon in HIV and examined whether bacterial dysbiosis contributed to their induction. Whole blood and isolated colon biopsy leukocytes from 10-HIV infected individuals were phenotyped by flow cytometry. To examine the effects of bacterial dysbosis, whole blood was stimulated for 20 hours with HIV-altered mucosal bacteria prior to phenotyping, including *Prevotella copri*, *Prevotella stercorea, Ruminicoccus bromii,* and *Lactobacillus plantarum*.
**Results:** We found a higher frequency of PD-L1 high neutrophils in the colon compared to blood in HIV-infected individuals *(p*=0.0028). In addition, colon PD-L1 high neutrophils correlated with colon PD-1+ CD4+ T cells (*p*=0.0207). Incubation of cells with GI bacteria increased in HIV (*Prevotella spp.*), induced this PD-L1 high phenotype in neutrophils. Conversely, the beneficial GI bacteria decreased in HIV, *R. bromii,* and *Lactobacillus* did not affect PD-L1 expression. Neutrophil PD-L1 expression correlated with PD-1 expression on CD4+ T cells after bacterial sitmulation (*p*=0.0065). Finally, stimulation with *Prevotella* species reduced neutrophil apoptosis compared to the media control.
**Conclusions:** These data suggest a role for dysbiotic bacteria in reducing neutrophil homeostatic cell death and clearance and contributing to gut neutrophil infiltration in HIV. Together, these suggests that suppressive colon neutrophils may play a role in T cell exhaustion and mucosal dysfunction associated with bacterial dysbiosis and translocation in HIV, and the continual presence of neutrophils in GI tissues may be a consequence of reduced homeostatic apoptosis upon interaction with these bacteria.

# TUAB01 LONG-TERM TREATMENT SUCCESS FOR ADOLESCENTS AND YOUNG ADULTS

## TUAB0101

### RESILIENCE IN PERINATALLY HIV-INFECTED AND PERINATALLY HIV-EXPOSED ADOLESCENTS AND YOUNG ADULTS GROWING UP IN HIGH-RISK ENVIRONMENTS

C.A. Mellins[1], E.J. Abrams[2], C. Dolezal[1], P. Warne[1], K. Elkington[1], A. Bucek[1], C.S. Leu[1]
*[1]Columbia University, New York State Psychiatric Institute, New York, United States, [2]Columbia University, ICAP, Mailman School of Public Health and College of Physicians & Surgeons, New York, United States*
*Presenting author email: cam14@columbia.edu*

**Background:** Globally, pediatric HIV is increasingly an adolescent and young adult (AYA) epidemic. Research with perinatally HIV-infected (PHIV+) AYA has prioritized identification of poor health and behavioral risk outcomes, but understanding positive outcomes in spite of adversity is critical to informing evidence-based programs. Using data from a New York City longitudinal cohort study (CASAH) of PHIV+ and perinatally HIV-exposed, uninfected (PHIV-) youth, we examined psychosocial and health outcomes pertinent to understanding resilience.
**Methods:** Data are from the most recent CASAH follow-up interview (2014-2015) with 135 PHIV+ and 86 PHIV- AYA to date. Participants were recruited when aged 9-16 years (2003-2008). Psychosocial batteries are administered every 12-18

months; PHIV+ youth viral load (VL) and CD4 are abstracted from medical records. Data on psychiatric disorders, sexual behavior, substance use disorders (SUD), and young adult milestones were compared across HIV status and age groups. Descriptive statistics, and chi-square and t-tests for comparing groups were used.
**Results:** Most participants were female (55%), African-American (67%), living in impoverished communities (100%); mean age was 22 years (range 15-28). There were no HIV-status differences in rates of psychiatric disorder (28%), SUD (27%), or past 3-month condomless sex (36%). At this wave, only 29% of PHIV+AYA had a psychiatric disorder and 25% SUD. Most PHIV+ AYA aged ≥19 years had achieved young adult milestones: 78% had graduated high school, 29% taken college classes; 53% were currently working or in school; 86% had ever had sex; and 41% were in romantic relationships. Achieving milestones did not differ by HIV status. Among all PHIV+ AYA, most had positive health outcomes: CD4 ≥ 250cells/mm$^3$ (79%); CD4 ≥500cells/mm$^3$ (44%) and VL≤1000copies/ml (70%); 46% had VL< 50copies/ml. Older age was associated with CD4 < 250cells/mm$^3$ ($X^2$=7.01, df=2, p=.030) and having a psychiatric disorder was associated with VL >1000copies/ml ($X^2$=4.29, df=1, p=.038).
**Conclusions:** In one of the few ongoing US-based studies with this population, we found, despite significant biopsychosocial risks, many PHIV+ AYA have positive health and mental health outcomes and achieve AYA milestones comparable to PHIV- and other vulnerable AYA. Identification of protective factors conferring resilience can inform evidence-based practice for millions of PHIV+ youth world-wide.

## TUAB0102

### THE YOUTH TREATMENT BULGE IN SOUTH AFRICA: INCREASING NUMBERS, INFERIOR OUTCOMES AMONG ADOLESCENTS ON ART

M. Maskew[1], J. Bor[1,2], W. MacLeod[1,2], S. Carmona[3], G. Sherman[4], M.P. Fox[1,2,5]
*[1]University of the Witwatersrand, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Johannesburg, South Africa, [2]Boston University School of Public Health, Department of Global Health, Boston, United States, [3]National Health Laboratory Service, Johannesburg, South Africa, [4]National Institute for Communicable Disease, University of the Witwatersrand, Department of Paediatrics and Child Health, School of Medicine, Johannesburg, South Africa, [5]Boston University School of Public Health, Department of Epidemiology, Boston, United States*
*Presenting author email: mmaskew@heroza.org*

**Background:** Children perinatally-infected with HIV surviving due to pediatric ART are now ageing into adolescence. Yet monitoring adolescent treatment programs remains difficult as large, well-defined cohorts are rare. We quantify the size adolescent ART population and proportion virologic suppressed using a national patient cohort developed from South Africa's National Health Laboratory Service (NHLS) database.
**Methods:** Using NHLS data on all public sector viral load tests nationally since 2004, we analyzed information on all patients aged < 20 years at test date. We estimated the total number of patients accessing ART care in a given year as the number of individual patients with viral load results. Data were stratified by age and year (2004-2014) to assess shifts in age distribution on ART over time. We also assessed proportions virally suppressed in 2014, by age.
**Results:** A total of 929,274 person-years were analysed. There was a steady increase in number of children on ART under 5-years from 2004-2011, after which numbers stabilized, likely due to PMTCT successes. There were large increases in numbers of adolescents on ART, rising 10- to 20-fold from 2004-2007 to 2012-2014. Further increases are expected in 15-19 year-olds for the next decade, after which the younger cohort ageing into adolescence will decline. In 2014, the proportion virally suppressed was 71% among 5-9y (95%CI 71-72%), 65% among 10-14y (95%CI 65-66%), and 61% among 15-19y (95%CI 60-61%).
**Conclusions:** The rollout of PMTCT and pediatric ART led to a demographic bulge of HIV-infected adolescents and subsequently large numbers of adolescents receiving ART. Declining viral suppression among older adolescence suggests an urgent need to improve care for this vulnerable and growing population. Laboratory datasets represent an important tool for national and local resource planning and allocation.

| | 0-1 years | 1-4 years | 5-9 years | 10-14 years | 15-19 Years |
|---|---|---|---|---|---|
| 2004-2007 | 11,593 (15%) | 27,157 (35%) | 24,921 (32%) | 8,854 (11%) | 5,904 (8%) |
| 2008-2011 | 29,983 (9%) | 88,391 (26%) | 110,737 (33%) | 72,774 (22%) | 34,981 (10%) |
| 2012-2014 | 31,299 (6%) | 89,530 (17%) | 155,163 (30%) | 141,945 (28%) | 96,042 (19%) |

*Presenting author email: a.judd@ucl.ac.uk*

**Background:** There are limited data on the prognostic effects of time-updated covariates on long-term mortality rates of perinatally HIV-infected children after starting ART. We analysed individual patient data from 19 cohorts in 16 European countries and Thailand in EPPICC.
**Methods:** Perinatally HIV-infected children aged < 18yrs starting cART were followed until death, loss to follow-up (LTFU), transfer to adult care, their 21st birthday or last visit to 31/12/2013. Crude rates of death and first AIDS-defining events were calculated. Baseline and time-updated risk factors for death ≤/>6 months of cART and progression to AIDS were assessed using inverse-probability-censoring-weighted Cox models to account for informative censoring of LTFU.

| Variable | | Adjusted HR (95% CI) | P |
|---|---|---|---|
| Country type | Middle-income (Russia, Ukraine, Thailand) | ref | 0.028 |
| | High-income | 0.5 (0.2-0.9) | |
| Calendar year at cART start | 1997-<2004 | ref | 0.035 |
| | 2004-<2008 | 0.4 (0.2-0.8) | |
| | ≥2008 | 0.5 (0.1-1.5) | |
| BMI-for-age z-score at cART start | >0 | 0.2 (0.1-0.6) | 0.045 |
| | -3 to 0 | ref | |
| | <-3 | 0.5 (0.2-1.6) | |
| VL copy-years suppressed (≤400c/ml) since cART initiation (per year increase) | | 0.7 (0.6-0.9) | 0.001 |
| Current (time updated) age (years) | <2 | 4.2 (1.4-12.7) | 0.002 |
| | 2-<5 | 0.2 (0.1-1.8) | |
| | 5-<14 | ref | |
| | ≥14 | 2.1 (1.0-4.2) | |
| Current (time updated) WHO immune stage severe | No | 0.1 (0.1-0.2) | <0.001 |
| | Yes | ref | |
| Current (time updated) BMI-for-age z-score | >0 | 1.1 (0.4-2.8) | <0.001 |
| | -3 to 0 | ref | |
| | <-3 | 19.5 (7.2-52.8) | |

*[Table: Predictors of death >6 months of cART]*

**Results:** Of 3527 children, 32%, 20%, 18% and 30% were from the UK/Ireland, Thailand, Russia/Ukraine, and the rest of Europe respectively. At cART initiation, median (IQR) age was 5.2(1.4-9.3) years and 42% had severe WHO immunological stage. Median follow-up was 5.6(2.9-8.7) years. There were 94 deaths and 174 first AIDS-defining events, of which 43(46%) and 79(45%) occurred within 6 months of cART

**Tuesday 19 July** Oral Abstract Sessions

Wednesday 20 July

Thursday 21 July

Friday 22 July

Author Index

initiation. The crude mortality rate was 2.50[95%CI 1.86-3.38]/100 person-years (PY) in the ≤6 month period, and 0.27[0.21-0.36] thereafter. 59(63%) {31≤6 months} deaths were from HIV-related infections, 19(20%) {9} HIV-related non-infectious conditions, 12(13%) {1} HIV-unrelated, and 4(4%) {2} unknown. The rate of first AIDS-defining event was 0.88[0.76-1.02]/100PY, including 31(18%) HIV encephalopathy, 29(17%) tuberculosis and 25(14%) HIV wasting syndrome. The Table shows multivariable predictors of increased risk of death >6 months of cART. Predictors for death ≤6 months (baseline only) and progression to AIDS (baseline and time-updated) were broadly similar.

**Conclusions:** Almost half of deaths occurred ≤6 months of cART, after which current severe WHO immune stage, low BMI-for-age z-score, and fewer VL copy-years suppressed were the strongest predictors for mortality. The raised mortality risk in those age≥14 and in middle-income countries raises concern.

## TUAB0104

### WHAT DOES ADOLESCENT TRANSITION MEAN IN SUB-SAHARAN AFRICA? PREDICTORS OF TRANSFER IN SOUTHERN AFRICAN PERINATALLY HIV-INFECTED ADOLESCENTS

*[1]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, [2]University of Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [3]Harriet Shezi Children's Clinic, Johannesburg, South Africa, [4]Lighthouse Trust Clinic, Lilongwe, Malawi, [5]University of Stellenbosch, Tygerberg Academic Hospital, Stellenbosch, South Africa, [6]University of Cape Town, Red Cross Children's Hospital and Department of Paediatrics, Cape Town, South Africa, [7]Kheth'Impilo, Cape Town, South Africa, [8]University of Witwatersrand, Empilweni Services and Research Unit, Rahima Moosa Mother and Child Hospital, Johannesburg, South Africa, [9]University of KwaZulu Natal, Africa Centre for Health and Population Studies and Hlabisa ART Programme, Somkhele, South Africa, [10]University of Cape Town, Gugulethu Community Health Centre and Desmond Tutu HIV Centre, Institute of Infectious Diseases and Molecular Medicine, Cape Town, South Africa, [11]McCord Hospital, Durban, South Africa, [12]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [13]Newlands Clinic, Harare, Zimbabwe, [14]Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), Maternal and Pediatric Infectious Disease Branch, Bethesda, United States, [15]University of Bern, Institute of Social & Preventive Medicine (ISPM), Bern, Switzerland, [16]Médecins Sans Frontières and Khayelitsha ART Programme, Khayelitsha, South Africa*

*Presenting author email: mary-ann.davies@uct.ac.za*

**Background:** In wealthy countries, many perinatally HIV-infected adolescents (PHA) transition from specialist pediatric clinics to adolescent/adult clinics during late adolescence. Transition may differ in sub-Saharan Africa, where pediatric HIV care is mostly provided in decentralized non-specialist primary care clinics either from antiretroviral therapy (ART) start or soon thereafter once children are stable on treatment. We examined transfer patterns in PHA in Southern Africa.

**Methods:** We included presumed PHA (ART initiation at < 9.5 years old without documented non-perinatal infection) with follow-up after 10 years of age at 12 IeDEA-SA cohorts providing pediatric ART care from Malawi, South Africa, Zambia and Zimbabwe from 2000-2014. We described characteristics at ART initiation, and at transfer or last visit in those remaining in care (RIC) at their original site. We used Cox proportional hazards models to identify predictors of transfer.

**Results:** We excluded 1660 PHA from 2 cohorts where no children transferred. Among 3820 children included, estimated probability of transfer by age 13 years varied widely between sites from 5.1% to 54.3%. Transfer was higher from specialist pediatric facilities compared to primary care facilities. At transfer, the median age was 11.4 years; 82% of children had CD4 >500 cells/μl and 89% had HIV-RNA < 400 copies/ml (Table).

| | RIC (n=2650) (excludes 253 children deceased or LTFU) | TFO (n=917) | p-value |
|---|---|---|---|
| Female (n/N; %) | 1260/2650; 48% | 439/917; 48% | 0.865 |
| Median (IQR) age in years at ART start | 7.2 (5.6-8.4) | 7.1 (5.4-8.3) | 0.195 |
| WHO-defined severe immunosuppression at ART start (n/N; %) | 993/1461; 68% | 433/627; 69% | 0.623 |
| Median (IQR) age (yrs) at TFO or last visit if RIC | 12.1 (10.9-13.8) | 11.4 (10.6-12.7) | <0.001 |
| Median (IQR) CD4 (cells/μl) at TFO or last visit if RIC | 725 (518-950) | 779 (569-1032) | <0.001 |
| CD4 >500 cells/μl at TFO or last visit if RIC (n/N; %) | 1566/2036; 77% | 656/801; 82% | 0.004 |
| Height-for-age z-score <-2 at TFO or last visit if RIC (n/N; %) | 355/906 ; 39% | 221/543; 41% | 0.568 |
| HIV-RNA <400 copies/ml (n/N; %) | 1543/2117; 73% | 694/781; 89% | <0.001 |

*[Characteristics of children with presumed perinatal HIV infection who remain in care at the original site (RIC) or are tranferred out (TFO)]*

After adjusting for site, PHA with the following characteristics were more likely to transfer: longer ART duration at 10 years (adjusted Hazard Ratio [aHR] 1.29, 95% Confidence Interval [CI]: 1.22-1.35), not severely immunodeficient at ART start (aHR 1.25; 95%CI:1.03-1.52), CD4 >500 cells/μl at age 10 (aHR 1.30; 95%CI:1.01-1.6), HIV-RNA < 400 copies/ml at age 10 (aHR 1.38; 95%CI:1.05-1.82).

**Conclusions:** Transfer patterns differ considerably between cohorts with many children transferring during early adolescence. PHA were relatively well at transfer; more than 80% had CD4 >500 cells/ul and virologic control. Understanding transfer patterns and tracking outcomes after transfer is important to comprehensively evaluate PHA outcomes.

## TUAB0105LB

### SWITCHING TO SECOND-LINE ANTIRETROVIRAL THERAPY (ART) IN HIV-INFECTED CHILDREN: A CIPHER COHORT COLLABORATION GLOBAL ANALYSIS

I.J. Collins, Collaborative Initiative for Paediatric HIV Education and Research (CIPHER) Cohort Collaboration Duration of First-line Team

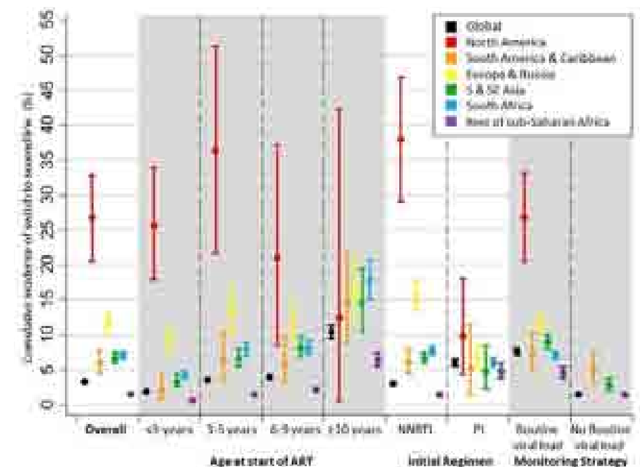
*MRC Clinical Trials Unit at UCL, Institute of Clinical Trials & Methodology, London, United Kingdom*

*Presenting author email: jeannie.collins@ucl.ac.uk*

**Background:** There are conflicting data on time to switch from first-line to second-line ART in children. Here we present the first global estimates.

**Methods:** Individual-level data were pooled from 12 cohort networks within CIPHER. Children aged < 18-years initiating combination ART (≥2 nucleoside reverse-transcriptase inhibitors (NRTI) plus non-NRTI (NNRTI) or boosted protease inhibitor (PI)) were included. Switch to second-line was defined as: (i) change of ≥1 NRTI plus either change in drug class (NNRTI to PI or vice versa) or PI change; (ii) change from single to dual PI; or (iii) addition of new drug class. Cumulative incidence curves assessed time to switch, with death and loss to follow-up (LTFU) as competing risks.

**Results:** Of 95,194 children included, 18% were from South Africa and 72% from rest of Sub-Saharan Africa (SSA). At ART start, median [IQR] age was 3.7[1.6-6.8] years, CD4% 15%[9-21%], 42% had AIDS, 89% and 11% initiated NNRTI-based and PI-based ART, respectively. Median duration of follow-up from ART initiation was 26[9-51] months; 1% died, 26% were LTFU and 20% transferred out. Overall 4266 (4.5%) switched to second-line at median of 33.8[18.5, 55.1] months. The proportion switching at 3-years after ART start varied significantly across regions from 1.6% (95% CI 1.5,1.7) in SSA to 26.8% (20.6,33.3) in North America (Figure). A higher incidence of switch was seen in children aged≥10yrs at ART start compared to younger children in all regions except North America, in settings with routine viral load monitoring, and in children initiating NNRTI-based ART compared to PI-based ART in all regions except SSA.



*[Figure. Cumulative incidence of switch at 3 years of ART by age at start of ART, initial regimen and monitoring strategy by region]*

**Conclusions:** We found wide regional variations in the cumulative incidence of switch to second-line, with higher incidence among children initiating ART aged≥10 years and those in settings with routine viral load monitoring. High rates of transfer and LTFU mean these estimates maybe the lower bound of the true switch rates.

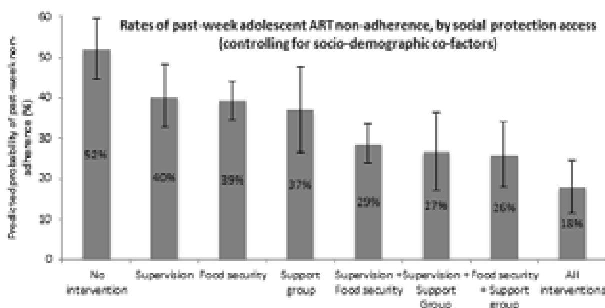
# TUAB02 CLUBS, CASH AND CAREGIVERS: IMPACT ON ADHERENCE AND RETENTION

## TUAB0201

### CASH, CARE AND HIV-COMMUNITY: SOCIAL PROTECTION IMPROVES ADOLESCENT ART-ADHERENCE IN SOUTH AFRICA

L. Cluver[1,2], E. Toska[2], M. Orkin[3], A. Yakubovich[2], R. Hodes[1], L. Sherr[4]
*[1]University of Cape Town, Cape Town, South Africa, [2]University of Oxford, Social Policy and Intervention, Oxford, United Kingdom, [3]University of the Witwatersrand, DST-NRF Centre of Excellence in Human Development, Johannesburg, South Africa, [4]University College London, London, United Kingdom*
*Presenting author email: lucie.cluver@spi.ox.ac.uk*

**Background:** Low ART-adherence amongst adolescents causes morbidity, mortality and onwards HIV-transmission. Reviews find no effective adherence-promoting interventions. This study examines associations of seven potential social protection factors with adherence, in the world's largest community sample of HIV+ adolescents.
**Methods:** N=1059 adolescents: all 10-19 year olds ever ART-initiated in 53 government healthcare facilities in a health district of South Africa's Eastern Cape were traced and interviewed in 2014-15. 90.1% of the eligible sample was included (4.1% adolescent or caregiver refused, 0.9% severe cognitive disability, 1.2% excluded and 3.7% unable to trace). Potential social protection predictors were 'cash': food security, school fees/materials, clothing; and 'care': HIV support group, sports group, positive parenting and high parental supervision. Analyses used multivariate regression with all potential predictors entered simultaneously, interaction and marginal effects models in SPSS and STATA.
**Results:** Past-week self-reported ART non-adherence was 36%, associated with increased opportunistic infections
(p< .002 SD.09). Postnatally-infected and rural adolescents were at highest risk, age and gender did not predict adherence. Analyses controlled for covariates: age, gender, location, perinatal/postnatal infection, treatment duration, ethnicity, maternal/paternal death, distance to clinic and general health. Independent of these, three cash and care social protection factors were associated with reduced non-adherence: food security (2 meals/day) (OR.60, CI.44-.81, p< .001); high parental/caregiver supervision (i.e. monitoring of adolescent activities) (OR.62, CI.47-.82, p< .001); and attending an HIV support group (OR.54, CI.36-.83, p< .004). Effects of combination social protection were not multiplicative, but were additive in predicted probabilities controlling for co-factors. With no protection factors, non-adherence was 52%, with any one protection it was 37-40%, and with all three social protections, 18%.



*[Rates of past-week adolescent ART non-adherence, by social protection access (controlling for socio-demographic co-factors)]*

**Conclusions:** Combination social protection 'cash plus care' improves adolescent ART-adherence. Specifically, food security, parenting support programmes and expanded provision of HIV support groups have potential to improve adherence, and subsequently adolescent HIV-survival and HIV-prevention.

## TUAB0202

### THE EFFECT OF COMMUNITY ART GROUPS ON RETENTION-IN-CARE AMONG PATIENTS ON ART IN TETE PROVINCE, MOZAMBIQUE

T. Decroo[1], B. Telfer[1], C. Das Dores[2], B. Candrinho[2], N. Dos Santos[1], A. Mkwamba[1], S. Dezembro[1], M. Jofrisse[1], T. Ellman[3], C. Metcalf[3]
*[1]Médecins Sans Frontières, Tete, Mozambique, [2]Direcção Provincial de Saúde, Tete, Mozambique, [3]Médecins Sans Frontières, Southern Africa Medical Unit, Cape Town, South Africa*
*Presenting author email: tomdecroo2@gmail.com*

**Background:** ART programs in many African countries have high attrition rates (death or loss-to-follow-up (LTFU) combined). In 2008 patients on ART in Tete Province, Mozambique, began forming community ART groups (CAGs) to overcome barriers to retention-in-care (RIC). CAGs are peer groups in which members take turns to collect ART at the health facility. Patients on ART can either join a CAG or remain in clinic based care. We conducted a retrospective cohort study among adult patients on ART to quantify the effect of CAG versus individual care on RIC.
**Methods:** Information to May 2012 was collected from patient records at eight health facilities. Patients who started ART ≥6 months before CAGs started at a health facility, or aged < 15 years at ART initiation, were excluded. Furthermore, patients had to remain in care for at least six months after starting ART to be included in the analysis. Survival analysis was used to compare RIC among patients in CAGs and patients in individual care, with time to joining a CAG treated as an irreversible time-dependent covariate. Cox regression was used to determine hazard ratios (aHR) for attrition, adjusted for age, gender, and health facility.
**Results:** Of the 2,683 patients in the analysis, 62.6% were female. The median age was 32 years. 12-month and 24-month RIC from point of eligibility were respectively 99.3% (95% CI: 97.8% - 99.8%) and 96.3% (95% CI: 94.4% - 97.6%) and among patients in CAGs, and 89.0% (95% CI: 87.3% - 90.2%) and 81.3% (95% CI: 78.8% - 83.4%) among those in individual care (p < 0.001). CAG patients were more than four times less at risk to die or to be LTFU (aHR = 0.22; 95% CI: 0.15 - 0.32; p< 0.001).
**Conclusions:** RIC was substantially better among patients on ART in CAGs than those in individual care. While exclusion of the first 6 months on ART reduced the potential impact of survivor bias, residual confounders may contribute to the differences observed. Nevertheless this study confirms that patient-led ART distribution through CAG results in high RIC, and supports the Mozambique Ministry of Health decision to implement CAG nationally.

## TUAB0203

### ONE YEAR RETENTION IN COMMUNITY VERSUS CLINIC-BASED ADHERENCE CLUBS FOR STABLE ART PATIENTS IN SOUTH AFRICA: FINDINGS FROM A RANDOMIZED CONTROLLED TRIAL

C. Hanrahan[1], V. Keyser[2], S. Schwartz[1], P. Soyizwaphi[2], N. West[1,2], L. Mutunga[2], J. Steingo[2], J. Bassett[2], A. Van Rie[3,4]
*[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Witkoppen Health and Welfare Centre, Johannesburg, South Africa, [3]University of Antwerp, Antwerp, Belgium, [4]University of North Carolina Gillings School of Global Public Health, Chapel Hill, United States*
*Presenting author email: lillianm@witkoppen.co.za*

**Background:** Adherence clubs, where groups of 25-30 patients stable on antiretroviral therapy (ART) meet for counselling and medication pick-up, is an innovative model to retain patients in care and facilitate task-shifting. Adherence clubs can be organized at a clinic or community venue. We performed a randomized controlled trial to compare club retention between community and clinic-based adherence clubs.
**Methods:** Stable patients with undetectable viral load at Witkoppen Health and Welfare Centre, in Johannesburg, South Africa, were randomized to either a clinic- or community-based adherence club. Clubs were held every other month and were run by an HIV counsellor. All club participants received annual viral load monitoring and annual medical exam by a clinician at the clinic. Patients became ineligible for club participation and were referred back to routine care if they missed a club visit without ART pickup within 5 days, had two consecutive late ART pickups, developed a comorbidity requiring closer monitoring, or had viral rebound. We compared the proportion referred back to routine care between clinic and community-based clubs in the first 12 months of club participation.
**Results:** From February 2014-May 2015, we randomized 770 adults into 12 pairs of clubs-- 378 (49%) clinic-based, and 392 (51%) community-based. Characteristics were similar by arm: 66% female, 88% on fixed-dose combination ART, and median CD4 count of 502 cells/mm$^3$. The proportion referred back to routine care was greater among community-based clubs (26%, n=102) compared to clinic-based clubs (19%, n=70, p=0.012) (Figure). Viral rebound was uncommon and comparable by club type (3% in clinic and 2% in community, p=0.594). Among those referred

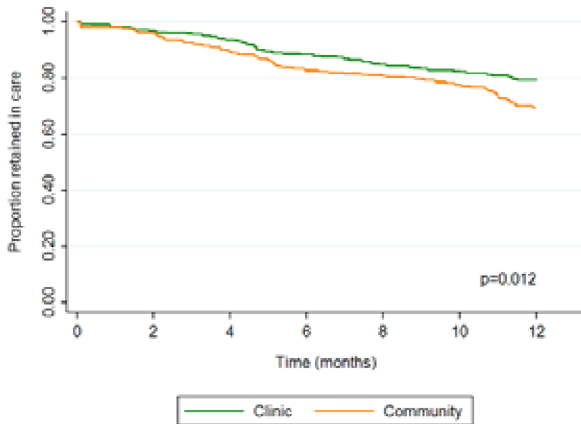
Late Breaker Posters

Author Index

back to routine care, missing a club visit was the most common reason in both club types (61%).

**Conclusions:** Within the first year of adherence club participation, drop out was higher among community-based compared to clinic-based clubs.



[Retention in adherence club care--community vs clinic-based clubs]

### IMPROVED ADHERENCE TO ANTIRETROVIRAL TREATMENT OBSERVED AMONG CHILDREN WHOSE CAREGIVERS HAD POSITIVE BELIEFS IN MEDICINE

G. Abongomera[1,2], A. Cook[3], M. Lamorde[4], C. Chabala[5], V. Musiime[1], M. Thomason[3], V. Mulenga[5], R. Colebunders[2], C. Kityo[1], S. Walker[3], D.M. Gibb[3], on behalf of the CHAPAS-3 Trial Team

*[1]Joint Clinical Research Centre, Kampala, Uganda, [2]University of Antwerp, Antwerp, Belgium, [3]Medical Research Council Clinical Trials Unit, London, United Kingdom, [4]Infectious Diseases Institute, Kampala, Uganda, [5]University Teaching Hospital, Lusaka, Zambia*

*Presenting author email: gabongomera@jcrc.org.ug*

**Background:** CHAPAS-3 trial investigated how the views of the child's caregiver towards medicine affected the adherence of their child to fixed-dose combination ART.

**Methods:** 478 HIV-infected children aged one month to 13 years were randomized to one of three first-line ARTregimens in Uganda and Zambia. Children were ART naïve (n=365) or ART experienced (n=113) at enrolment. We measured adherence to ART using medication event monitoring systems (MEMS) caps, and caregivers' views towards all medicines and medicines currently prescribed using the Beliefs in Medicine Questionnaire (BMQ). MEMS caps data were collectedduring weeks 0-18 and 54-72. The BMQ was completed by caregivers at weeks 0, 6, 24, 48, 72 and 96. We used repeated measures linear regression models to investigate associations between MEMS adherence in weeks 0-18 and BMQ at weeks 0 and 6 (period 1), and MEMS adherence in weeks 54-72 and BMQ in week 48 (period 2).

**Results:** MEMS adherence and BMQ data were available from 271/365 (74%) ART naïve and 97/113 (86%) ART experienced children in period 1, and 235/335 (70%) naïve and 98/112 (88%) experienced children in period 2. We present results from the ART naïve group in period 1, similar results were observed in period 2, and also among ART experienced children. Caregivers belief in the necessity of ART was stronger on average than their concern, median (IQR) scores were 20.0 (19.3,21.7) and 12.0 (10.7,14.7) for necessity and concern respectively. The median (IQR) necessity-concern differential was 8.3 (6.7,9.7). Adherence was good, as measured by MEMS, with median (IQR) 92% (84%,96%) doses taken. A significant positive association was observed between high necessity-concern score and high mems adherence, p=0.028 (β=0.236). A significant association was also seen among naïve children in period 2 (p< 0.001) but not among ART experienced children.

**Conclusions:** Caregivers of HIV-infected children had a strong belief in the necessity of ART, outweighing their concerns about treatment. High levels of adherence to ART were associated with positive overall beliefs towards medicine.There is a need of emphasizing the necessity of treatment to caregivers, while addressing any concerns they may have about ART.

## TUAB0205

### IS RETENTION ON ART UNDERESTIMATED DUE TO PATIENT TRANSFERS? ESTIMATING SYSTEM-WIDE RETENTION USING A NATIONAL LABS DATABASE IN SOUTH AFRICA

M. Fox[1,2], J. Bor[3], W. MacLeod[3], M. Maskew[2], A. Brennan[3], W. Stevens[4], S. Carmona[4]

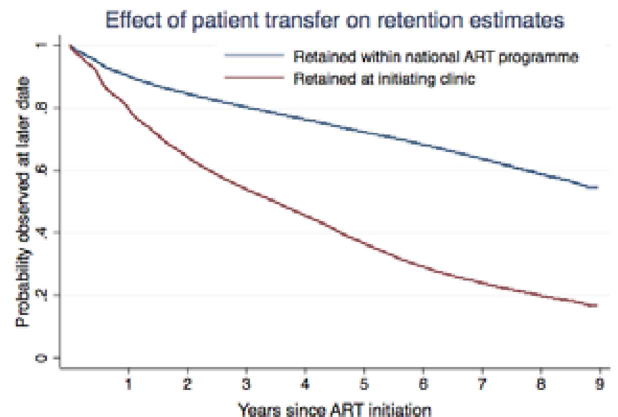
*[1]Boston University, School of Public Health, Departments of Epidemiology and Global Health, Boston, United States, [2]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]Boston University, School of Public Health, Department of Global Health, Boston, United States, [4]National Health Laboratory Service, Johannesburg, South Africa*

*Presenting author email: mfox@bu.edu*

**Background:** Systematic reviews have described high rates of attrition in patients receiving antiretroviral therapy (ART). However, migration and clinical transfer may lead to overestimation of attrition. Using a newly linked national laboratory database in South Africa, we assessed system-wide retention in care.

**Methods:** South Africa's National Health Laboratory Service maintains a database of all public sector CD4 count and viral load (VL) test results since 2004. We developed an algorithm to link individual lab results using probabilistic matching techniques, creating a national cohort of HIV patients. We analyzed data on all patients initiating ART in 2004 and 2005 (during which time VL were collected at ART initiation) and who had at least one subsequent lab result. We assessed retention in care as *time to a patient's most recent lab result* (CD4 or VL), following patients through March 2015. Patients were identified as still in care if their last lab test occurred April 2013 - March 2015. We assessed two retention concepts: (a) *system-wide retention* including all lab results regardless of testing facility and (b) *retention at the initiating clinic,* in which lab tests at other facilities were ignored. These two concepts mirror the information available on patient histories from clinic-based and health system-wide perspectives.

**Results:** We followed 53,880 patients who initiated ART in 2004 and 2005. Eight-year retention at the initiating clinic was 13.1% (95%CI: 12.9-13.4). After allowing for transfers, system-wide eight-year retention increased to 47.3% (95%CI 46.9-47.7)(Figure).



[Figure 1 - Effect of patient transfer on retention estimates]

**Conclusions:** Patient migration and transfer are common throughout sub-Saharan Africa. Whereas prior cohort studies have tracked patients through resource-intensive follow-up, we show the utility of a national laboratory database for passive tracking of patients regardless of where they seek care. These findings have implications not just for measurement, but also potential to improve continuity of patient care in migration populations.

### Oral administration of maraviroc, in infant rhesus macaques, fails to prevent SIVmac oral transmission

E. Brocca-Cofano[1,2], C. Xu[3,4], D. Ma[3], B.B. Policicchio[3,5], K.D. Raehtz[3,4], T. Dunsmore[3], G.S. Haret-Richter[2,3], C. Sykes[6], B.F. Keele[7], A.D.M. Kashuba[6,8], I. Pandrea[2,3,5], C. Apetrei[3,4,5]
*[1]University of Pittsburg, Center for Vaccine Research,, Pittsburgh, United States, [2]University of Pittsburgh, Department of Pathology, Pittsburgh, United States, [3]Center for Vaccine Research, University of Pittsburg, Pittsburgh, United States, [4]University of Pittsburgh, Department of Microbiology and Molecular Genetics, Pittsburgh, United States, [5]University of Pittsburgh, Microbiology and Infectious Diseases, Graduate School of Public Health, Pittsburgh, United States, [6]Eshelman School of Pharmacy, Chapel Hill, United States, [7]National Cancer Institute, Frederick, United States, [8]School of Medicine, University of North Carolina, Chapel Hill, United States*
*Presenting author email: cofano@pitt.edu*

**Background:** HIV maternal-to-infant-transmission (MTIT) accounts for >300,000 cases annually. New strategies of prevention are needed. SIV target cell availability at mucosal sites was reported to drive virus transmission. We investigated if systemic CCR5 blockade with Maraviroc (MVC) impacts oral SIV transmission to infant rhesus macaques (RMs).
**Methods:** Nine infant RMs aged six months were included. Four RMs were untreated controls and five RMs received MVC (150 mg/kg/bid/orally) for up to 6 months. Coreceptor occupancy was closely monitored and RMs were orally exposed to 10,000 TCID50 of SIVmac766XII every two weeks, up to 6 times. The concentration of MVC in plasma was measured by validated LC-MS/MS, plasma viral loads (VLs) and changes of immune cells were monitored respectively by RT-PCR and flow cytometry.
**Results:** MVC was well tolerated by RMs, with no adverse reactions and significantly blocked CCR5 coreceptor compared to control group (I challenge p=0.0159, II challenge p=0.0317 and III challenge p=0.0286). All RMs in the control group and 60% of those receiving MVC became infected (p=0.1515). No difference in the number of exposures needed to infect RMs in the two groups was observed. At the time of viral exposure, MVC plasma concentrations were of 538.36±422.56 ng/mL, within the range seen in humans receiving MVC. All treated and control RMs were infected with one viral variant, suggesting that the animals were not overexposed to virus, which might have offset MVC protective effect. Ramp-up viremia was significantly delayed (p=0.05) in the MVC-treated RMs. Peak (MVC-treated 7.18 log; control 6.71 log) and postpeak (MVC-treated 5.49 log; control 5.29 logs) VLs were similar in both groups. No significant differences in $CD4^+$ T cell depletion or in the levels of immune activation were observed between the two groups.
**Conclusions:** MVC effectively blocked CCR5 and was well tolerated in infant RMs. Yet, CCR5 blockade with MVC did not significantly impact SIV oral transmission. Since SIVmac is more promiscuous than HIV-1 with regard to coreceptor usage (i.e., being able to use alternative coreceptors, such as BOB/GPR15 and Bonzo/STRL33), CCR5 blockade in humans might be more effective in preventing MTIT alone or in combination with other antiretroviral drugs.

## TUAC0102

### HPTN 069/ACTG A5305: Phase II study of maraviroc-containing regimens for HIV PrEP in United States (U.S.) women

R. Gulick[1], T. Wilkin[1], Y. Chen[2], R. Landovitz[3], R. Amico[4], A. Young[2], P. Richardson[5], M. Marzinke[5], C. Hendrix[5], S. Eshleman[5], I. McGowan[6], A. Andrade[5], S. Hodder[7], K. Klingman[8], W. Chege[8], A. Rinehart[9], J. Rooney[10], P. Andrew[11], M. McCauley[12], K. Mayer[13], HPTN 069/ACTG 5305 Study Team
*[1]Weill Cornell Medicine, New York City, United States, [2]Fred Hutchinson Cancer Research Center, Seattle, United States, [3]University of California, Los Angeles, United States, [4]University of Michigan School of Public Health, Ann Arbor, United States, [5]Johns Hopkins University School of Medicine, Baltimore, United States, [6]University of Pittsburgh School of Medicine, Pittsburgh, United States, [7]West Virginia University School of Medicine, Morgantown, United States, [8]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [9]ViiV Healthcare, Durham, United States, [10]Gilead Sciences, Foster City, United States, [11]FHI 360, Durham, United States, [12]FHI 360, Washington, United States, [13]The Fenway Institute, Boston, United States*
*Presenting author email: rgulick@med.cornell.edu*

**Background:** Maraviroc (MVC) is an HIV entry inhibitor that concentrates in the genital tract/rectum, making it a potential PrEP agent.
**Methods:** Prospective, randomized, double-blinded, multisite, safety/tolerability study of 4 regimens for HIV PrEP: (1) MVC alone; (2) MVC + emtricitabine (FTC); (3) MVC + tenofovir (TDF); (4) TDF + FTC. Study regimens consisted of 3 pills once-daily -- MVC 300 mg, FTC 200 mg, TDF 300 mg, with matching placebos. Eligible participants were adult HIV-uninfected women who reported a history of condomless vaginal or anal intercourse with ≥1 HIV-infected or unknown-serostatus man within 90 days of screening, and had adequate safety laboratory parameters including calculated creatinine clearance ≥70 ml/min. Participants were randomized to study regimens for 48 weeks with follow-up visits at weeks 2, 4, 8, and then every 8 weeks. At each visit, history, physical exam, safety laboratories, blood plasma for drug concentrations, adherence counseling, and HIV testing were conducted. All analyses were intent-to-treat.
**Results:** 12 HPTN and ACTG sites enrolled 188 women with a median age of 35 (range 18-61), including 65% black, 27% white, and 17% Latina participants. 153 (81%) completed study follow-up; 15 (8%) were lost to follow-up. 37 (20%) permanently discontinued the study regimen early, including 16 (8%) for participant request and 10 (5%) for pregnancy; rates and times to study drug discontinuation did not differ among the study arms (both p>0.2). MVC-alone was associated with fewer grade 2-4 adverse events than either TDF-containing regimen (p< 0.01); MVC+FTC was associated with fewer events than MVC+TDF (p=0.02). In a random subset of participants (n=125) at random study time points, 66% had detectable study drug plasma concentrations. 4 women had sexually transmitted infections while on study (3 chlamydia, 1 gonorrhea.) No HIV infections were identified during the study; the annual HIV incidence in women on this study was 0% [95% CI: 0%, 2.5%].
**Conclusions:** In this study of HIV PrEP in women, MVC-containing regimens were safe and well-tolerated compared to the control regimen of TDF+FTC. Only 2/3 had detectable study drug concentrations, but no HIV infections were identified. MVC-containing regimens should be explored further as oral PrEP for women.

## TUAC0103

### Persistence of rilpivirine following single dose of long-acting injection

I. McGowan[1], A. Siegel[2], J. Engstrom[2], A. Nikiforov[2], K. Duffill[2], S. Edick[1], C. Mitchell[1], D. Back[3], L. Else[3], D. Egan[3], S. Khoo[3], P. Williams[4], R.M. Brand[1], R.D. Cranston[1]
*[1]University of Pittsburgh, School of Medicine, Pittsburgh, United States, [2]Magee-Womens Research Institute, Pittsburgh, United States, [3]University of Liverpool, Liverpool, United Kingdom, [4]Janssen Pharmaceuticals, Beerse, Belgium*
*Presenting author email: imcgowan@pitt.edu*

**Background:** Long-acting (LA) injectable formulations of rilpivirine (RPV) and cabotegravir (CAB) are currently being evaluated for the treatment and prevention of HIV infection. It is possible that, following completion of the PrEP dosing regimen with an LA agent, participants may experience an extended period of exposure to declining antiretroviral concentrations. Individuals who acquire HIV infection during this period may be at risk of developing resistance to the agent. To mitigate this risk, the HPTN-083 Phase 2B/3 study of CAB LA PrEP is proposing to provide study participants with 12 months of oral PrEP to cover the LA PK tail. However, there is an urgent need to better define the PK tail for LA PrEP agents.
**Methods:** The MWRI-01 study was undertaken to characterize the safety, acceptability, pharmacokinetics (PK), and pharmacodynamic profile of RPV LA. Participants from the single dose (SD) phase of evaluation of RPV (600 mg and 1200 mg) were able to enroll in a multiple dose (MD) phase evaluation of RPV (1200 mg). This study design provided an opportunity to characterize the persistence of RPV in baseline plasma samples obtained from participants enrolled in the MD phase of the MWRI-01 study. The Lower Limit of Quantification for RPV was 0.5ng/mL. Multiple blanks were included in the PK assays to exclude the possibility of carryover contamination.
**Results:** Eight women and four men were enrolled in the MD phase of the study of whom 9/12 (75%) had participated in the SD phase of the study (Table 1). RPV was detected in baseline plasma samples all five female participants (Mean RPV concentration 4.8 ± 2.9 ng/mL) and 3/4 of the male participants (Mean RPV concentration 2.9 ± 1.6 ng/mL). The mean time interval between the SD and Baseline visit was 536 ± 182 and 591 ± 78 days respectively for the female and male participants.

| Sex | Single Dose (SD) of RPV | Plasma RPV at 24 hours after SD RPV (ng/mL) Mean (± STD) | Time (Days)between SD and Multiple Dose (MD) Baseline Visit Mean (± STD) | Plasma RPV at MD Baseline Visit (ng/mL) Mean (± STD) |
|---|---|---|---|---|
| Male | 600 mg (N=2) | 20.9 (12.3) | 630 (100) | 0.8 (0.8) |
| | 1200 mg (N=2) | 18.2 (3.7) | 553 (51) | 3.7 (1.1) |
| Female | 1200 mg (N=5) | 54.0 (12.1) | 536 (182) | 4.8 (2.9) |

*[Table 1 Summary of time interval between single dose RPV and baseline PK]*

**Conclusions:** SD administration of RPV LA was associated with prolonged and declining PK exposure. These data have significant implications for the design of LA PrEP studies.

## TUAC0104

### BENEFITS OF PRE-EXPOSURE PROPHYLAXIS RELATIVE TO DRUG RESISTANCE RISK

R. Grant[1,2,3], V. Fonner[4], M. Rodolph[2], T. Liegler[5], D. Glidden[5], R. Baggaley[2]
*[1]Gladstone Institutes, San Francisco, United States, [2]World Health Organization, Geneva, Switzerland, [3]San Francisco AIDS Foundation, San Francisco, United States, [4]Johns Hopkins University, Baltimore, United States, [5]University of California, San Francisco, United States*
*Presenting author email: robert.grant@ucsf.edu*

**Background:** The risk of drug resistance (DR) with FTC/TDF or TDF pre-exposure prophylaxis (PrEP) occurs primarily in people who had acute HIV infection when starting or restarting PrEP. The risks and benefits of RNA testing before starting PrEP have not been determined.
**Methods:** The risk of DR in PrEP programs was compiled across 6 randomized clinical trials and one demonstration project. Resistance was measured using clinical genotypic tests.
**Results:** All reviewed trials used rapid 2nd or 3rd generation antibody tests to guide PrEP initiation, and retrospectively analyzed baseline specimens for HIV RNA among seroconverters. FTC DR occurred in 10 participants who received FTC/TDF PrEP, including 33% (5/15) of participants acutely infected when starting PrEP, and in 3% (5/157) of participants with emergent infection. Including both baseline and emergent infections, there were 172 infections in the FTC/TDF arms compared with 270 among corresponding placebo controls, representing 98 infections averted and 10 (98/10) infections averted for every FTC resistant infection. Tenofovir resistance occurred in 1 participant who received TDF PrEP, including 10% (1/10) of participants acutely infected when starting PrEP, and none (of 90) with emergent infection. There were 100 infections in the TDF arms and 153 infections in the placebo controls, representing 53 infections averted by TDF PrEP and 53 (53/1) infections averted for every tenofovir resistant infection. In the demonstration project, a screen for acute viral symptoms led to deferral of PrEP among 30 of 1603 (1.9%) participants, of whom 2 (6.7%) were subsequently found to be acutely infected with HIV. Overall, the absolute risk of excess drug resistance during FTC/TDF PrEP was 0.05% (5/9222).
**Conclusions:** This analysis supports recent World Health Organization PrEP implementation guidance suggesting that rapid 3rd generation antibody tests are sufficient to minimize the overall risk of DR from PrEP. DR risk is higher with FTC/TDF PrEP compared with TDF PrEP. RNA testing before starting PrEP minimizes DR risk further while increasing costs and the risk of HIV infection due to delayed PrEP initiation.

## TUAC0105LB

### RESIDUAL DAPIVIRINE RING LEVELS INDICATE HIGHER ADHERENCE TO VAGINAL RING IS ASSOCIATED WITH HIV-1 PROTECTION

E. Brown[1,2], T. Palanee-Philips[3], M. Marzinke[4], C. Hendrix[4], C. Dezutti[5], L. Soto-Torres[6], J. Baeten[7]
*[1]Fred Hutchinson Cancer Research Center, Seattle, United States, [2]University of Washington, Seattle, United States, [3]University of the Witswaterand, Johannesburg, South Africa, [4]Johns Hopkins University, Baltimore, United States, [5]University of Pittsburgh, Pittsburgh, United States, [6]NIAID, Rockville, United States, [7]Univeristy of Washington, Seattle, United States*
*Presenting author email: erbrown@fredhutch.org*

**Background:** In MTN-020/ASPIRE, a vaginal ring containing dapivirine was found to decrease the risk of HIV-1 acquisition by 27% overall in an intention-to-treat analysis compared to placebo and by 37% in an analysis excluding data from two sites with lower adherence/retention. In subgroup analyses, no HIV-1 protection was seen in women ≤ age 21, for whom adherence appeared lower. In studies of tenofovir-based prophylaxis, objective markers of adherence have been important in understanding HIV-1 protection when products are used.
**Methods:** Rings were manufactured with 25 mg of dapivirine, and phase I studies indicated that ~4 mg of dapivirine on average are released during four weeks of continuous use; therefore, levels ≤22 mg were defined as having higher adherence for the present analysis. Starting one year into the trial, we tested the residual dapivirine levels (RDL) remaining in returned, used rings in ASPIRE. Visits at which participants did not return the ring, did not have access to the ring due to product hold or refusal or had RDL >22 mg were categorized as less or non-adherent. The association between HIV-1 acquisition and adherence was assessed using time-varying covariate Cox models adjusted for age and study site, including visits occurring at month 12 and beyond.
**Results:** Of the 2629 women enrolled in ASPIRE, 2359 were included in this analysis. Compared to placebo, higher adherence to the active dapivirine ring (i.e., RDL≤22 mg) was associated with a 65% (95% CI 23-84, p=0.009) reduction in HIV-1 risk. Results were similar for the full study population and when excluding the two sites with lower adherence/retention (risk reduction 67%, 95% CI 23-86), and point estimates suggested HIV-1 protection for both women >21 years (risk reduction 72%, 95% CI 21-90) and ≤21 years of age (risk reduction 50%, 95% CI -78-86). Partial/low adherence (i.e., RDL>22 mg) was not significantly associated with HIV-1 protection (relative risk reduction 35%, 95% CI -10-61, p=0.12).
**Conclusions:** Residual dapivirine levels in returned rings, an objective marker of adherence, indicate that higher adherence to the dapivirine vaginal ring may provide >65% protection from HIV-1 acquisition.

### STRENGTHENING HIV SURVEILLANCE IN THE ANTIRETROVIRAL THERAPY ERA: BASELINE FINDINGS OF HIV PREVALENCE AND INCIDENCE FROM KWAZULU-NATAL, SOUTH AFRICA

A. Kharsany[1], C. Cawood[2], D. Khanyile[2], A. Grobler[1], A. Puren[3], T. Kufa-Chakeza[3], N. Samsunder[1], J. Frohlich[1], Q. Abdool Karim[1], G. George[4], K. Govender[4], C. Toledo[5], Z. Chipeta[6], L. Zembe[6], M. Glenshaw[6], L. Madurai[7], A. Bere[6], V. Deyde[6]
*[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]Epicentre Risk Management, Cape Town, South Africa, [3]Centre for HIV and STIs, National Institute for Communicable Diseases, National Health Laboratory Service (NICD/NHLS), Johannesburg, South Africa, [4]Health Economics and HIV and AIDS Research Division (HEARD), University of KwaZulu-Natal, Durban, South Africa, [5]Centres for Disease Control and Prevention (CDC), Atlanta, United States, [6]Centres for Disease Control and Prevention (CDC), Pretoria, South Africa, [7]Global Clinical and Virology Laboratory, Durban, South Africa*
*Presenting author email: ayesha.kharsany@caprisa.org*

**Background:** South Africa has over 6,000,000 persons living with HIV/AIDS, and the province of KwaZulu-Natal (KZN) is severely affected. We report on baseline findings from the population based household survey from the uMgungundlovu district of KZN, South Africa.
**Methods:** A two-stage cluster-based sample of randomly selected EAs and households; enrolled one eligible individual 15-49 years per household (2014 to 2015).. Structured questionnaires were administered and peripheral blood samples collected for laboratory measurements. HIV incidence was measured using the HIV LAg-avidity assay, adjusting for ART use and viral load. Taking into account the sampling design and adjusting for non-response, weighted data were analysed using SAS survey procedures.
**Results:** Of the 14624 eligible households visited, 11299 participated and 9812 individuals were enrolled; 63.8% females and 36.2% males. Overall HIV prevalence was 36.3% (95%CI 34.8-37.8); 44.1% (95% CI 42.3-45.9) females and 28.0% (95% CI 25.9-30.1) males [Risk ratio 1.57, 95% CI: 1.45-1.71, p< 0.001]. Prevalence was higher in females compared to males, 15-19 years (11.5% vs 5.0%, p< 0.001) and 20-24 years (32.4% vs 10.1%, p< 0.001). Prevalence peaked at 66.4% in females 35-39 years compared to 59.6% in males 40-44 years. A higher proportion of males had detectable virus (66.1% males vs 53.4% females, p< 0.001), however, 83.3% of females 15-19 years; 81.4% and 89.9% of males 20-24 and 25-29 years respectively had detectable virus. Males had a higher median (IQR) log viral load (3.69 c/ml, IQR 0.3-4.66 vs 1.83 c/ml, IQR 0-4.1; p< 0.001), with no difference in males and females 15-19 years; (males 3.57c/ml, IQR 1.3-4.6 vs females 4.1 c/ml, IQR 2.2-4.5; p=0.451). Overall HIV incidence was 3.21/100person-years (PY), 95% CI 2.39-4.03; 4.06/100py, 95% CI 2.85-5.25 in females and 2.10/100py, 95% CI 1.13-3.05 in males.
**Conclusions:** Despite the scale up of HIV prevention and treatment programmes, HIV incidence remains unacceptably high in the rural sub-districts of KZN. The high incidence in women coupled with a higher proportion of HIV positive males having detectable virus at higher median c/ml has implications for sustained HIV transmission.

## TUAC0202

### SPATIAL ASSOCIATION BETWEEN POPULATION VIRAL LOAD AND HIV INCIDENCE

B. Riche[1], D. Maman[2], S. Wanjala[3], P. Mendiharat[4], W. Hennequin[3], A. Vandenbulcke[3], I. Mukui[5], F. Subtil[1], R. Ecochard[1]
*[1]Service de Biostatistique, Hospices Civils de Lyon, Lyon, France, [2]Epicentre - Médecins Sans Frontières (MSF), Clinical Research Department, Cape Town, South Africa, [3]Médecins Sans Frontières, Nairobi, Kenya, [4]Médecins Sans Frontières, Paris, France, [5]National AIDS and STDs Control Program, Nairobi, Kenya*
*Presenting author email: david.maman@epicentre.msf.org*

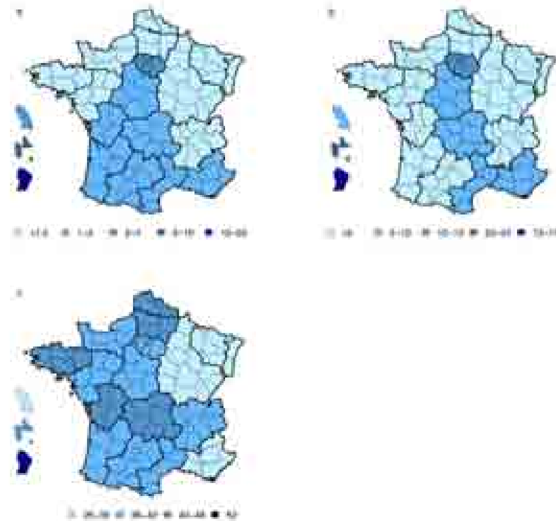
**Background:** Treatment as Prevention programs aim at reducing HIV incidence by increasing the proportion of HIV-positive individuals with undetectable Viral Load (VL) through ART roll-out. However, critical data on the relation between population VL and incidence are needed. We explored the spatial association between HIV incidence and population VL in a high HIV prevalence setting in western Kenya.
**Methods:** We conducted a population-based survey of persons aged 15-59 years in Ndhiwa sub-county, Nyanza, Kenya, collecting spatial (Cluster and Health Center location) and individual (including, HIV status, incidence and VL) information. Population VL is defined as the proportion of individuals HIV+ with a VL>1000cp/mL among the entire population. Population VL, HIV incidence and distance to the nearest health center (HC, delivering ART) were derived. A mixed Poisson regression model of incidence was used, adjusted on age (9 age groups), gender, distance to HC (3 classes) and population viral load in each cluster (6 classes).
**Results:** A total of 6,076 individuals from 165 clusters participated to the survey. HIV prevalence was 24.1% (95%CI 23.0-25.2). VL suppression among HIV-positive participants was 39.0% (95%CI 35.9-42.2). Among all participants, 13.7% (95%CI 12.9-14.6) were HIV-positive with a VL< 1,000 cp/mL. Incidence increased with population viral load and was 1.7, 3.3, 4.8 and 5.4 new cases per 100PY for a population VL of [5-10%[, [10-15%[, [15-20%[ and [20-25%[, respectively.
In the model, incidence was strongly associated with population VL. Relative risks were 1.26 (95% CI 0.6-2.6), 2.45 (95% CI 1.3-5.0), 3.40 (95% CI 1.8-7.0), 4.02 (95% CI 2.0-8.4) and 4.46 (95% CI 2.0-10.6) for a population VL of [5-10%[, [10-15%[, [15-20%[ and [20-25%[ compared to reference [0%-5%].
**Conclusions:** We found a strong association and gradient between HIV incidence and population HIV viral load. This association suggests that population-level reduction of HIV incidence could be achieved by reducing population viral load through ART roll-out in the general population.

## TUAC0203

### MAPPING THE HIV EPIDEMIC TO IMPROVE PREVENTION AND CARE: THE CASE OF FRANCE

L. Marty[1], F. Cazein[2], J. Pillonel[2], D. Costagliola[1], V. Supervie[1]
*[1]Institut National de la Santé et de la Recherche Médicale (INSERM), UMR S 1136, Paris, France, [2]INVS, Paris, France*
*Presenting author email: lise.marty@iplesp.upmc.fr*

**Background:** Despite decades of treatment efforts, in most settings, the number of new HIV infections remains unacceptably high and late HIV diagnosis remains common. To improve HIV prevention and care, a more focused response is needed using detailed data to map areas that are most impacted by HIV.
**Methods:** We used data on newly diagnosed HIV cases from 2004 to 2012 and a back-calculation model, previously developed (Ndawinz et al. AIDS 2011, Supervie et al. AIDS 2014), to estimate, in France, at the national level, at the regional level and by HIV exposure group, three epidemiological indicators: HIV incidence, distribution of times from HIV infection to diagnosis, and the number of undiagnosed HIV infections.
**Results:** We estimated that in 2012, around 6800 (95% confidence interval: 5900-7700) new HIV infections occurred in France, 24600 (21000-26000) individuals were living with undiagnosed HIV and the median time from infection to diagnosis was 36 months (inter-quartile range: 12-64). HIV incidence and median time from infection to diagnosis were stable since 2004. HIV incidence and undiagnosed HIV prevalence rates were highest in French Guiana, French Antilles, Paris region (p< 0.001; Figure 1a and b). Median time from infection to diagnosis was longest in French Guiana, Poitou-Charentes, Brittany, Limousin-Auvergne, Guadeloupe, Nord-Pas-de-Calais and Picardy (p< 0.001; Figure 1c). The epidemic was mainly driven by both MSM and born abroad heterosexuals in the Paris region, and by born abroad heterosexuals in French Guiana.
**Conclusions:** To the best of our knowledge, this is the first study that provides estimates of three main epidemiological indicators at a granular level, throughout the use of a detailed national dataset. These estimates will be essential to tailor and evaluate a more focused HIV response.



*[Estimates of: (a) HIV incidence rates per 10000; (b) Undiagnosed HIV prevalence rates per 10000; (c) Median time from infection to diagnosis (months)]*

## TUAC0204

### ONGOING HIGH HIV INCIDENCE AMONG WOMEN AND MEN IN CHÓKWÈ, SOUTHERN MOZAMBIQUE: A CALL FOR RAPID SCALE UP OF COMBINATION HIV PREVENTION

R. Nelson[1], R. Thompson[2], I. Casavant[3], S. Pals[1], J. Bonzela[2], D. Mugabe[2], J. Come[2], D. Ujamaa[1], J. Cardoso[4], A. Auld[1], B. Maculuve[5], S. Wei[3], D. Shodell[6], D. MacKellar[1]
*[1]Centers for Disease Control and Prevention, Atlanta, United States, [2]Chókwè Health Research and Training Center (CITSC), Chókwè, Mozambique, [3]Centers for Disease Control and Prevention, Maputo, Mozambique, [4]Jhpiego, Maputo, Mozambique, [5]Public Health Department Gaza, Xaixai, Mozambique, [6]Colorado Department of Public Health and Environment, Denver, United States*
*Presenting author email: rnelson1@cdc.gov*

**Background:** In 2012, estimated HIV incidence among sexually active women in Chókwè Mozambique was 4.6 per 100 person-years (PY). In 2014, the Chókwè Health Demographic Surveillance System (CHDSS) incorporated HIV testing and counseling (HTC) within annual rounds of demographic surveillance. In this abstract, we report HIV incidence during the first two rounds of CHDSS HTC.
**Methods:** CHDSS includes 95,589 residents in Chókwè town and 6 villages in Southern Mozambique. During each round, all CHDSS households are visited and HTC is offered to all encountered residents. Round 1 was conducted April 2014-May 2015; round 2 May-December 2015. Analyses are restricted to residents who tested HIV-negative in round 1 and retested in round 2. Adjusted incidence rates (IR) per 100 person-years were estimated with a generalized linear model using SAS 9.4.
**Results:** Of 20,235 participants aged 15-59 years who tested HIV-negative in round 1, 10,826 (54%) retested in round 2. HIV incidence was high overall (adjusted IR, 4.7) and higher among residents in Chókwè town than villages (p< 0.001). Among participants aged 15-24 years, incidence among females was higher than males (4.0 vs. 1.0; p< 0.001); among participants aged 25-44 years, incidence was higher among males than females (10.8 vs. 7.9; p=0.02). Incidence was not statistically significantly different between males and females 45-59 years of age (p=0.08).

| Demographic Group | Participants | Incident Infections | Follow-up Person Years | Crude IR per 100 Person Years | Adjusted IR per 100 Person Years |
|---|---|---|---|---|---|
| Total | 10826 | 473 | 8195.8 | 5.8 (5.3-6.3) | 4.7 (4.2-5.4) |
| Chokwe Town | 6670 | 329 | 4733.1 | 7.0 (6.2-7.7) | 6.0 (5.2-6.9) |
| Villages | 4152 | 144 | 3462.6 | 4.2 (3.5-4.9) | 3.4 (2.8-4.2) |

*[Adjusted HIV Incidence and 95% Confidence Intervals, Total and by Urbanicity]*

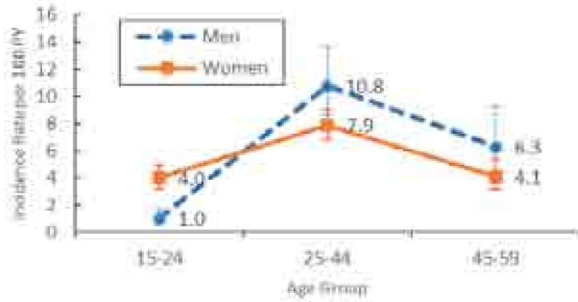
Late Breaker Posters
Author Index



*[Adjusted HIV Incidence and 95% Confidence Intervals, by Sex and Age-group]*

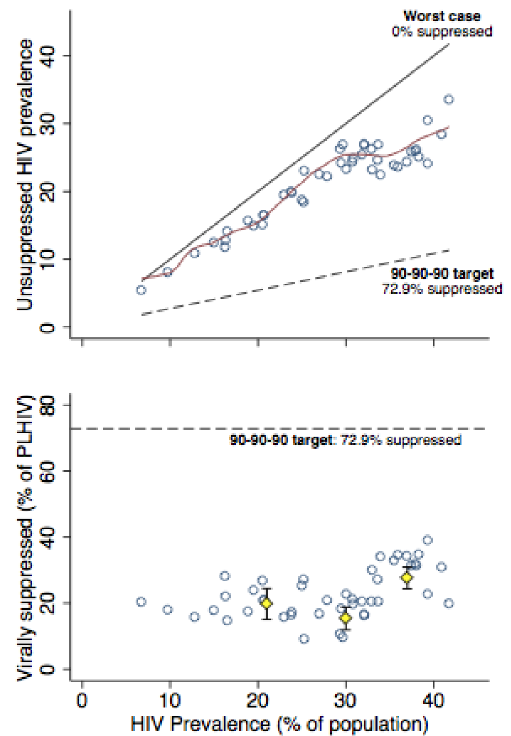
**Conclusions:** HIV incidence is exceptionally high among residents aged 25-44 years in Chókwè District. Among persons under 25 years, HIV incidence is higher in women than men; among older persons, incidence is higher in men. To reduce HIV incidence, combined evidence-based HIV prevention interventions such as HIV testing and linkage to care, antiretroviral treatment as prevention, and male circumcision should be scaled up in Chókwè district.

## TUAC0205

### DISTRICT PREVALENCE OF UNSUPPRESSED HIV IN SOUTH AFRICAN WOMEN: MONITORING PROGRAMME PERFORMANCE AND PROGRESS TOWARDS 90-90-90

J. Bor[1,2], A. Brennan[2,3], M.P. Fox[1,2,3], M. Maskew[2], W. Stevens[4], S. Carmona[4], W. MacLeod[1,2]
*[1]Boston University School of Public Health, Department of Global Health, Boston, United States, [2]University of Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [4]National Health Laboratory Service, Johannesburg, South Africa*
*Presenting author email: jbor@bu.edu*

**Background:** Population prevalence of unsuppressed HIV is a key determinant of HIV morbidity, mortality, and onward transmission, and can be reduced through both treatment and prevention strategies. We estimate unsuppressed HIV prevalence among reproductive-aged women in South Africa's 52 districts.
**Methods:** District HIV prevalence for women 15-49 years was estimated using national antenatal surveillance data, pooled for 2010-2012 to improve precision. Data were combined from District Health Information System (DHIS), National Health Laboratory Service (NHLS), and South African Census to estimate proportion virally suppressed. We multiplied total numbers of patients remaining on ART in 2012 (DHIS) by proportions of patients with viral loads in 2012 that were women 15-49 years and virally suppressed (NHLS). We divided by the district population of women 15-49 years (Census) to obtaining the population prevalence of suppressed HIV. Subtracting this number from antenatal prevalence, we obtained *prevalence of unsuppressed HIV*. We also computed the ratio of these quantities, *percent of HIV-infected who are virally suppressed*. We assessed the relationship between each of these measures and district HIV prevalence in linear regression.
**Results:** Prevalence of unsuppressed HIV varied widely across districts (5% to 33%, Fig 1a). By 2012, no district had achieved the 90x90x90 target of 72.9% population-level viral suppression in the study population of reproductive-aged women; however, there was large variability in the percent of HIV-infected who were virally suppressed (9% to 39%, Fig 1b) and thus clear opportunity to identify the determinants of high-performing districts. Districts with the highest viral suppression had the highest HIV prevalence (p < .001), suggesting successful targeting of resources, but also a need for renewed focus on districts in the second tier of HIV prevalence.
**Conclusions:** Unsuppressed HIV prevalence and percent suppressed among the HIV-infected offer measures of unmet need and program performance that can be estimated from routine programme and surveillance data.



*[Figure 1. Unsuppressed HIV prevalence and population viral suppression in South African districts]*

# TUAD01 PATHWAYS: MOVING FROM STRUCTURAL RISKS TO RESPONSES

## TUAD0101

### SOCIAL ECOLOGICAL CONTEXTS OF HIV VULNERABILITY AMONG INTERNALLY DISPLACED WOMEN IN LEOGANE, HAITI

C. Logie[1], C. Daniel[2], Y. Wang[3]
*[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]Adelphi University, Social Work, Long Island, United States, [3]University of Toronto, Toronto, Canada*

**Background:** The confluence of poverty, increased gender-based violence, and limited access to sexual health services elevate HIV infection risks among women displaced from natural disasters. Scant research has examined factors associated with condom use among internally displaced women in post-disaster settings, such as post-earthquake Haiti. Approximately 65,000 people continue to experience protracted displacement in Haiti where they face chronic poverty, overcrowding, and unsafe living conditions. We examined factors associated with consistent condom use among internally displaced women in Haiti.
**Methods:** This community-based study involved a cross-sectional survey with a peer-driven sample of internally displaced women in Leogane, Haiti. Peer health workers administered tablet-based structured interviews to internally displaced women (n=175). We conducted multivariate logistic regression analyses to assess correlates of past month condom use.
**Results:** The 128 participants who reported being sexually active in the past four weeks were included in analyses. Two-thirds (n=84; 65.2%) reported consistent condom use in the past month. Three-quarters (n=95; 74.2%) of participants ate one meal or less per day. In multivariate logistic regression analyses controlled for age and income, consistent condom use in the past month was associated with meals per day (AOR 2.02, p=0.022), sexual relationship power (AOR 1.12, p=0.006), no reported intimate partner violence (AOR 2.82, p=0.022), and poor self-rated health (AOR 3.25, p=0.040). Participants who were less likely to report consistent condom use in the past month reported sex work involvement (AOR 0.09, p=0.004), shorter relationship duration (AOR 0.18, p=0.004), depression (AOR 0.62, p< 0.001), and a higher number of sex partners in the past year (AOR 0.56, p< 0.001). This model explained 48.7% of the variation in consistent condom use scores (Pseudo $R^2$=0.487).
**Conclusions:** Findings provide the first assessment of contextual factors associated with condom use among internally displaced women in post-earthquake Haiti. This research highlights the salience of a social ecological approach to understanding

HIV vulnerability, underscoring intrapersonal (e.g. depression), interpersonal (e.g. relationship duration) and structural (e.g. food security, intimate partner violence) domains. Understanding social ecologies of HIV vulnerability among internally displaced women can inform complex, multi-level interventions that address food security, gender-based violence, and depression, to advance HIV prevention in post-disaster settings.

## TUAD0102

### STILL "AT RISK": AN EXAMINATION OF HOW STREET-INVOLVED YOUTH UNDERSTAND, EXPERIENCE, AND ENGAGE WITH "HARM REDUCTION" IN VANCOUVER'S INNER CITY

N. Bozinoff[1], D. Fast[1,2], C. Long[3], T. Kerr[1,2], W. Small[1,4]
*[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, St. Paul's Hospital, Department of Medicine, Vancouver, Canada, [3]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada, [4]Faculty of Health Sciences, Simon Fraser University, Burnaby, Canada*

**Background:** Vancouver is an international leader in implementing interventions to reduce harms related to injection drug use, including a large needle exchange program and North America's first government-sanctioned supervised injection facility. However, street-involved youth who use drugs continue to be vulnerable to HIV infection as a result of high rates of syringe sharing. In order to understand why youth in this setting continue to experience drug-related harms in the context of intensive public health intervention, we consider how these youth understand, experience and engage with harm reduction programs in the context of entrenched marginalization.
**Methods:** Twelve semi-structured interviews were conducted in 2013 with thirteen youth (ages 17-28) recruited from the At-Risk Youth Study, a prospective cohort of 500 street-involved and drug-using youth. These interviews were embedded within a larger, eight-year program of ethnographic research, and explored participants' understandings of "harm reduction" their use of specific services, and their ideas about improving their day-to-day lives. Interviews were transcribed verbatim and a thematic analysis was performed.
**Results:** Youth's understandings of and ideas about "harm reduction" were diverse, and went beyond public health efforts to minimize drug-related risks. Many youth articulated the limitations of existing programs, indicating that while they reduce the risk of HIV transmission, they offer little meaningful support to improve youth's broader life chances. Youth described how they used "softer drugs" like marijuana to reduce the amount or frequency of substances deemed more harmful (e.g. crack cocaine, heroin) to their mental and physical health. They also indicated that using "softer drugs" allowed them to transition from intravenous routes of administration to oral, inhaled or intranasal routes. Finally, youth indicated that spatial considerations (e.g., distance from Vancouver's Downtown Eastside) strongly determined access to harm reduction services, and to the more expansive visions of "wellness" that they envisioned for themselves.
**Conclusions:** In Vancouver, a large, well-established harm reduction infrastructure seeks to reduce drug-related harms such as HIV transmission among street entrenched youth. However, youth's multiple understandings, experiences and engagements with "harm reduction" in this setting illustrate the limitations of the existing infrastructure in improving their broader life chances, and addressing their desires for structural change.

## TUAD0103

### FORCED SEX, MIGRATION AND HIV INFECTION AMONG WOMEN FROM SUB-SAHARAN AFRICA LIVING IN FRANCE: RESULTS FROM THE ANRS PARCOURS STUDY

J. Pannetier[1], A. Ravalihasy[1], M. Le Guen[1,2], N. Lydié[3], R. Dray-Spira[4], N. Bajos[2], F. Lert[2], A. Desgress du Lou[1,5], Parcours Study Group
*[1]Université Paris Descartes-IRD, Centre Population et Développement, Paris, France, [2]INSERM, CESP-U 1018, Villejuif, France, [3]INPES, Saint-Denis, France, [4]INSERM, IPLESP UMRS 1136, Paris, France, [5]IRD, Paris, France*
*Presenting author email: julie.pannetier@ceped.org*

**Background:** In Europe, sub-Saharan African migrant women are a key population for HIV infection. Social hardships during migration may increase women vulnerability to sexual violence and HIV infection. The aim of this study is to assess the association between forced sex, migration and HIV infection among sub-Saharan African women living in France.
**Methods:** Parcours is a life-event survey conducted from February 2012 to May 2013 in health-care facilities in the Paris region, among two random samples of sub-Saharan migrant women: 570 receiving HIV care (156 acquired HIV in France) and 407 not diagnosed with HIV (reference group). Women were retrospectively asked whether they had ever been forced to have sex against their will and if happened, during which calendar year(s). Using mixed-effects logistic regression models, characteristics associated with an experience of forced sex after 14 years old in France, including migration history and living conditions each year after arrival in France, were first identified. Then, the frequency of forced sex after 14 years old in France was compared, adjusting for these characteristics, between women having acquired HIV either before or after migration and those HIV-uninfected.
**Results:** Overall, 22.2%, 23.1% and 18.3% of women HIV-infected before migration, HIV-infected after migration and HIV-uninfected, respectively, reported an experience of forced sex after 14 years old (childhood sexual abuse was about 4%), and, 3.8%, 17.3% and 4.2%, respectively, reported an experience of forced sex after arrival in France. Having migrated because of being threatened in the country of origin (aOR=5.96[1.57-22.61]) and absence of stable (aOR=4.64[1.69-12.79]) or own (aOR=2.72[1.13,6.53]) housing in France were associated with a higher frequency of forced sex in France. Adjusting for migration history and living conditions, the frequency of forced sex in France was higher among women having acquired HIV in France compared to those HIV-uninfected (aOR=4.97[1.63-15.12]), while no difference was found for those HIV-infected before migration (aOR=2.18[0.78-6.04]).
**Conclusions:** Among sub-Saharan African migrant women, HIV acquisition in France may be related to a context of sexual violence. Women whose migration was motivated by violence and those who experience social hardships in the host country are at high risk of sexual violence.

## TUAD0104

### WHOONGA: OFF-LABEL ANTIRETROVIRAL MEDICATION FOR RECREATIONAL SUBSTANCE USE AND PREDICTED IMPLICATIONS FOR PRE-EXPOSURE PROPHYLAXIS HIV PREVENTION IN SOUTH AFRICA

C. Kuo[1,2,3], D. Operario[1,3], J. Hoare[2], K. Underhill[4], D. Giovenco[1], M. Atujuna[2,5], C. Mathews[2,6], D. Stein[2], L. Brown[3,7]
*[1]Brown University, School of Public Health, Department of Behavioral and Social Sciences & Center for Alcohol and Addiction Studies, Providence, United States, [2]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [3]Lifespan/Tufts/Brown Center for AIDS Research, Providence, United States, [4]Yale University, Center for Interdisciplinary Research on AIDS and Yale Law School, New Haven, United States, [5]Desmond Tutu HIV Foundation, Cape Town, South Africa, [6]South African Medical Research Council, Health Systems Research Unit, Tygerberg, South Africa, [7]Alpert Medical School of Brown University, Department of Psychiatry and Human Behavior, Providence, United States*
*Presenting author email: caroline_kuo@brown.edu*

**Background:** "Whoonga" is a colloquial term describing an illicit drug allegedly comprised of antiretroviral medication used alone, or in combination with cannabis, methamphetamine, heroin, and other substances. Few studies characterize whoonga use among adolescents. Off-label use of antiretrovirals may diminish supply of antiretroviral treatment medication, and contribute to non-adherence, medication resistance, and an illicit drug epidemic.
**Methods:** Emergent data on whoonga was derived from two adolescent HIV prevention studies conducted from 2015-2016 in Cape Town, South Africa. The first study was a baseline survey from an ongoing intervention study of family adolescent HIV prevention with N=399 adolescents and parents (adolescents: 100% Black African, 56% female, M=14 years; parents 100% Black African, 96% female, M=40 years). Participants were recruited through house-to-house community sampling, and completed behavioral self-reports of whoonga use via a computerized mobile smartphone with audio computer-assisted self-interview software. The second study is an ongoing qualitative study of acceptability of HIV pre-exposure prophylaxis (PrEP) for adolescents involving focus groups and interviews with N=24 adolescents (M=100% Black African, 60% female, 16-17 years) and N=17 service providers. Adolescent participants were recruited using convenience sampling in community and clinic settings; service providers were recruited using respondent driven sampling. We conducted descriptive analysis of quantitative survey data using SPSS and thematic analysis of qualitative data using NVivo. Brown University and University of Cape Town provided ethical approvals.
**Results:** Nearly a fifth of adolescents reported whoonga use (3% used themselves, 14% knew someone who used). Administration included smoking (71%), snorting (15%), injecting (15%), ingesting (15%), and inserting (3%). Parents also reported whoonga use (4% used themselves, 7% knew someone who used). Administration included smoking (57%), ingesting (29%), and snorting (14%). Preliminary qualitative findings demonstrated clinicians knew of patient whoonga use and were concerned about how PrEP implementation would impact whoonga initiation and abuse. Adolescents used specific slang for individuals using whoonga and identified linkages between crime and whoonga abuse.
**Conclusions:** Whoonga use is an emerging prevention challenge. Future studies should characterize the prevalence, composition, social and behavioral correlates of whoonga use, and further explore how the use of whoonga may be affected by PrEP implementation.

## TUAD0105

### IMPACT OF A STRUCTURAL INTERVENTION TO ADDRESS ALCOHOL USE AMONG GAY BAR-PATRONS IN SAN FRANCISCO: THE PACE STUDY

J. Hecht[1], A. Plenty[2], J. Lin[1], E. Charlebois[2]
*[1]San Francisco AIDS Foundation, San Francisco, United States, [2]University of California, Center for AIDS Prevention Studies, San Francisco, United States*
*Presenting author email: jhecht@sfaf.org*

**Background:** Men who have sex with men (MSM) have high rates of binge drinking (>50% in San Francisco (SF)), which can lead to increased sexual risk and other negative health outcomes. Heavy alcohol use is a recognized driver of the HIV epidemic in SF and gay bars have been identified as important venues for interventions addressing alcohol-related HIV risk.
We sought to evaluate the impact on alcohol intake and blood alcohol concentration (BAC) of a pilot structural intervention to increase the availability of free water, coupled with messaging on pacing alcohol intake and normative feedback about blood alcohol concentration in a convenience sample of gay bars in San Francisco, CA., USA.
**Methods:** From January 2012 to August 2014, study participants (n=1293) were recruited among exiting patrons of 4 gay bars in SF (2 intervention bars and 2 control bars). Participants answered a brief survey regarding alcohol intake and sexual risk behaviors then completed a breathalyzer test to measure their BAC. Individuals' measured BAC was displayed graphically in relation to others exiting the bar. Alcohol intake and measured BAC of participants were compared at baseline and post-intervention between control and intervention bar patrons using Pearson $\chi^2$.
**Results:** No significant differences between intervention and control bars were found at baseline. Participants were 69% Caucasian, 11% Latino, 5% African-American, 7% API, 8% other race; mean age was 37.5 years. We found high levels of alcohol use and sexual risk across all participants (56% reported condomless sex with a potentially serodiscordant partner at last sex). Post-intervention there were significant differences on measures of alcohol consumption: 30% of intervention bar participants had BAC levels over the legal limit (.08g/dL) compared to 43% of control bar participants, p< .0001 and 78% of intervention bar participants were above the AUDIT-C cut-off for problematic drinking compared to 87% in control bars, p< .001.
**Conclusions:** It is feasible to partner with bar owners to implement a structural intervention to reduce BAC levels of customers. Increasing the availability of free water and alcohol intake pacing messaging in gay bars can decrease patron alcohol intake and may impact alcohol related sexual risks for HIV.

## TUAD0106LB

### *'SOMETIMES I FEEL LIKE THE OTHER LIFE ON HEROIN WAS BETTER':* TRANSITIONING EXPERIENCES OF METHADONE CLIENTS AND THE POTENTIAL IMPLICATIONS IN HIV PREVENTION CARE AND TREATMENT IN NAIROBI, KENYA

E. Igonya, J. Ndimbii, A. Guise, F. Owiti, T. Rhodes, S. Strathde
*University of Nairobi, Nairobi, Kenya*
*Presenting author email: igonyae@gmail.com*

**Background:** In 2014, Kenya realized the ability to integrate new perspective in drug policy by introducing methadone (MAT)treatment for opiate-dependent persons. More than 500 people who use opiates have been enrolled in methadone in Nairobi. The study explored issues around access to and life experiences/changes with methadone, HIV care and treatment, health care and social support systems.
**Methods:** In depth interviews were conducted with HIV positive and negative men (n= 8) and women (n=22) who were receiving methadone at a psychiatric hospital in Nairobi. Interviews were complimented by observations and informal conversations with clients within a community based drop-in centre as well as interviews with community stakeholders.
**Results:** While clients were pleased with life changes brought about by methadone, a majority of study participants reported struggling with the transition from heroin and other drugs to methadone. In their everyday life, the labelled 'MAT clients' they struggle with social efficacy of MAT, thus immediate normalization of socioeconomic as well as sexual and reproductive lives in society. This result in tension between a new life on MAT and an old life on heroin and other drugs. This tension deepen a feeling of being a neglected population and lead some to revert to the 'old life' of (injecting) using heroin, while others mix methadone with other drugs such as heroin. The temptations of the 'old life' are exacerbated by the availability of heroin and other drugs in their environs; expectations of MAT; continued relations with friends who still use heroin and other drugs; a lack of income or being unoccupied; low self esteem; and a lack of or limited social support. In addition, those HIV positive reported stigma from fellow MAT clients.
**Conclusions:** The pressures of transition from heroin use to methadone is reported by some clients as involving a series of tensions that may lead to continued drug use and sexual risk of HIV, which may complicate the potential for methadone to support HIV prevention and treatment goals. Responses to these tensions could include pyscho-social support and structural interventions to facilitate the transition to use of methadone.

# TUAD02 REALITY CHECK: THE INTERSECTIONS OF HIV, VIOLENCE AND TRAUMA

## TUAD0201

### MICRO-LEVEL SOCIAL AND STRUCTURAL SYNDEMIC OF HIV RISK AMONG NEPALESE FEMALE SEX WORKERS

K. Deuba[1,2], S. Anderson[3], A.M. Ekström[1], S.R. Pandey[4], R. Shrestha[5], D.K. Karki[6], G. Marrone[1]
*[1]Karolinska Institutet, Department of Public Health Sciences, Stockholm, Sweden, [2]Public Health and Environment Research Center, Kathmandu, Nepal, [3]Karolinska Institutet, Stockholm, Sweden, [4]FHI 360, Kathmandu, Nepal, [5]University of Bergen, Bergen, Norway, [6]Nobel College, Kathmandu, Nepal*
*Presenting author email: deuba4k@gmail.com*

**Background:** Sex workers face stigma, discrimination and violence across the globe and are almost 14 times more likely to be HIV infected than other women in low- and middle income countries. In Asia, condom campaigns at brothels have been effective in some settings, but for preventive interventions to be sustainable it is important to understand micro-level social and structural factors that enable sex workers to practice safer sexual behaviors. This study assesses the syndemic effects of micro-level social and structural factors of unprotected sex and the prevalence of HIV among female sex workers (FSW) in Nepal.
**Methods:** In this quantitative study, 610 FSW were recruited using two-stage cluster sampling between September 2012 and November 2012 from 22 Terai highway districts of Nepal. Rapid HIV tests and face-to-face interviews were conducted to collect biological and behavioral information. A count of physical (sexual violence), social (poor social support and condom negotiation skills) and economic (unsafe sex to make more money) factors that operate at the micro-level was calculated to test the additive relationship to unprotected sex. Unprotected sex was assessed with the following question: "The last time you had sex with your client, did he use a condom?". Point-biserial correlation was conducted to measure the size and significance of associations between each syndemic condition and unprotected sex. Statistically significant associations between independent variables and unprotected sex were computed using multivariable logistic regression.
**Results:** The HIV prevalence was 1% in this presumably representative and large sample of FSW in Nepal. The prevalence of unprotected sex with client was high (24%). For each additional adverse physical, social and economic condition, the likelihood of unprotected sex with clients increased substantially: 1 problem=2.2 adjusted odds ratio (AOR); 95% confidence interval (CI)=1.3-3.7; 2 problems=3.1 AOR; 95% CI=1.8-5.4; 3-5 problems=7.3 AOR; 95% CI=3.9-13.9.
**Conclusions:** Interactions between two or more adverse conditions linked to physical, social and economic environment increased the risk of unprotected sex among FSW. A more holistic approach, including efforts to improve condom negotiation skills and to address economic vulnerability and abuse, is required to address unprotected sex among FSW in Nepal.

## TUAD0202

### PHYSICAL AND SEXUAL VIOLENCE AGAINST FEMALE SEX WORKERS IN COTE D'IVOIRE: PREVALENCE, AND THE RELATIONSHIP BETWEEN VIOLENCE AND STRUCTURAL DETERMINANTS OF HIV

C. Lyons[1], D. Diouf[2], F. Drame[3], A. Kouamé[4], R. Ezouatchi[5], A. Bamba[2], M. Thiam[2], B. Liestman[6], S. Ketende[6], S. Baral[6]
*[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Enda Sante, Dakar, Senegal, [3]Gaston-Berger University, Saint-Louis, Senegal, [4]Programme National de Lutte contre le Sida, Ministère de la Santé et de la Lutte contre le Sida, Abidjan, Cote D'Ivoire, [5]Gaston Berger University, Abidjan, Cote D'Ivoire, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States*
*Presenting author email: clyons8@jhu.edu*

**Background:** The HIV epidemic disproportionately affects female sex workers (FSW). Violence has been identified as an important measure in understanding HIV amongst FSW, however, limited data exist regarding the experience of physical and sexual violence amongst FSW in Cote d'Ivoire. Characterizing the prevalence of physical and sexual violence, as well as the relationship with structural HIV-related

risks can inform the development and implementation of programs and policies addressing health and human rights amongst FSW.
**Methods:** FSW, 18 years or older were recruited through respondent driven sampling in Abidjan, Côte d'Ivoire. A total of 466 participants completed a socio-behavioral questionnaire. Prevalence estimates of physical and sexual violence were evaluated as both crude and RDS adjusted estimates. The relationships between protection, coercive sexual risk, economic work environment, and physical and sexual violence were analyzed using chi squared tests, and bivariate and multivariable logistic regression.
**Results:** The RDS-adjusted prevalence estimate of physical violence amongst FSW in Cote d'Ivoire is 60.6%, and sexual violence is 44.1%. Among the study sample, police refusal of protection was associated with increased experience of sexual violence (Odds Ratio [OR]: 3.14; adjusted Odds Ratio [aOR]: 1.71; 95%CI: 1.02, 4.89). Being blackmailed because of FSW status was associated with physical (OR: 2.27; aOR: 2.08; 95%CI: 1.07, 4.04) and sexual violence (OR: 2.92; aOR: 1.96; 95%CI: 1.17, 4.65).
**Conclusions:** Violence amongst FSW in Cote d'Ivoire is prevalent, and shown to be severe and reoccurring. High levels of violence perpetrated by clients, as well as low levels of reported protection highlights a need for improved work environments for FSW in Cote d'Ivoire. Considering the policy and risk environment in Cote d'Ivoire, targeting the macrostructure through improved work environment and increased protection may be an effective way to address the cascade of barriers in realizing health and human rights for FSW in Cote d'Ivoire.

## TUAD0203

### EXPERIENCES OF CHILDHOOD TRAUMA INCREASES HIV-RISK BEHAVIOURS IN YOUNG WOMEN AND MEN IN URBAN INFORMAL SETTLEMENTS IN SOUTH AFRICA

A. Gibbs[1], K. Dunkle[2], T. Khumalo[1], N. Ntini[1], L. Washington[3], N. Mbatha[3], E. Chirwa[2], S. Willan[2], Y. Sikweyiya[2], N. Jama-Shai[2], R. Jewkes[2]
*[1]Health Economics and HIV/AIDS Research Division, Durban, South Africa, [2]Gender and Health Research Unit, Medical Research Council, Pretoria, South Africa, [3]Project Empower, Durban, South Africa*
*Presenting author email: gibbs@ukzn.ac.za*

**Background:** Young adults in informal settlements experience high HIV-incidence. While childhood trauma is known to increase HIV risks factors including violence, multiple partnering and substance use in other settings, little is known about the impact of childhood trauma in informal settlements.
**Methods:** We drew on cross-sectional data from 320 women and 319 men aged 18 to 38 in informal settlements in Durban, South Africa comprising the control arm of a cluster randomised RCT. Questionnaires collected scores assessing childhood trauma before 18, including experiences of physical violence, sexual abuse, emotional violence and harsh parenting. Outcomes were HIV-risk factors assessed over the past 12m: three or more main partners, three or more causal partners, three or more once-off partners, IPV and non-partner sexual violence and problematic alcohol use. For each outcome we built (male/female) regression models controlling for clustering and potential confounding variables .
**Results:** Mean ages were 24.4 years for women and 23.4yrs for men. Before the age of 18, 76.2% of men and 71.3% of women reported witnessing or experiencing physical violence; 48.0% of men and 34.7% of women experienced sexual violence; and 62.1% of men and 56.9% of women experienced emotional violence.
For women increasing childhood traumas were associated with more once off sexual partners, experiencing IPV, non-partner sexual violence and problematic alcohol use.

| | Childhood Trauma Mean (CI95%) | | | |
|---|---|---|---|---|
| Past 12m outcomes | Yes | No | aOR (CI) | P-Value |
| 3 or more once-off sexual partners | 9.1(7.5-10.7) | 5.7(5.0-6.4) | 1.08(1.00-1.16) | p<0.05 |
| Experience of physical and/or sexual IPV | 7.2(6.5-8.0) | 4.6(3.8-5.4) | 1.08 (1.01-1.15) | p<0.05 |
| Experience of non-partner sexual violence | 9.3(8.1-10.5) | 4.9(4.3-5.4) | 1.13(1.06-1.21) | p<0.0001 |
| Problematic alcohol use | 9.4(7.9-10.9) | 5.4(4.8-5.9) | 1.07 (1.00-1.15) | p<0.05 |

*[Women: Childhood traumas associated with HIV-risks]*

For men, increasing childhood traumas were associated with more main, casual and once-off sexual partners and perpetrating IPV and non-partner sexual violence.

| | Childhood trauma mean (CI) | | | |
|---|---|---|---|---|
| Past 12m outcomes | Yes | No | aOR (CI) | p-values |
| 3 or more main sexual partners | 8.8(7.5-10.0) | 6.7(5.9-7.6) | 1.08(1.02-1.13) | P<0.01 |
| 3 or more casual sexual partners | 9.2(7.5-10.8) | 6.9(6.1-7.7) | 1.06 (1.00-1.11) | P<0.05 |
| 3 or more once-off sexual partners | 8.7(7.3-10.1) | 7.0(6.1-7.8) | 1.06 (1.00-1.11) | p<0.05 |
| Perpetrating any IPV | 9.3(8.3-10.2) | 5.1(4.2-6.0) | 1.14 (1.07-1.21) | p<0.0001 |
| Perpetrating non-partner sexual violence | 9.5(8.3-10.7) | 6.1(5.3-6.9) | 1.07 (1.02-1.13) | p<0.01 |

*[Men: Childhood traumas associated with HIV-risks]*

**Conclusions:** Experiences of childhood traumas were consistently associated with increased HIV-risk behaviours amongst young women and men in urban informal settlements, particularly number of recent sexual partners and experience/perpetration of IPV and non-partner sexual violence. Intervening with children and caregivers before 18 to reduce childhood trauma is critical for reducing future HIV-risk.

## TUAD0204

### HIV+ DIAGNOSES DURING PREGNANCY INCREASES RISK OF IPV POSTPARTUM AMONG WOMEN WITH NO HISTORY OF IPV IN THEIR RELATIONSHIP

A.K. Groves[1], H.L. McNaughton Reyes[2], D. Moodley[3], S. Maman[2]
*[1]American University, Sociology, Center on Health, Risk and Society, Princeton, United States, [2]University of North Carolina at Chapel Hill Gillings School of Global Public Health, Health Behavior, Chapel Hill, United States, [3]University of KwaZulu Natal, Nelson Mandela School of Medicine, Department of Obstetrics and Gynaecology, Durban, South Africa*
*Presenting author email: groves@american.edu*

**Background:** There have been mixed findings on the relationship between HIV and women's risk of IPV. Per the dual vulnerability model, it may be that HIV infection matters only for particular relationships. Specifically, when you add an HIV-positive diagnosis into an already stressed relationship (as indicated by IPV history) it may work synergistically to increase IPV risk. In contrast, women's relationships where there is no history of IPV may be more resilient to an HIV-positive diagnosis. Therefore, the aim is to test whether the positive association between HIV status and IPV will be exacerbated for women with a history of IPV.
**Methods:** Data come from 1064 women who participated in the baseline antenatal visit and 9-month postpartum follow up visit as part of a larger RCT. We conducted logistic regression analysis to examine our hypothesis. Model 1 assessed whether HIV diagnosis at baseline predicted physical IPV at follow up, controlling for demographic covariates. Model 2 included an interaction between HIV diagnosis and history of IPV.
**Results:** While HIV was not associated with postpartum IPV in the main effects model (AOR: 1.44, 95% CI: .78-1.97), there was a statistically significant interaction between HIV diagnosis and having a history of IPV (AOR: .40, 95% CI: .17-.96). The findings were in the opposite direction as expected: among women who had a history of IPV in the relationship, HIV status did not predict IPV postpartum (AOR: .87, 95% CI: .49-1.55). Yet among women who had no history of IPV in the relationship, receiving an HIV-positive diagnosis during pregnancy predicted postpartum IPV (AOR: 2.17, 95% CI: 1.06, 4.42).
**Conclusions:** Receiving an HIV-positive diagnosis in pregnancy did not exacerbate postpartum IPV for women with a history of IPV in their relationship; the diagnosis may not signify new stress within the relationship. However, the findings have important implications for women with no history of IPV. That is, women who test HIV-positive and have no history of IPV should be counseled regarding their future risk of IPV in their relationship. Given the negative health ramifications of IPV during the perinatal period for women and their children, IPV prevention interventions are needed.

### PHYSICAL ASSAULT PARTIALLY MEDIATES THE IMPACT OF TRANSGENDER STATUS ON DEPRESSION AND POLY-SUBSTANCE USE AMONG BLACK MSM AND BLACK TRANSGENDER WOMEN IN THE UNITED STATES: RESULTS FROM POWER

L. Bukowski, R. Coulter, N. Riley, S. Buehler, C. Hoffmann, A. Gehr-Seloover, R. Stall, The Power Study Team
*University of Pittsburgh, Graduate School of Public Health, Pittsburgh, United States*
*Presenting author email: lab108@pitt.edu*

**Background:** Black men who have sex with men (BMSM) and black transgender women (BTW) are vulnerable to physical assault, poly-substance use, and depression, outcomes that drive new HIV infections and poor HIV-related health outcomes in both populations. Though BTW are different than BMSM, no studies have examined how the manifestations of these outcomes may differ between populations. In order to fill this gap, we examined differences in physical assault, poly-substance use, and depression between BMSM and BTW, and we investigated whether physical assault mediates differences in poly-substance use and depression.
**Methods:** Cross-sectional data for our analysis came from the first two years of the ongoing study, *Promoting Our Worth, Equality, and Resilience* (POWER). In 2014 and 2015, POWER employed time-location sampling (TLS) to recruit a community-based sample of BMSM and BTW (n=3,426) who attended Black Pride events in six U.S. cities. Participants completed a behavioral health survey and were offered onsite HIV-testing. At total of 2,997 BMSM and 277 BTW (n=3,274), provided complete data for our analysis. All TLS weighted multivariable models controlled for age, education and city.
**Results:** BTW had significantly higher prevalence of physical assault than BMSM (44.8% vs 12.3%, respectively). In multivariable models, compared to BMSM, BTW had greater physical assault (AOR=5.2; 95% CI: 3.9, 7.0), poly-substance use (AOR=7.2; 95% CI: 4.9, 10.6), and depression (AOR=3.3; 95% CI: 2.5, 4.4). Physical assault attenuated the effects of transgender status on poly-substance use (AOR=3.9; 95% CI: 2.6, 5.9) and depression (AOR=2.4; 95% CI: 2.5, 4.4). The indirect effect of transgender status on poly-substance use via physical assault was 1.4 (95% CI: 1.2, 1.7), and the indirect effect of transgender status on depression via physical assault was 1.3 (95% CI: 1.15, 1.47). Physical assault partially mediated the relationships of transgender status with poly-substance use and depression.
**Conclusions:** BTW face an epidemic of physical assault. If this epidemic continues, efforts to address depression and poly-substance use as well as other downstream health outcomes (e.g. HIV incidence, HIV-related health outcomes) among BTW will be futile. Interventions addressing structural inequity are necessary to alleviate the instances of physical assault perpetrated against BTW.

### CHALLENGES TO ADVANCING HIV RESEARCH IN PREGNANCY: INSIGHTS FROM THE HIV RESEARCH COMMUNITY

R. Faden[1], S. Gilbert[1], K. Sullivan[2], J. Cadigan[2], C. Krubiner[1], E. Namey[3], M. Little[4], A. Lyerly[2], A. Mastroianni[5]
*[1]Johns Hopkins University, Berman Institute of Bioethics, Baltimore, United States, [2]University of North Carolina, Chapel Hill, School of Medicine, Chapel Hill, United States, [3]FHI 360, Durham, United States, [4]Georgetown University, Kennedy Institute of Ethics, Washington, United States, [5]University of Washington, School of Law, Seattle, United States*
*Presenting author email: sgilbert@jhu.edu*

**Background:** Concerns about including pregnant women in research have led to a dearth of evidence to guide safe and effective treatment and prevention of HIV in pregnancy. We aimed to identify the range of barriers to conducting research in this area.
**Methods:** We conducted a series of consultations with HIV investigators and clinicians to elicit their views and experiences conducting HIV research involving pregnant women. We solicited input from 55 colleagues in small groups or one-on-one sessions to discuss priorities and barriers to research with pregnant women. Content analysis was used to identify themes.
**Results:** Participants discussed a breadth of areas of needed research, including safety, efficacy and appropriate dosing of: newer ARVs for pregnant women; emerging preventive strategies; and treatment for HIV's co-infections, including but not limited to tuberculosis. Challenges to conducting research on pregnancy and HIV included regulatory and legal barriers, such as restrictive interpretations of current regulations; financial disincentives stemming from funders' views that pregnant women cost more to include and represent a small sub-population; social and cultural research norms, such as fear of reputational damage if harms arise for pregnant women or their fetuses; and logistical difficulties, such as challenges recruiting enough pregnant women to sufficiently power data analysis.

| Treatment | Co-infection & Co-Morbidities | Other/Cross-cutting |
|---|---|---|
| • Choice of ARV to optimize short and long term maternal health<br>• Optimal dosing throughout pregnancy<br>• Continuation of therapy after treatment for PMTCT | Safety and efficacy of treatment for HIV+ pregnant women with:<br>• TB and Malaria<br>• Opportunistic Infections<br>• Hepatitis B and C<br>• Hypertension, Eclampsia, Pre-Eclampsia<br>• Diabetes | • PK studies<br>• New Delivery Mechanisms (e.g., rings and patches)<br>• HIV & Fertility |
| **Prevention** | **Diagnostics** | **Vaccines** |
| • Chemoprevention (PrEP, Microbicides)<br>• Safe Conception | • Optimal HIV testing throughout pregnancy<br>• Resistance testing | • HIV Vaccine Trials<br>• Other Vaccine Trials with HIV-infected participants |

*[Table 1. Pressing research gaps relevant to pregnancy and HIV]*

| Ethical | Legal | Research Environment & Culture |
|---|---|---|
| • Calculating risk/benefit ratio<br>• Ensuring informed consent, including what role, if any, the biological father should have in decision making<br>• Burden on pregnant women of research study requirements | • Difficulty interpreting U.S. human subjects regulations related to pregnant women (what is „minimal risk" in clinical research?)<br>• Concerns about study disapproval by IRBs<br>• Studies with pregnant minors raise additional regulatory concerns<br>• Liability if study results in harm | • Reputational risk to the researcher if study results in fetal harm<br>• Belief that funders, regulators, and public would only view observational studies as ethical<br>• Easier to obtain funding and conduct research with other populations |
| **Financial** | **Analytical** | **Logistical** |
| • Required follow-up and potential ancillary care for women who become pregnant on study are costly<br>• Pharma does not perceive pregnant women as a lucrative market segment (little incentive to study with potential liability as a disincentive)<br>• Funders fail to prioritize research on pregnancy | • Data from pregnant women or women who become pregnant during study must be analyzed separately<br>• Low statistical power due to likely small sample size | • Most trials do not enroll pregnant women and require women who become pregnant to withdraw, so even conducting opportunistic or observational studies is difficult<br>• Need for „buy-in" from men for studies in many international settings<br>• Locating participants for data collection at fixed time points in pregnancy |

*[Table 2. Barriers to conducting clinical research relevant to pregnancy and HIV]*

**Conclusions:** Despite broad recognition of research gaps related to HIV and pregnancy, investigators face numerous challenges to advancing needed research. Clearer guidance for navigating the complex legal, regulatory and ethical landscape is needed to advance women's health at the intersection of pregnancy and HIV.

## TUAD0302

### FUTURE PREGNANCY INTENTIONS AND KNOWLEDGE OF METHODS FOR SAFER CONCEPTION AMONG FEMALE SEX WORKERS IN PORT ELIZABETH, SOUTH AFRICA

A. Rao[1], S. Baral[1], N. Phaswana-Mafuya[2], A. Lambert[3], Z. Kose[2], M. Mcingana[3], C. Holland[1], S. Ketende[1], S. Schwartz[1]
*[1]Johns Hopkins University, Epidemiology, Baltimore, United States, [2]Human Sciences Research Council, Port Elizabeth, South Africa, [3]TB/HIV Care Association, Port Elizabeth, South Africa*
*Presenting author email: arao24@jhu.edu*

**Background:** Female sex workers (FSW) are disproportionately affected by HIV and experience high rates of pregnancy. The objective of these analyses is to assess fertility intentions and the impact of HIV on pregnancy intentions and safer conception knowledge among FSW in Port Elizabeth, South Africa.
**Methods:** FSW in Port Elizabeth were recruited into a cross-sectional study using respondent-driven sampling. Participants completed an interviewer-administered questionnaire asking about future fertility intentions and were provided HIV testing and counseling. Robust Poisson regression was used to model adjusted prevalence ratios (aPrR) for correlates of positive fertility intentions among FSW < 45 years. Knowledge of safer conception methods was described using Fisher's-exact tests.
**Results:** Overall 391 FSW were represented in the analyses. Just over 50% (203/391) had received a prior HIV diagnosis and an additional 12% (46/391) were diagnosed

with HIV during the study. Slightly under half of FSW (185/391) reported future pregnancy intentions (47%). In bivariate analyses, knowledge of prior HIV diagnosis was negatively associated with pregnancy intentions as compared to HIV-negative women [PrR=0.68,95%CI (0.55-0.85)]. Older age, greater number of children living, and more years selling sex were also significantly negatively associated with pregnancy intentions. Being in a relationship was significantly positively associated with pregnancy intentions. In multivariate analyses, only parity remained significantly associated with future pregnancy intentions. Knowledge of safer conception methods, such as timed condomless sex, pre-exposure prophylaxis, or self-insemination was low and non-statistically-significantly different between those with and without pregnancy plans (Table 1).

**Conclusions:** Pregnancy intentions were high and not independently associated with HIV status. Moreover, there was limited knowledge of safer conception methods suggesting the need for specific advice for FSW on how to conceive safely given that most women were living with HIV and have specific sexual risks of HIV acquisition and transmission given their occupation.

### "I GOT TESTED SO I COULD NOT LOSE HIM": HIV TESTING PRACTICES AND SUBSEQUENT SEXUAL BEHAVIOURS OF SEX WORKERS AND CLIENTS IN MOMBASA, KENYA

T.B. Masvawure[1,2], Y. Lafort[3], S. Chabeda[4], A. Restar[5], P. Gichangi[4], J. Tocco[1], T. Sandfort[1], J. Mantell[1]
*[1]New York State Psychiatry Institute (NYSPI), HIV Center for Clinical and Behavioral Studies, New York, United States, [2]College of the Holy Cross, Sociology and Anthropology, Worcester, United States, [3]Ghent University, Gent, Belgium, [4]International Centre for Reproductive Health, Mombasa, Kenya, [5]Columbia University, Mailman School of Public Health, New York, United States*
*Presenting author email: tmasvaure@yahoo.com*

**Background:** HIV testing is a critical step toward accessing treatment for individuals who test positive, but there is no consensus over whether knowing one's HIV status leads to less—or more—sexual-risk taking for individuals who test HIV-negative. We examined the HIV testing practices of female and male sex workers (FSWs, MSWs) and clients in Mombasa and how HIV testing relates to their subsequent sexual behaviors.

**Methods:** We conducted 75 semi-structured interviews with sex workers and clients recruited from 18 bars/nightclubs in Mombasa to guide intervention development. Eligibility criteria were being ≥18 years, regular patron of venue, solicited vaginal/anal intercourse with sex worker/client at that venue in last 3 months, willingness to be audio-recorded, and being visibly sober.

**Results:** Most participants had tested for HIV in the previous 12 months. HIV testing was more common among sex workers than clients, with some testing three times a year. HIV testing was undertaken both as a *response to* and as a *reason* for engaging in condomless sex. For instance, participants sought HIV testing following a high-risk sexual encounter, such as after condomless sex, condom breakage with commercial sex partners, or after a sexually transmitted infection. Some sex workers and clients, however, reported getting tested in order to engage in condomless vaginal and anal sex with main *and* regular commercial sex partners, particularly those with whom condom use was difficult to realize. Knowing a partner's HIV status or testing with a partner were frequently given as explanations for not using condoms with these partners. Many FSWs tested on the same or next day after they engaged in high-risk sex so that they could get post-exposure prophylaxis. Other participants sought testing weeks or months later.

**Conclusions:** HIV testing is used by some sex workers and clients as a reason to engage in condomless sex with commercial partners. However, given the high HIV risk involved in sex work, HIV prevention programs should continue to underscore the importance of both HIV testing and consistent condom use in these encounters.

## TUAD0304

### BEHIND CLOSED DOORS: SEX, REPRODUCTION AND THE HOUSEHOLD SPACE IN RURAL SOUTH-WESTERN UGANDA

A. Tam[1], G. Tumwekwase[2], E. Kabunga[2], S. Russell[1], J. Seeley[2,3]
*[1]University of East Anglia, School of International Development, Norwich, United Kingdom, [2]MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom*
*Presenting author email: a.tam@uea.ac.uk*

**Background:** In south-western Uganda HIV prevalence and total fertility rates are high amongst married individuals. Sex and reproduction in marriage primarily takes place in the home. This space is associated with privacy and preconceived ideas of gender norms, which can pose challenges to the negotiation and management of sexual and reproductive health (SRH) behaviours. This study set out to understand the challenges, risk perceptions and strategies used by men and women at different stages of the life-course to manage and negotiate conflicting SRH issues in marriage.

**Methods:** Data collection took place over 12 months within an existing general population cohort in rural south-western Uganda. Methods included life-story interviews and focus groups with individuals who had ever been married. Participants were randomly selected from six villages, where HIV prevalence ranges between 4.5%-16%. In-depth interviews were also conducted with religious leaders, traditional healers and health workers. Iterative thematic analysis was used to interpret, code and organise the data.

**Results:** Developing the home, unprotected sex and having children are central to the marital relationship in this setting. Failure to fulfil cultural expectations of gender roles and SRH behaviours within the household space were associated with marital dissatisfaction, relationship instability and extra-marital relations. This paper focuses on the SRH strategies described by men and women at different stages of marriage and the life-course. Strategies include: claiming space and time for sexual intimacy, techniques for managing menstruation, hygiene practices, and the various methods used to achieve fertility preferences and resolve SRH problems.

**Conclusions:** Individuals in marital relationships face specific challenges in managing SRH risks due demands in fulfilling gender roles, maintaining the marital relationship and stability of the home, whilst also achieving sexual desires and fertility preferences. Understanding the context and cultural meanings of sex and reproduction can facilitate tailored SRH intervention with married individuals.

### YOUTH SEXUAL AND REPRODUCTIVE HEALTH IN CHINA: RESULTS FROM A NATIONAL SURVEY OF 18,000 CHINESE COLLEGE STUDENTS

C. Li[1], Y. Zhao[2], H. Zhang[1], Z. Cheng[3], P. Hong[4], X. Liang[4], J. Gaoshan[5], L. Li[4], K. Tang[6]
*[1]Peking University, School of Public Health, Beijing, China, [2]Peking University, Institute for Medical Humanities, Beijing, China, [3]Peking University Health Science Center, Beijing, China, [4]China Family Planning Association, Beijing, China, [5]United Nations Population Fund (UNFPA), Beijing, China, [6]Peking University, Department of Global Health, Beijing, China*
*Presenting author email: lichunyan@pku.edu.cn*

**Background:** Notwithstanding years of efforts guided by *the National Strategy on HIV/ADIS Prevention and Control in Schools*, a climbing trend of HIV infections among college students has been observed in China[1]. This study investigated the status quo of HIV knowledge and sexual behavior patterns among college students, aiming to provide evidence for policy makers to identify priority areas of HIV/AIDS prevention and control[1] Ministry of Education. (2015). Retrieved from: http://www.moh.gov.cn/jkj/s3585/201508/e4c8a1e6809c4a8e9c49f7f8708873d1.shtml

**Methods:** This study was conducted from January to August in 2015 through a multi-stage sampling approach. 130 colleges were selected from eastern, central and western China. The internet-based survey questionnaire was subsequently delivered to the focal points in each school for voluntary participation Logistic and

linear regression were used to explore the association between risk factors and attitude/behavioral outcomes, under SAS 9.2 with a significant level of 0.05.

**Results:** 17966 students were included, of which 90% came from the 130 schools. 94.8% of the surveyed population responded. Only 55.6% of the students had received sexual education from school. 20.3% of the respondents didn't know that HIV could not be spread by sharing eating utensils. 47.0% in homosexual group had sex before (19.3% for heterosexual, 30.1% for bisexual). The proportion of condom use during the last sexual intercourse was 62.5%. 22.7% reported to have STI-related symptoms. Logistic regression results indicated that knowledge about sexual and reproductive health, family structures and sexual orientation were strongly associated with high-risk sexual behaviors, while gender, parents' education, stratifications of residential area and types of degree programs were significant effect modifiers for knowledge on HIV/AIDS related information.

**Conclusions:** High prevalence of risk sexual behaviors suggested that students remain a vulnerable population in terms of HIV/AIDS and STIs, especially among sexual minority groups. Future school-based interventions should be designed with a more gender-sensitive and individualized approaches.

## TUAD04 SHAME-LESS: STIGMA INTERVENTIONS THAT WORK

### TUAD0401

### "WE TALK, WE DO NOT HAVE SHAME": REDUCING HIV AND SEX WORK STIGMA THROUGH SOCIAL COHESION AMONG FSW LIVING WITH HIV IN THE DOMINICAN REPUBLIC

M.A. Carrasco[1], C. Kennedy[1], C. Barrington[2], M. Perez[3], Y. Donastorg[3], D. Kerrigan[1]
*[1]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [2]University of North Carolina Gillings School of Global Public Health, Department of Health Behavior, Chapel Hill, United States, [3]Instituto Dermatalogico y Cirugia de Piel Dr. Humberto Bogart Diaz, HIV Vaccine Research Unit, Santo Domingo, Dominican Republic*
*Presenting author email: s892@hotmail.com*

**Background:** Layered HIV and sex work stigma pose a significant barrier for female sex workers (FSW) living with HIV to engage in HIV prevention behaviors and access HIV treatment and care. How FSW manage and address layered stigma is not well understood. We explore the experiences of layered stigma among participants in *Abriendo Puertas*, a multi-level HIV/STI prevention, treatment, and care intervention for FSW living with HIV in Santo Domingo, Dominican Republic. Additionally, we examined social cohesion as a key community-driven strategy to address HIV and sex work stigma.

**Methods:** Using purposeful sampling, we conducted 23 in-depth interviews and two focus groups (n=11) with FSW living with HIV participating in the *Abriendo Puertas* intervention. Transcripts were analyzed using thematic analysis. First, constructs related to Foucault's conceptualization of power and discipline were identified. Then, transcripts were analyzed to identify individual and community narratives resisting and subverting stigma and shame.

**Results:** According to Foucault modern power is productive, giving life to those who adhere to social norms while disallowing it from those who transgress them through various forms of social disciplining. Foucault also proposed that such disciplining is often internalized leading to self-disciplining. We found that FSW living with HIV experience various instances of societal disciplining including domestic violence, verbal abuse, social rejection, and employer discrimination. They also experience self-disciplining in the form of hopelessness, low self-esteem, and loss of the will to live. The enhancement of social cohesion through participation in *Abriendo Puertas* was experienced as a means to subvert oppressive social norms around sexuality and healthism. This was verbalized as regaining hope and improving self efficacy, self-esteem, access to social support, and motivation to adhere to HIV treatment. Indeed, social cohesion provided the psychosocial space to reconstruct identity in more positive terms than those afforded by society. This was done through the production, repetition, and performance of de-stigmatized narratives in a safe space.

**Conclusions:** Findings indicate the importance of social cohesion as a means to challenge oppressive social norms and reduce layered stigma. HIV prevention, treatment, and care interventions for FSW living with HIV should include components to enhance social cohesion.

### TUAD0402

### EFFECTS OF A BRIEF AFFIRMATION INTERVENTION ON HIV-RELATED DISTRESS AND POSITIVE LIVING INTENTIONS AMONG INDIVIDUALS RECENTLY DIAGNOSED WITH HIV IN LESOTHO

K. Hartson[1], D. Sherman[2], S. Mofelehetsi[3], T. Ncheke[3], M. Khasoane[3]
*[1]University of California, San Francisco, Center for AIDS Prevention Studies, Department of Medicine, San Francisco, United States, [2]University of California, Santa Barbara, Department of Psychological and Brain Sciences, Santa Barbara, United States, [3]LENASO, Maseru, Lesotho*
*Presenting author email: kimberly.hartson@ucsf.edu*

**Background:** In addition to the physical burden of the illness, HIV also carries a psychological burden as those recently diagnosed with HIV navigate identity-related concerns including fears regarding how to live a normal life with HIV, possible stigmatization, and whether to disclose one's HIV status. This study investigated using a novel psychological intervention to reduce the psychological distress associated with being HIV positive and in turn, improve intentions to live positively.

**Methods:** 331 participants (207 women, mean age of 41) were recruited, following HIV diagnosis, from 10 clinics and hospitals in the Maseru and Leribe districts of Lesotho. Participants were randomly assigned to either the affirmation intervention condition or the control condition. Those in the affirmation intervention condition completed a brief, 10-minute exercise where they reflected on important values before receiving positive living counseling. Those in the control condition simply received positive living counseling without completing the affirmation task. Following the counseling sessions, all participants completed measures of their current HIV-related stress and distress and their intentions to engage in positive living behaviors. The impact of the affirmation intervention on participants' HIV-related distress and positive living intentions was evaluated by separate one-way analyses of variance.

**Results:** Overall, participants in the affirmation condition reported less HIV-related distress relative to those in the control condition. More specifically, participants in the affirmation condition reported experiencing significantly less stress ($M$=1.79 vs. $M$=2.17, $p$=.006), fewer intrusive HIV-related thoughts ($M$=2.17 vs. $M$=2.62, $p$=.011), fewer distressing emotions in response to HIV ($M$=1.27 vs. $M$=1.46, $p$=.027), and were less worried about dying from HIV ($M$=1.86 vs. $M$=2.31, $p$=.012). Additionally, those in the affirmation condition also reported greater positive living intentions including intentions to use condoms ($M$=5.56 vs. $M$=5.38, $p$=.046) and to take medications properly ($M$=5.53 vs. $M$=5.30, $p$=.029). Finally, the effect of the affirmation intervention on participants' intention to live positively was mediated by the extent to which the intervention reduced participants' HIV-related stress.

**Conclusions:** These findings provide initial evidence in support of using brief affirmation interventions in clinical settings to reduce the stress associated with HIV diagnosis and to improve openness to positive living health messages.

### "HAPPY IN MY OWN SKIN": IMPACT OF ANTI-STIGMA INTERVENTIONS ON PEOPLE LIVING WITH HIV IN TORONTO, CANADA

J.P.-H. Wong[1,2], K. Fung[3,4], S.S.C. Hui[5], H. Luyombya[6], A. Bisignano[6], D. Maitland[6], K. Poon[6], A.T.-W. Li[6,7]
*[1]Ryerson University, Daphne Cockwell School of Nursing, Toronto, Canada, [2]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [3]University of Toronto, Toronto, Canada, [4]University Health Network, Toronto, Canada, [5]Asian Community AIDS Services, Community Engagement & Ontario Positive Asians (OPA+) Coordinator, Toronto, Canada, [6]Committee for Accessible AIDS Treatment, Toronto, Canada, [7]Regent Park Community Health Centre, Toronto, Canada*
*Presenting author email: achui108@gmail.com*

**Background:** HIV stigma negatively affects the physical and psychological wellbeing of people living with HIV (PLHIV). While many stigma interventions have been carried out worldwide, few focused on both individual and collective empowerment. Community Champions HIV Advocates Mobilization Project (CHAMP) is an intervention study undertaken to mobilize PLHIV and non-PLHIV community leaders in HIV championship in the African, Caribbean, Asian, and Latino communities in Toronto, Canada.

**Methods:** CHAMP tested two anti-stigma interventions: Acceptance and Commitment Training (ACT) that enhances psychological flexibility, and Social Justice Capacity Building (SJCB) that promotes collective empowerment. Participants were randomly assigned to take part in two intervention arms: SJCB only, or ACT plus SJCB. We used focus groups and validated scales to collect data before, immediately after, and 9-month after the interventions. In addition, monthly activity logs were used to capture participants' post-intervention HIV and social justice championship activities.
**Results:** A total of 31 non-PLHIV and 35 PLHIV participated in CHAMP. Study results showed significant reduction in felt and enacted stigma in all intervention groups. This paper reports specifically on the impact of CHAMP interventions on PLHIV. Participants reported more self-acceptance; less felt stigma; improved psychological wellbeing; new confidence to speak out against HIV stigma and social injustices; and having stronger social connections. Many had disclosed their HIV status to family and friends, and to leaders at church, college and community. Some took action to pursue their life goals. In addition, PLHIV participants collectively reported a total of 575 activities undertaken at personal, family, organizational, and community levels. These activities included: advocating for social justice (n=102); support for PLHIV (n=55); HIV education (n=59); addressing HIV stigma (n=109); community building (n=101); and collective empowerment (n=149). After CHAMP, they have initiated and carried out four participant-driven championship projects.
**Conclusions:** CHAMP demonstrated that the combined use of psychological and empowerment interventions are powerful in reducing stigma. ACT supported individual empowerment by addressing felt stigma and enhancing self-acceptance; SJCB enabled PLHIV to locate their experience of stigma and discrimination in a collective context and build alliances for change. Coordinated efforts to scale up these interventions will contribute to effective HIV response and PLHIV empowerment.

### HIV vulnerabilities, gender affirmation and social resilience among transgender women in Lima, Peru: a community-based approach to HIV prevention, care and treatment

A. Perez-Brumer[1], S. McLean[2], A. Silva-Santisteban[3], L. Huerta[4], R. de la Grecca[4], K.H. Mayer[2], J. Sanchez[4,5], J.R. Lama[4,5], S.L. Reisner[2,6,7]
*[1]Columbia University, Mailman School of Public Health, New York, United States, [2]The Fenway Institute, Fenway Health, Boston, United States, [3]Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Asociación Civil Impacta Salud y Educación, Lima, Peru, [5]University of Washington, Department of Global Health, Seattle, United States, [6]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [7]Boston Children's Hospital and Harvard Medical School, Boston, United States*
*Presenting author email: aperezbrumer@gmail.com*

**Background:** TW experience unique vulnerabilities for HIV due to factors that limit access to and quality of services across HIV prevention, treatment, and care. Yet, social determinants of HIV disparities remain inadequately understood. Using a strengths-based framework, we assessed HIV vulnerabilities and community-level resilience strategies that buffer against marginalization and oppression, and harness existing supports to link TW to needed HIV-related services in Peru.
**Methods:** Between January-February 2015, 48 TW participated in a mixed-methods study including focus group discussion and brief survey. Audio files were transcribed verbatim and analyzed using an immersion crystallization approach to identify themes and relationships between themes. Descriptive analyses of survey data were conducted in Stata 13 and qualitative coding using Dedoose Version 6.1.18 (2015).
**Results:** Among TW (mean age of 29 years) 29% were unsure of their HIV status, over 60% reported sex work as primary income, and 48% reported having ever been arrested. Reported HIV vulnerabilities included: economic (occupation, cost of treatment), social (exclusion, recognition, support), and policy (legal protections, national guidelines). Themes of economic marginalization, multilevel stigma, and social recognition of gender identity emerged as salient across vulnerability groupings. Over half (52%) expressed distrust of healthcare providers and 62% postponed care due to perceived transgender-related stigma. Half reported experiences of discrimination within healthcare settings (e.g., incorrect pronoun, legal versus preferred name). To circumnavigate HIV-service barriers, social resilience strategies emerged within HIV vulnerability domains
(e.g., seeking healthcare in groups, using peer health promoters, vetting providers/clinics within social networks). Hormones were critical to affirming gender identity and being socially recognized; however, medical supervision of hormones was rare. Body modification was primarily self- or peer-administered, highlighting the importance of social networks to acquire desired and needed health-related resources and dissemination of peer-to-peer knowledge.
**Conclusions:** At the intersection of HIV vulnerabilities and collective agency, social resilience emerges as a strategy used by TW to access needed healthcare services in Peru. Fostering TW solidarity is a key component to ensure acceptability and sustainability of gender-affirming HIV interventions. Cross-sex hormone therapy alongside HIV services, peer support, and education represents a community-based, gender-affirmative approach to caring for TW in Peru.

## TUAD0405

### Changing forms of HIV stigma along the HIV care and treatment cascade: findings from a multisite qualitative study in Eastern and Southern Africa

O. Bonnington[1], J. Wamoyi[2], W. Ddaaki[3], D. Bukenya[4], F. Odongo[5], M. Skovdal[6], E. McLean[7], C. Nyamukapa[8], M. Moshabela[9], A. Wringe[1]
*[1]London School of Hygiene & Tropical Medicine, Epidemiology & Population Health, London, United Kingdom, [2]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [3]Rakai Health Sciences Program, Rakai, Uganda, [4]Medical Research Council, Uganda Virus Research Institute, Entebbe, Uganda, [5]Kenya Medical Research Institute, Kisumu, Kenya, [6]University of Copenhagen, Copenhagen, Denmark, [7]London School of Hygiene & Tropical Medicine, Karonga, Malawi, [8]Manicaland Centre for Public Health, Manicaland, Zimbabwe, [9]Africa Centre for Population Health, Mtubatuba, South Africa*
*Presenting author email: jwamoyi@hotmail.com*

**Background:** Despite expanding coverage of HIV care and treatment services, stigma remains pervasive for people living with HIV (PLHIV) in sub-Saharan Africa, undermining engagement in care. We aimed to explore the manifestation of stigma and discrimination at different stages of the HIV care cascade in seven health and demographic surveillance sites (HDSS) in Eastern and Southern Africa.
**Methods:** Between 2015-2016 we conducted 35 in-depth interviews per site in Uganda, South Africa, Tanzania, Kenya, Malawi and Zimbabwe with
(1) PLHIV purposively sampled from HIV clinics and HDSS databases linked to HIV clinic records,
(2) health providers and
(3) family members of people known to have died from HIV.
Topic guides explored patient and provider experiences of HIV testing, care and treatment services. Data were analysed thematically, aided by NVivo 10 software.
**Results:** Across all sites, anticipated stigma and discrimination were experienced at different points throughout the cascade. Poor privacy in some HIV testing facilities gave rise to concerns about confidentiality and subsequently fear of stigma. Additionally, powerlessness and coercion within patient-provider relationships often marked the initial cascade stages. To avoid being identified and stigmatised, patients sometimes changed their names when presenting at clinics, posing problems with monitoring of patients for better health outcomes. Non-integrated HIV services sometimes served to exacerbate 'othering' of patients, while in settings where services were supposedly integrated PLHIV were kept in separate waiting areas, accentuating their differences negatively. Women in PMTCT programmes often feared being questioned about absent partners, and "encouragement" of couple-testing resulted in some people shying away from testing, as did fear of being seen accessing the services by community members. Moreover, many PLHIV took medication in secrecy for fear of exposing their status to partners and others.
**Conclusions:** Despite efforts to improve HIV care services, stigma remains pervasive across the HIV cascade in all of these sites, though it often manifests in different forms. Context-specific interventions are needed to address stigma and discrimination of PLHIV within the community and in health services, and greater reflection is required to ensure policies aiming to expand HIV treatment do not exacerbate stigma and result in negative HIV outcomes.

# TUAE01 Healthy mothers, healthy babies: the path to eMTCT

## TUAE0101

### An inferential analysis of the impact of exposure to a peer mentor mother model on uptake of PMTCT services and maternal behavioural outcomes

S. Chapman, N. Kayuni Chihana, E. Scheepers, K. Schmitz
*mothers2mothers, Department of Programs and Technical Support, Cape Town, South Africa*
*Presenting author email: s.kaschula@gmail.com*

**Background:** For nearly 15 years, mothers2mothers (m2m) has trained facility-based lay health workers in implementing a peer-to-peer "Mentor Mother" (MM) Model to support Prevention of Mother-to-Child Transmission (PMTCT) in sub-Saharan Africa. In 2015, m2m extracted a representative sample of their longitudinal client records to assess the relationship between exposure to facility-based MM visits, and key client health and behavioural outcomes along the PMTCT cascade.
**Methods:** A stratified random sampling approach was used to identify a representative sample of 87 out of 350 m2m supported facilities in Kenya, Lesotho, Uganda, South Africa, Swaziland and Malawi. A census of longitudinal clients records was taken for clients (n=12 976) first enrolled in mothers2mothers care between June and November 2012, and concluding care in December 2014. Exposure status of clients to the m2m model was defined retrospectively by dividing the sample into a low exposure group comprised of clients who had one MM visit after an outcome under investigation had occurred and a high exposure group who had two or more MM visits before an outcome under investigation had occurred. Multivariate regression was then used to explore group differences after adjusting for key confounders.
**Results:** Women with two or more MM visits were more likely to have an infant who was HIV-negative at the final test (AOR =6.4, p< 0.001). MM visit exposure status was also positively associated with key behavioural and PMTCT uptake indicators (see Table).

| | | Adjusted odds ratios | | Unadjusted Frequencies | |
|---|---|---|---|---|---|
| Indicator | | AOR | p-value | 2+ m2m visits | 1 m2m visit |
| Maternal Behavioural Outcomes | Using Family Planning | 1.26 | 0.012 | 74% | 65% |
| | Exclusive breast feeding first 6 months | 1.67 | <0.001 | 84% | 75% |
| Uptake of Maternal PMTCT Services | Antenatal Prophylaxis | 3.86 | <0.001 | 96% | 77% |
| | Postnatal Prophylaxis | 2.27 | <0.001 | 86% | 74% |
| Uptake of Infant PMTCT Services | Infant prophylaxis | 1.60 | 0.017 | 96% | 93% |
| | Infant CPT | 1.63 | 0.001 | 78% | 72% |
| | 6-8 week PCR test | 2.31 | <0.001 | 75% | 52% |
| Impact - Mother-to-Child Transmission Rate at 18 Months | Infant HIV status HIV-negative | 6.4 | <0.001 | 93% | 70% |

*[Association between MM visit exposure and key behavioural and PMTCT uptake indicators]*

**Conclusions:** Within a longitudinal cohort of clients receiving m2m support, exposure to more Mentor Mother visits appears to be positively associated with better client behavioural and PMTCT outcomes along the treatment cascade. The study builds a pervasive case for the efficacy of peer-to-peer support models delivered by a paid cadre of lay councillors at the facility level.

## TUAE0102

### Increasing retention of HIV-positive pregnant and postnatal women and HIV-exposed infants: measuring the effects of follow-up activities and improved patient management in rural Uganda

J. Joseph[1], K. Suggu[1], N. Hariharan[1], G. Esiru[2], E. Yavuz[1], J. Gross[1], B. Mirembe[3]
*[1]Clinton Health Access Initiative, Boston, United States, [2]Ministry of Health, AIDS Control Programme, Kampala, Uganda, [3]Clinton Health Access Initiative, Kampala, Uganda*
*Presenting author email: jjoseph@clintonhealthaccess.org*

**Background:** In March 2013, Uganda adopted Option B+, providing lifelong antiretroviral therapy (ART) for all HIV+ pregnant women; however, only 40% of mother-infant pairs were retained in care by the end of the breastfeeding period. Retention must improve in order to achieve Uganda's goal of eliminating mother-to-child-transmission. A pilot was conducted in 2014 to evaluate the effectiveness of a package of interventions consisting of phone and home-visit follow-ups, strengthening the use of appointment books to track attendance, and patient-held appointment calendars. The study's objective was to determine if retention increased for both HIV+ pregnant/postnatal women and HIV-exposed infants.
**Methods:** A pre-post study was designed, selecting 20 rural facilities from six districts. Data were collected retrospectively for six months prior to and six months during the pilot period. Retention was defined as a woman or infant remaining in care for a minimum of five months after enrolment into the cohort, determined by the ART visit schedule. Retention rates were assessed by facility using weighted paired t-tests on cluster-level summaries.
**Results:** 686 women and 358 infants were included in the pre-pilot implementation period; 604 women and 332 infants during the pilot. Retention in care for mothers increased from 72.8% to 80.3% (p=0.009). This was driven by women who initiated on ART during pregnancy, as their retention rates increased from 68.5% to 76.0% (p=0.031). Women under 20 had almost three times more of an increase in retention compared to women of older ages. Retention for HIV-exposed infants increased from 41.3% to 61.1% (p=0.001). 30% of appointments were missed during the pilot program requiring follow-up, of those missed appointments, 28% received followed-up. There was a 70% return rate for missed appointments relative to a 12% return rate for appointments that received no follow-up.
**Conclusions:** The results of the pilot showed a significant impact on retention that will result in fewer HIV+ infants and better health outcomes for HIV+ mothers. Despite a low missed visit follow up rate, when conducted, the impact was substantial. In January 2016 Uganda adopted this model to be the national standard of care for follow-up of mother-infant pairs in all PMTCT sites nationwide.

### Impact of a systems engineering intervention on PMTCT service delivery in Côte d'Ivoire, Kenya, Mozambique: the SAIA cluster randomized trial

K. Sherr[1,2], A. Silvis Rustagi[1], S. Gimbel[3], R. Nduati[4,5], F. Cuembelo[6], A. Kone[2], C. Farquhar[7], J. Wasserheit[7], S. Gloyd[7], C. de Schacht[2], SAIA Study Team
*[1]University of Washington, Global Health, Seattle, United States, [2]Health Alliance International, Seattle, United States, [3]University of Washington, School of Nursing, Seattle, United States, [4]Network of AIDS Researchers of Eastern and Southern Africa, Nairobi, Kenya, [5]University of Nairobi, Paediatrics, Nairobi, Kenya, [6]Eduardo Mondlane University, Maputo, Mozambique, [7]University of Washington, Seattle, United States*
*Presenting author email: carolineds11@gmail.com*

**Background:** Improving pMTCT effectiveness requires increasing the number of women-infant pairs passing through the multiple, sequential steps in the pMTCT cascade, and associated access to efficacious interventions. The Systems Analysis and Improvement Approach (SAIA) trial tested a package of systems engineering techniques to improve cascade flow. Prior systems engineering applications for pMTCT lacked comparison groups or randomization.
**Methods:** The five-step SAIA intervention addresses cascade inefficiencies through 1) cascade analysis using an automated pMTCT Cascade Analysis Tool (P-CAT) with optimization function to identify largest potential gains across the cascade; 2) process mapping to identify workflow modifications; and 3-5) rapid, iterative testing of workflow modifications. A nine-month cluster randomized trial was conducted in 18 intervention/18 control facilities in Kenya, Côte d'Ivoire, and Mozambique, stratified by country and clinic volume. Registry data quantified HIV testing during first antenatal care (ANC) visit, antiretrovirals (ARVs) for HIV-positive pregnant women, and screening HIV-exposed infants (HEI) by 6-8 weeks. Change between baseline (01/2013-01/2014) and post-intervention (01/2015-03/2015) periods were compared using *t*-tests via intent-to-treat analyses.
**Results:** Seventeen of 18 intervention facilities accepted the intervention. An average of one cycle was completed monthly falling into five categories: service

reorganization; expanding patient knowledge; improving team communication; improving data quality; and introducing new norms or technologies. Examples of service reorganization include increasing blood draw frequency (increasing CD4 testing from 25% to 56%), and reorganizing ANC flow (reducing wait times from 7.5 to 3.5 hours). ARV coverage increased three-fold, and HEI screening increased 17-fold in intervention vs. control facilities, though differences were not significant overall. In pre-specified sub-group analyses, ARV coverage increased significantly in Kenya (+20.9% [95% CI: -3.1-44.9] in intervention vs. -21.2% [-52.7-10.4] in controls; p=0.02). HEI screening increased significantly in Mozambique (+23.1% [10.3-35.8] in intervention vs. +3.7% [-13.1-20.6] in controls; p=0.04). HIV testing did not differ significantly between arms.

**Conclusions:** This first randomized trial of systems engineering to improve PMTCT saw substantially larger improvements in ARV coverage and HEI screening in intervention facilities compared to controls, which were significant in pre-specified sub-groups. The SAIA intervention was feasible and well-accepted by facility staff. Systems engineering could strengthen PMTCT services and protect infants from HIV.

## TUAE0104

### RETURNING HIV-EXPOSED INFANTS TO CARE: RESULTS FROM A PILOT INTEGRATING INFANT DEFAULTER TRACING INTO THE NATIONAL OPTION B+ PROGRAMME IN LILONGWE, MALAWI

E. Kamanga[1], G. Banda[1], I. Mofolo[1], G. Mwale[1], M. Mwale[2], J. Chikonda[1], J. Sherman[3], J. Chinkonde[3], M. Herce[1,4]
*[1]University of North Carolina Project-Malawi, Lilongwe, Malawi, [2]Ministry of Health, Lilongwe District Health Office, Lilongwe, Malawi, [3]UNICEF, HIV and AIDS Section, Lilongwe, Malawi, [4]University of North Carolina at Chapel Hill, Department of Medicine, Division of Infectious Diseases, Chapel Hill, United States*
*Presenting author email: ekamanga@unclilongwe.org*

**Background:** Despite high uptake of prevention of mother-to-child transmission (PMTCT) services early in the care continuum in Malawi's Option B+ Programme, including HIV counseling and testing (90%) and antiretroviral therapy (ART, 79%), challenges remain with the post-natal care continuum, including high loss to follow-up (40% by 24 months of age) for HIV-exposed infants (HEIs). Poor HEI care retention undermines early diagnosis and treatment of HIV-infected infants, and threatens progress in reducing vertical HIV transmission in Malawi and elsewhere in sub-Saharan Africa. In response to this challenge, in October 2013 we launched an HEI "defaulter" tracing program at 20 health facilities in Lilongwe selected for high HEI census as part of the UNICEF Optimizing HIV Treatment Access (OHTA) Initiative to increase timely uptake, adherence, and retention along the PMTCT care continuum.

**Methods:** We trained and mentored 737 community-based Health Surveillance Assistants (HSAs) from Ministry of Health (MOH) to perform tracing via phone contact and/or home visit. HSAs were mentored on accurate reporting using data collection tools from the MOH National HEI Follow-Up Programme, as well as OHTA-specific defaulter-tracing and HEI appointment registers. To support physical tracing, we provided 30 bicycles to health facilities and all HSAs with a modest monetary incentive (~$2 USD) for every HEI successfully reached.

**Results:** From October 2013—September 2015, we traced 2,707 HEIs who had fallen out of care (i.e. missing a scheduled follow-up appointment by ≥14 days). Of these, 2,078 HEIs (76.8%) were successfully reached by phone or home visit. Following tracing, 1,969 of 2,078 reached HEIs (94.8%) returned to clinic and were retained in care as assessed at 2, 12, or 24 months of age (depending on HEI age at the time of tracing). Of these, 50 HIV-infected infants were identified (2.5%, 50/1,969) and all initiated ART (100%, 50/50).

**Conclusions:** Integrating HEI defaulter tracing into the public health system facilitated improved HIV care retention for HEIs, and successful HIV diagnosis and ART initiation for HIV-infected infants. Such an approach, implemented by community agents receiving mentorship, incentives, and field supervision, may be a strategy to strengthen HEI care retention and the post-natal PMTCT care continuum in Malawi.

## TUAE0105

### A MULTIPRONGED APPROACH TO THE ELIMINATION OF MTCT IN SOUTH AFRICA

K. Ng'oma[1], T. Mtileni[2], I. Odongo[3], P. Robinson[4], M. Mogashoa[5], S. Bhardwaj[1], P. Holele[2], Y. Pillay[2]
*[1]UNICEF, Pretoria, South Africa, [2]National Department of Health, Pretoria, South Africa, [3]mothers2mothers, Pretoria, South Africa, [4]Right to Care, Johannesburg, South Africa, [5]CDC, Pretoria, South Africa*

**Background:** South Africa has the highest number of people living with HIV in the world, estimated at 6.4 million in 2012, with HIV prevalence of 29.5% in antenatal women, and mother-to-child transmission (MTCT) rate estimated at 3.5% at 6 weeks in 2010. In response to the Global Plan *towards the elimination MTCT*, the National Department of Health (NDOH) developed and implemented the national elimination MTCT Action Framework entitled "No child born with HIV by 2015 and improving the health and wellbeing of mothers, partners and babies in South Africa". The framework enabled evidence-based, accelerated, programme scale-up and delivery of quality services, with innovative data-driven action plans in all provinces and districts.

**Description:** Five key strategic pillars were identified for scaling up quality integrated prevention of MTCT services. Political leadership and commitment at the highest level resulted in accelerated national HIV response, including EMTCT. Responsive changes in policy, for example, the move from single dose Niverapine to more efficacious triple antiretroviral (ART) regimens for PMTCT, coupled with quality improvement initiatives and task shifting, resulted in rapid scale-up of quality EMTCT services. PMTCT was integrated into the maternal, child and women's health programme to maximise service delivery platforms. The routine use of 'robot' dashboards and data for action reports ensured continuous monitoring of programme performance, and action planning. Significant progress was made towards targets of the plan. The number of children newly infected with HIV in South Africa declined by over 70% (2009 -2014). Over 90% of HIV positive women were receiving treatment for PMTCT (2015), a significant increase from the 63% in 2009. The coverage of early infant diagnosis of HIV increased from 45% in 2009 to 87% in 2014, MTCT rate declined to 2.6% in 2012/2013. Infant HIV positivity rates at around 6 weeks declined from 5.8% in 2009 to 1.5% in 2015.

**Lessons learned:** High level political leadership, strong partnerships and robust monitoring and evaluation systems helped to accelerate response to elimination of MTCT.

**Conclusions/Next steps:** An evidence-based multipronged approach was critical for the success seen in the journey towards the elimination of MTCT in South Africa.

## TUAE0106

### HIGHEST RISK OF MOTHER TO CHILD TRANSMISSION OF HIV OR DEATH IN THE FIRST 6 MONTHS POSTPARTUM: RESULTS FROM 18 MONTH FOLLOW-UP OF AN HIV-EXPOSED NATIONAL COHORT, SOUTH AFRICA

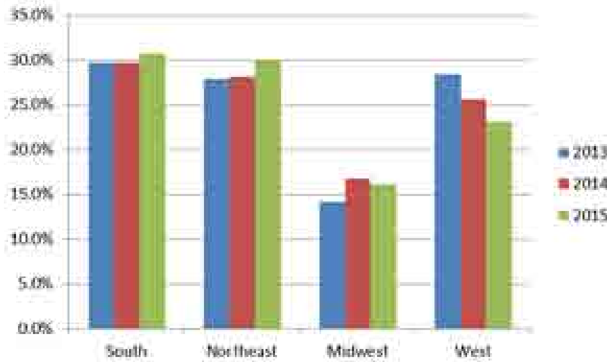
A. Goga[1,2], D. Jackson[3,4], C. Lombard[5,6], V. Ramokolo[5], N. Ngandu[5], G. Sherman[7,8], A. Puren[7,9], T. Doherty[4,5,7], S. Bhardwaj[10], N. Noveve[5], T. Ramraj[11], V. Magasana[11], Y. Singh[11], Y. Pillay[12], South African PMTCT Evaluation Study Group
*[1]South African Medical Research Council, Pretoria, South Africa, [2]University of Pretoria, Department of Paediatrics, Pretoria, South Africa, [3]UNICEF, New York, South Africa, [4]University of the Western Cape, Cape Town, South Africa, [5]South African Medical Research Council, Cape Town, South Africa, [6]University of Cape Town, Cape Town, South Africa, [7]University of Witwatersrand, Johannesburg, South Africa, [8]National Insitiute of Communicable Diseases, Johannesburg, South Africa, [9]National Institute of Communicable Diseases, Johannesburg, South Africa, [10]UNICEF, Pretoria, South Africa, [11]South African Medical Research Council, Durban, South Africa, [12]South African National Department of Health, Pretoria, South Africa*
*Presenting author email: ameena.goga@mrc.ac.za*

**Background:** Few resource-limited, high HIV prevalence settings produce data on national 18-24 month infant 'mother-to-child transmission of HIV (MTCT)-or-death' - the gold standard measurement of programme impact. We studied South African national MTCT and 'MTCT-or-death' when health policy provided infant nevirapine during breastfeeding (Option A) and changed to triple antiretroviral therapy for all HIV infected women during pregnancy and lactation (Option B).

**Methods:** A nationally representative cross-sectional survey was conducted to estimate early (4-8 weeks postpartum) MTCT. Facilities (n=580) were randomly selected following multistage probability proportional to size sampling methodology. Consenting caregivers of systematically or consecutively sampled infants (4-8 weeks old) receiving their six week immunisation, were interviewed. Infant dried blood spot specimens (iDBS) were drawn and tested for HIV exposure and, if positive, for infection (total nucleic acid polymerase chain reaction - TNA PCR). Then, all HIV exposed infants (antibody, or maternal self-reported positive) were invited for facility-based follow-up at 3, 6, 9, 12, 15 and 18 months. At each follow-up visit caregivers were interviewed and infants were tested for HIV infection). Analysis was weighted for sample ascertainment, population live births, consent to follow-up (if eligible) and loss to follow-up.

**Results:** Analysis of 9120 iDBS at 4-8 weeks revealed 33.1% infant HIV exposure (95% Confidence Interval, 31.8-34.3%) and 2.6% (2.0-3.2) MTCT. 1880 (71%) HIV-exposed infants were followed up at 18 months. Cumulative MTCT and 'MTCT-or-death' by 3, 6, 9, 12, 15, months was 2.7% (2.6-12.6) and 2.8% (2.6-19); 3.5% (3.1-4.4) and 4.2% (3.5-5.4); 3.7% (3.2-4.6) and 5.1% (4.4-6.2); 3.9% (3.4-4.7) and 5.7% (5.0-6.8); 4.1% (3.5-4.8) and 6.0% (5.2-7.0), and at 18 months, 4.3% (3.7-5.0) and 6.2% (5.5-7.3) respectively. 81% of MTCT and 67% of 'MTCT-or-death' occurred by 6 months postpartum. Maternal receipt of CD4-cell-count result and avoiding breastfeeding protected against MTCT (Adjusted hazard ratio HRa, 0.3 [0.2-0.6], and 0.3, [ 0.07-0.9],respectively). Mixed feeding and infant nevirapine did not significantly

**Methods:** We used nationally representative (82% of retail pharmacies) de-identified data (Symphony Health Analytics) on individuals who received a TVD prescription from Jan 2013 to Dec 2015. The data warehouse contains medical claims, diagnosis codes, and patient and provider demographics. A validated algorithm was used to quantify TVD for PrEP use by excluding TVD for HIV treatment, HIV post-exposure prophylaxis and chronic Hepatitis B treatment. Logistic regression analyses were used to compare demographic data from TVD use for HIV treatment or PrEP.
**Results:** Between January 2013 and December 2015, 49,469 unique individuals started TVD for PrEP: 3,746 in 2013; 14,756 in 2014; 30,967 in 2015. 87.5% were male. Mean age was 37.4 years, with 11.5% under age 25. Fig 1 shows regional distribution of TVD PrEP starts over time. There were 19,274 prescribers across 50 states. Four states (CA, NY, TX, FL) with the highest HIV incidence account for 43.0% of PrEP starts. Compared to HIV positive patients, uninfected individuals receiving TVD for PrEP were 3.1 times less likely to be female (95% CI 3.0 - 3.2), but 1.98 times more likely to be under age 25 (95% CI 1.93 - 2.05).



*[Fig 1: Distribution by region over time]*

**Conclusions:** The number of individuals starting on TVD for PrEP has increased nationally since the 2012 approval in the US, and is primarily male. States with the highest number of new HIV cases also had the highest number of TVD PrEP starts. Despite positive trends in TVD for PrEP use, utilization must increase to ensure lifetime risk seroconversion decreases in areas of high prevalence HIV in the US.

## TUPDA01 HIV TRANSMISSION AND PATHOGENESIS

### TUPDA0101

### SELECTION OF HIV-1 VARIANTS WITH HIGHER TRANSMISSION POTENTIAL BY 1% TENOFOVIR GEL MICROBICIDE

N. Ngandu[1,2], J. Carlson[3], D. Chopera[1,4], N. Ndabambi[1], S. Goodier[1], N. Garrett[4], N. Samsunder[4], Q. Abdool Karim[4], S. Abdool Karim[4], C. Williamson[1,4]

*[1]University of Cape Town, Pathology, Cape Town, South Africa, [2]South African Medical Research Council, Health Systems Research Unit, Cape Town, South Africa, [3]Microsoft Research, Los Angeles, United States, [4]University of KwaZulu Natal, Centre for the AIDS Program of Research in South Africa, Durban, South Africa*

*Presenting author email: denis.chopera@gmail.com*

**Background:** Women in the CAPRISA 004 trial assigned to use 1% tenofovir microbicide gel had higher HIV-1 viral loads and slower antibody avidity maturation compared to placebo participants. This study sought to determine whether tenofovir gel selected for viruses with altered characteristics which, in turn, influenced disease progression.

**Methods:** We analysed bulk *gag* sequences from the earliest time-point post-infection for 71 (n=28 TFV and n=43 placebo) participants who became infected during the CAPRISA 004 microbicide trial conducted in Durban, South Africa. The median (IQR) days post infection at which the sequence data were obtained were 84 (84-91) for women assigned to tenofovir gel and 84 (77-84) for women assigned to placebo. Genetic distances between sequences were estimated in MEGA version 5.1 (Tamura, Peterson et al., 2011). The transmission index of a sequence was calculated as the mean of the expected log-odds of transmission for each site in the sequence, as estimated by a logistic regression model that included a second-order polynomial of cohort frequency, the number of co-varying sites, and offsets and cohort-frequency interactions for each protein domain. Transmission indices were computed out-of-sample using leave-one-out cross-validation.

**Results:** Sequences from the two groups (tenofovir and placebo) of the trial were interspersed on the phylogenetic tree, showing no lineage effects on the viruses infecting the two groups. Viruses within the tenofovir group were less diverse from each other compared to those from the placebo group (p< 0.0001), suggesting constrained diversity of viruses infecting the tenofovir group. Furthermore, viruses from the tenofovir group were closer to the consensus sequence of regional strains (p=0.003), and had higher transmission index (p=0.01), than those from the placebo group. There was a modest correlation between the transmission index and the baseline viral load (Spearman r=0.2, p=0.04) but not with viral load at set-point (12 months post-infection).

**Conclusions:** The 1% tenofovir gel may have increased the transmission barrier to select for more consensus-like viral variants with a higher transmission index.

### TUPDA0102

### CHARACTERIZATION OF HIV-1 GENOMES FROM 74 ACUTELY INFECTED SUBJECTS IN THE ACUTE INFECTION COHORT RV217

M. Rolland[1], S. Tovanabutra[1], G. Kijak[1], E. Sanders-Buell[1], M. Bose[1], C. Owen[1], L. Maganga[2], S. Nitayaphan[3], K. Rono[4], A. Sekiziyivu[5], L.A. Eller[1], J. Kim[6], N. Michael[6], M. Robb[1]

*[1]Military HIV Research Program, Silver Spring, United States, [2]MMRP, Mbeya, Tanzania, United Republic of, [3]AFRIMS, Bangkok, Thailand, [4]WRP-Kericho, Kericho, Kenya, [5]MUWRP, Kampala, Uganda, [6]MHRP, Silver Spring, United States*

*Presenting author email: mrolland@hivresearch.org*

**Background:** Since the early events of HIV infection are critical for disease progression and provide a path to develop anti-HIV strategies, we analyzed viral evolution during the first six months of HIV infection in 74 treatment-naive individuals enrolled in the RV217 acute infection cohort in East Africa and Thailand.

**Methods:** More than 2,000 HIV-1 negative individuals were enrolled and bi-weekly testing for HIV-1 RNA allowed to identify subjects during the earliest days of infection in Kenya (n = 9), Tanzania (n = 18), Uganda (n = 18) and Thailand (n = 29). HIV-1 genomes were sequenced following PCR amplification by endpoint-dilution from plasma samples.

**Results:** We sequenced 802 HIV-1 genomes from 74 subjects at a median of four days after HIV-1 diagnosis, a diagnosis that occurred a median of six days after the last negative visit. For a subset of 42 individuals, we sequenced 857 additional genomes obtained at a median of 32 and 171 days post HIV diagnosis. Sequences from the first time point were obtained before peak viremia, which occurred 12 days after diagnosis with viral loads reaching 6.55 $\log_{10}$ copies/ml (range: 3.96-8.46 $\log_{10}$ copies/ml). The median viral load setpoint (SPVL) was 4.31 $\log_{10}$ copies/ml (range: 2.43-5.96 $\log_{10}$ copies/ml). In East Africa, most individuals (n = 25) were infected with circulating recombinant forms (CRF) comprising subtype A1, C and D with 13 individuals infected with subtype A1 and seven with subtype C; in Thailand, 23 of 29 subjects were infected with CRF01_AE.

We identified multiple HIV-1 variants among sequences from 18 of 48 subjects, with some variants found at very low level initially and some variants being identified only temporarily. SPVL for subjects replicating multiple founders was significantly higher than for subjects with single founders (4.82 vs. 4.08 $\log_{10}$ copies/ml, p = 0.021).

**Conclusions:** Analysis of HIV-1 sequences earlier in infection and more frequently than before revealed a greater complexity in HIV-1 evolutionary processes and identified viral determinants associated with higher viral loads. Identifying HIV-1 features that determine SPVL will allow to better predict the transmission risk associated with specific HIV-1 variants.

### TUPDA0103

### HIV-ASSOCIATED ALTERATION IN GUT MICROBIOTA ARE ASSOCIATED WITH INCREASED INFLAMMATION AND INFECTION OF ENTERIC CD4+ T CELLS

B. Palmer, C. Neff, S. Li, J. Schneider, T. Campbell, C. Lozupone

*University of Colorado, Denver, Medicine, Aurora, United States*

*Presenting author email: brent.palmer@ucdenver.edu*

**Background:** HIV infection is associated with dramatic alterations of the enteric microbiome that often persist despite long-term otherwise successful Antiretroviral Therapy (ART). Alterations in gut microbiota have been correlated with HIV disease progression, inflammatory markers in the gut and with inflammatory and bacterial translocation markers in blood. A better understanding of the immune-modulatory properties in gut microbes that correlate with disease will allow for the exploration of microbial drivers of immune activation, HIV disease pathogenesis and co-morbidity.

**Methods:** We are collecting gut microbiome data from a large cohort of individuals living in Colorado and identifying bacteria whose prevalence correlates with disease status, ART, and with inflammatory and metabolic disease markers. To explore the immune-modulatory properties of these bacteria, we culture peripheral blood mononuclear cells (PBMC) and lamina propria mononuclear cells (LPMC) isolated from resected gut tissue with bacteria isolated from patient stool and cultured bacteria that are increased or decreased with HIV infection. We then measure the impact of the stimulation on pro and anti-inflammatory cytokines, T cell activation, T regulatory cells, HIV co-receptors and levels of HIV infection.

**Results:** Many bacterial species significantly change with HIV and correlate with inflammatory and translocation markers in blood in our study population. Although stimulations of PBMC/LPMC with most bacteria induce both pro and anti-inflammatory cytokines, cultured bacteria that increase with HIV and fecal bacteria from HIV-infected individuals induce lower levels of T regulatory cells and anti-inflammatory IL-10. Furthermore, incubation of LPMCs with numerically dominant bacteria of the HIV-associated (*Prevotella copri*) but not health-associated (*Bacteroides uniformis*) gut microbiome resulted in increased infectivity of immune cells by HIV.

**Conclusions:** These data suggest that a loss of anti-inflammatory (beneficial) bacteria with HIV infection has the potential to drive chronic inflammation observed in HIV-infected individuals. Furthermore, our infectivity assays indicate a potential role of the HIV-associated gut microbiome in disease transmission and progression. We are currently further exploring microbiome associations with HIV disease, inflammation and metabolic disease in populations in both the US and Zimbabwe.

### THE ASSOCIATION OF INJECTABLE PROGESTIN-ONLY CONTRACEPTIVES AND ENDOGENOUS PROGESTINS WITH HIV TARGET CELL FREQUENCY IN THE CERVIX AND HIV ACQUISITION RISK

E.H. Byrne[1], M.N. Anahtar[1], K.E. Cohen[1], A. Moodeley[2], N. Padavattan[3], N. Ismail[3], B.A. Bowman[1], G.S. Olson[1], A. Mabhula[4], A. Leslie[4], T. Ndung'u[1,3,4], B.D. Walker[1,5,6], M.S. Ghebremichael[1], K.L. Dong[2], D.S. Kwon[1,5]

*[1]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [2]Females Rising through Education, Support and Health, Durban, South Africa, [3]HIV Pathogenesis Programme, Durban, South Africa, [4]KwaZulu Natal Research Institute for Tuberculosis and HIV, Durban, South Africa, [5]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States, [6]Howard Hughes Medical Institute, Chevy Chase, United States*

*Presenting author email: dkwon@mgh.harvard.edu*

**Background:** Multiple observational studies have suggested that injectable progestin-only contraceptives (IPCs) are associated with HIV acquisition risk. However, the biological mechanism of this potential link was unclear. We aimed to understand immunological changes associated with exogenous and endogenous progestins that could mechanistically help explain a link to acquisition risk.

**Methods:** HIV-negative South African women ages 18-23 were enrolled in a prospective cohort study, the Females Rising through Education, Support and Health (FRESH) study. These women were at high risk of acquiring HIV, were living in Umlazi and were not pregnant. During the study, they were tested for HIV-1 two times per week; behavioral data along with blood and cervical samples were collected every three months.

**Results:** We characterized 423 HIV-uninfected women from the FRESH cohort. Of these, 152 women used IPCs, 222 used no long-term contraceptive and 43 used other forms of contraception. IPC users had a higher risk of acquiring HIV (12.06 per 100 person-years, 95% CI 6.41-20.63) compared to women using no long-term contraceptive (3.71 per 100 person-years, 1.36-8.07; adjusted hazard ratio 2.93, 95% CI 1.09-7.868, p=0.0326). In the cervix, CCR5+ CD4 T cells (HIV target cells) were 3.92 times more prevalent in IPC users than in women using no long-term contraceptive (p=0.0241). Of women using no long-term contraceptive, those in the luteal phase of the menstrual cycle had 3.25 times the frequency of cervical target cells compared with those in the follicular phase (p=0.0488).

**Conclusions:** High progestin levels, either due to the use of IPCs or the luteal phase of the menstrual cycle, are associated with an increased frequency of HIV target cells in the cervix compared to women with low progestin levels, in the follicular phase of the menstrual cycle. Because the female genital tract is the site of HIV entry in most women who become infected, the higher density of HIV target cells in a high-progestin state provides a potential biological mechanism for the epidemiological observation of increased HIV acquisition risk in IPC users.

## TUPDA0105

### THE MECHANISMS AND ROLE OF HPV IN ENHANCING HIV TRANSMISSION IN WOMEN IN SOUTH AFRICA

L. Liebenberg[1,2], L.R. McKinnon[1,2,3], K. Leask[1], A. Rositch[4], N. Garrett[1], N. Samsunder[1], A. Kharsany[1], A. Grobler[1], A. Singh[1], J.-A. Passmore[1,5,6], S.S. Abdool Karim[1,7], Q. Abdool Karim[1,7]

*[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]University of KwaZulu Natal, Department of Medical Microbiology, Durban, South Africa, [3]University of Manitoba, Department of Medical Microbiology, Winnipeg, Canada, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [5]University of Cape Town, Cape Town, South Africa, [6]National Health Laboratory Service, Johannesburg, South Africa, [7]Columbia University, Department of Epidemiology, New York, United States*

**Background:** Young women bear a disproportionately high burden of sexually-acquired HIV infection. Human papillomavirus (HPV), a common sexually transmitted infection is a known contributor to this burden through its established association with higher rates of HIV acquisition. However, the mechanism of this relationship remains unclear. Here we explored whether the immunological impact of HPV promotes a mucosal immune environment that favours the establishment of HIV infection in young women in KwaZulu-Natal, South Africa.

**Methods:** This cohort study was nested within the CAPRISA 004 1% tenofovir gel study. Stored genital specimens from HIV uninfected participants (N=779) were utilized to determine the presence of 37 HPV genotypes using commercially available Linear Array kits. Concentrations of 48 cytokines were quantified by multiplexed ELISA assays, and the presence of $CD4^+$ targets for HIV infection was investigated by flow cytometry. HIV infection was monitored monthly using two commercially available rapid tests, and confirmed by western blot and PCR.

**Results:** Baseline HPV prevalence was 73.8% (95% CI: 70.7, 76.9); with 70.3% of these infected participants presenting with an oncogenic strain. Participants with prevalent HPV infection were 2.8 times more likely to acquire HIV infection compared to those without HPV infection (HR 2.8, 95% CI: 1.3, 5.9, p=0.006). HIV risk was independent of the oncogenicity of HPV strains at baseline [(HPV oncogenic strains HR 2.9 (95% CI: 1.3, 6.1) vs non-oncogenic strains HR 2.8 (95% CI: 1.3, 6.1)], and was also increased in the presence of multiple concurrent infections (HR 4.0; 95% CI: 1.8, 8.8). Compared to HPV uninfected women, acquisition, clearance, or persistence of HPV were each significantly associated with >6 fold increased rates of HIV acquisition, and elevated concentrations of several cytokines associated with HIV infection (including IL-8, MIP-1a, RANTES, IL-1a, IL-6). Further, in line with cytokine involvement in chemotaxis, the influx of CD4+ T cell targets for HIV infection was associated with HPV infection (p=0.012).

**Conclusions:** These data provide a plausible causal immunological link between two viral infections of critical public health importance, and suggest that increased HPV vaccination rates in young women could have important additional HIV prevention benefits.

## TUPDA0106

### THE ENDOTOXIN-LIPOPROTEIN HYPOTHESIS, OBESITY AND HIV

S. Martinez[1], A. Campa[1], F. Huffman[1], J. Makhema[2], S. Moyo[2], O.D. Williams[1], R. Marlink[3], M. Baum[1]

*[1]Florida International University, Miami, United States, [2]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [3]Harvard School of Public Health, Boston, United States*

*Presenting author email: saless@fiu.edu*

**Background:** An obesity paradox has been documented in many conditions including HIV infection, where those who are obese may have a survival advantage or improved disease outcomes. Lipopolysacchride (LPS), an endotoxin, is a constituent of Gram-negative bacterial cell walls and known to produce proinflammatory responses. Sequestration of LPS by higher circulating lipoproteins in obesity has been suggested as mechanism for the obesity paradox known as the endotoxin-lipoprotein hypothesis and warrants further investigation in HIV.

**Methods:** A retrospective cross-sectional analysis of data and specimens from a nutritional study was conducted in 60 HIV+ ART-naïve adults who were in the early stages of HIV disease in Botswana, Africa. Anthropometrics and bioimpedance were obtained. Blood was drawn for LPS, total cholesterol as a measure of circulating lipoproteins, CD4 count, and HIV viral load. Regression analyses were adjusted for age, gender and smoking.

**Results:** Among 60 ARV-naïve HIV+ asymptomatic adults, the median age was 33 years (IQR: 29-39) and 76.4% were women. The overweight/obese group had higher total cholesterol levels (4.08±0.85 vs. 3.50±0.65 mmol/L, P=0.007) than the normal weight group. Plasma LPS levels at or above the median (0.058 EU/mL) were associated with lower BMI (OR=.79; 95% CI: 0.630, 0.990; P=0.041), lower fat mass% (OR=0.852, 95% CI: 0.757, 0.958, P=0.007), and higher HIV viral load (OR=2.608, (95% CI: 1.111, 6.124; P=). Higher LPS levels were also associated with a lower odds of overweight/obesity, BMI ≥ 25 kg/m$^2$ (OR=0.035, 95% CI: 0.004, 0.283; P=0.002). LPS levels at or above the median were also associated with lower total cholesterol levels (OR=0.360, 95% CI: 0.150-0.862; P=0.022), controlling for age, gender, smoking, and HIV viral load.

**Conclusions:** A possible explanation for the lower levels of LPS observed in those with higher BMI might be similar to the endotoxin lipoprotein hypothesis first described by Rauchhaus et al. (2000) to explain the endotoxin lipoprotein paradox in congestive heart failure. Higher circulating lipoproteins may reduce inflammation by binding to lipopolysacchrides and decreasing the release of proinflammatory cytokines. In HIV infection, viral load contributes to increased LPS.

## TUPDB01 HIV DRUG RESISTANCE: IS IT TIME TO WORRY?

### TUPDB0101

### ASSESSMENT OF THE WORLD HEALTH ORGANIZATION EARLY WARNING INDICATORS OF HIV DRUG RESISTANCE IN NAMIBIA FOR PUBLIC HEALTH ACTION, 2015

N. Mutenda[1], T. Nakanyala[1], N. Hamunime[1], T. Mekonen[1], F. Tjituka[1], S. Natanael[1], G. Mazibuko[2], S. Mwinga[2], D. Mabirizi[3], E. Sagwa[2], H. Walkowiak[4], A. Kiesling[5], S. Aptekar[5], M. Jordan[6], S. Hong[5,6]
*[1]Ministry of Health and Social Services, Directorate of Special Programmes, Windhoek, Namibia, [2]Management Sciences for Health, Systems for Improved Access to Pharmaceuticals and Services Program, Windhoek, Namibia, [3]Management Sciences for Health, Systems for Improved Access to Pharmaceuticals and Services Program, Arlington, United States, [4]Management Sciences for Health, Systems for Improved Access to Pharmaceuticals and Services Program, New York, United States, [5]Tufts University School of Medicine, Department of Public Health and Community Medicine, Boston, United States, [6]Tufts Medical Center, Division of Geographic Medicine and Infectious Diseases, Boston, United States*
*Presenting author email: shong@tuftsmedicalcenter.org*

**Background:** Early warning indicators (EWIs) of HIV drug resistance (HIVDR) are a key element of the World Health Organization (WHO) public health strategy to minimize and monitor emergence of HIVDR at facilities providing antiretroviral treatment (ART) in countries that are rapidly scaling up treatment. Namibia has instituted a routine EWI monitoring system and developed HIVDR survey strategies.
**Methods:** In 2015, we abstracted the following WHO EWIs from adult and paediatric patients from all ART sites in the state health sector. These included, 50 main ART sites and 163 Integrated Management of Adolescent and Adult Illness (IMAI) sites and outreach points): *EWI 1: On-time Pill Pick-up, EWI 2: Retention in Care at 12 months, EWI 3: Pharmacy Stock-outs, EWI 4: Dispensing Practices,* and *EWI 5: Viral Suppression at 12 months*.
**Results:** All 213 ART sites in Namibia were included. For *EWI 1*, 43% of sites achieved either excellent or fair performance (>90% or 80-90% of patients on-time collection) for adults and 40% for children. For *EWI 2,* 53% of sites achieved either excellent or fair performance (>85% or 75-85% retention) for adults and 37% for children. For *EWI 3,* 5% of sites achieved excellent performance (100% of months with no stock-outs) for adult patients and 14% for children. For *EWI 4,* 97% of sites achieved excellent performance (0% mono- or dual-therapy) in adults and 91% for children. For *EWI 5*, low rates of viral load (VL) completion among patients eligible for routine VL testing significantly affected monitoring of viral suppression.
**Conclusions:** Namibia has successfully institutionalized EWI monitoring into routine ART program functioning. Strengthening patient adherence to treatment, retention in care, and ensuring the continuous availability of antiretroviral medicines are all high priorities to minimize emergence of HIVDR and achieve the 90-90-90 (HIV epidemic control) goals. Additionally, improving routine VL monitoring and data capturing is a priority to enable monitoring of viral suppression rates. As a result of these data, program leaders and healthcare providers in regions throughout the country are implementing service quality improvement projects and operational research to improve patient care and minimize the emergence of HIVDR.

### TUPDB0102

### HIGH PREVALENCE OF ANTIRETROVIRAL DRUG RESISTANCE AMONG HIV-INFECTED PREGNANT WOMEN IN BUENOS AIRES, ARGENTINA

I. Zapiola[1], D.M. Cecchini[2], S. Fernandez Giuliano[1], M. Martinez[2], C.G. Rodriguez[2], M.B. Bouzas[1]
*[1]Hospital Muñiz, Virology Unit, Buenos Aires, Argentina, [2]Hospital Cosme Argerich, Working Group in Prevention of Mother-to-Child Transmission, Buenos Aires, Argentina*
*Presenting author email: diegocec@gmail.com*

**Background:** The presence of primary mutations in the viral genome is a major cause of drug resistance, which can lead to treatment failure. Thus, monitoring the presence of drug resistance-associated mutations (RAMs) in HIV-infected pregnant women (HPW) is crucial for optimizing antiretroviral therapy (ART) selection. Until recently, genotypic resistance tests were not routinely available for HPW in Argentina and information about the prevalence of RAMs in this population is limited.
**Objective:** To determine trends in the prevalence of RAMs in HPW assisted in a public hospital in Buenos Aires, Argentina.
**Methods:** HPW were recruited as part of a prospective sentinel epidemiological survey (period 2008-2014). Baseline plasma samples were sequenced using TRUGENETM HIV-1 Genotyping Kit. RAMs were identified in ART-naive and ART-experienced patients, according to the WHO guidelines and the IAS-USA mutation list, respectively. RAMs prevalence was compared for two periods: 2008-2011 vs. 2012-2014.
**Results:** Overall, 136 HPW were included: 77 (56.6%) naïve and 59 (43.4%) ART-experienced (24 with ongoing ART and 35 with a history of exposure to ART). A total of 37 (27.2%) women had at least one RAM: 25/94 (26.5%) in 2008-2011 and 12/42 (28.5%) in 2012-2014 (p>0.05). Among the naïve, 15 (19.5%) had at least one RAM: 10/49 (20.4%) in period 2008-2011 and 5/28 (17.8%) in 2012-2014 (p>0.05). Transmitted resistance was observed mainly for non-nucleoside reverse transcriptase inhibitors (NNRTIs): 14.3% in 2008-2011 and 17.8% in 2012-2014, being K103N the most common mutation. Among the ART-experienced HPW, 37.3% had RAMs: 33.3% in 2008-2011 and 50% in 2012-2014 (p>0.05). In the experienced HPW with ongoing ART subgroup, 50% had nucleoside reverse transcriptase inhibitors-RAMs and 45.8% had NNRTI-RAMs. In the experienced group with a history of (but not ongoing) ART-exposure, 17.1% had NNRTI-RAMs.
**Conclusions:** This sentinel study demonstrates an overall high prevalence of RAMs in HPW in Buenos Aires city, which remained stable over the two periods analyzed. Considering the >15% prevalence found in naïve HPW is above the threshold suggested by WHO for routine resistance surveillance in a certain population, access to genotypic tests should be warranted.

### TUPDB0103

### HIV-1 DRUG RESISTANCE AND GENETIC DIVERSITY IN ART-NAÏVE PATIENTS INFECTED IN 2013-2015 IN KAZAKHSTAN

N. Dzissyuk, A. Abishev, A. Zhanpeisova, G. Nagashbekova, G. Tazhibayeva
*Republican Center for Prevention and Control of AIDS, Almaty, Kazakhstan*
*Presenting author email: science@rcaids.kz*

**Background:** Treatment of HIV-positive patients in Kazakhstan was launched 10 years ago. Every year an increasing number of cases of HIV-1 drug resistance among patients with failing first-line antiretroviral therapy. The aim of the study was to analyze prevalence of HIV drug resistance in ART-naïve patients infected in 2013-2015 in Kazakhstan.
**Methods:** 376 plasma samples from newly HIV-infected patients from 8 regions of Kazakhstan were tested. Isolation of HIV RNA, RT-PCR, sequencing of *pro* (1-99) and *rev* (35-265) genes were performed using diagnostic kit "AmpliSens-HIV-Resist-Seq». For interpretation of HIV drug resistance the software "Deona" was used. HIV subtypes were determined using the program Comet HIV-1 (http://comet.retrovirology.lu). The level of transmitted HIV drug resistance was determined by the software CPR (http://cpr.stanford.edu/cpr.cgi).
**Results:** In the study group the patients were 56.6% males; median age: 35,7 years; median CD4: 478/mm$^3$; risk factors: heterosexuals (64.7%), MSM (3.0%), IDUs (31.4%), unknown (0.9%).
56.1% were infected with subtype of HIV-1 A1 (IDU-A variant); 38.6% - CRF02_AG; 2.9% - subtype B; 2.4% - other (CRF03_AB, CRF07_BC and URF). CRF02_AG is more prevalent in the southern regions of Kazakhstan (70.4% - 85.0%), while in the central and eastern regions of the country dominated HIV-1 subtype A1 (55.1% - 96.2%).
The presence of mutations of HIV-1 resistance to first-line antiviral drugs among ART-naïve patients have been identified in six regions of Kazakhstan (from 1.9% to 4.2%). In three patients (0.8%) were identified TAMs to NRTIs: M41L, L210W and K219E/R. In four patients (1.1%) were identified resistance mutations to NNRTI: K101E, K103N, Y181C.
**Conclusions:** The study showed that in Kazakhstan the level of primary HIV-1 drug resistance to NRTI/NNRTI is low. The highest level (4.2%) of primary HIV-1 drug resistance observed in large cities, where there is the greatest number of patients on ART.

*Presenting author email: birgit.schramm@epicentre.msf.org*

**Background:** With access to viral load (VL) monitoring, the number of patients receiving second-line antiretroviral treatment (ART) is increasing in resource-limited countries. We assessed virological response and second-line drug resistance in three large HIV-programmes to inform regimen-requirements, to evaluate patient outcomes and support forecasting of effective third-line drugs.

**Methods:** Between November 2014 and December 2015, patients aged ≥5 years receiving a standard second-line regimen for ≥6 months were recruited in three HIV outpatient-clinics supported by Médecins Sans Frontières in Kenya, Malawi and Mozambique. Viral load (VL) was quantified and resistance-genotyping performed if VL ≥500 HIV RNA copies/ml (virological failure). Sequences were interpreted with Stanford and ANRS algorithms. Virological failures are assessed 6 and 12 months after counseling or regimen change.

**Results:** 824 patients were included (median age 41 years, 45.4% males). In Kenya: among 355 participants (26.9 month median duration of second-line; 71.6% 3TC-TDF-LPV/r), 18.3% (65/355) had VL ≥500 copies/ml, 16.9% ≥1000 copies/ml. Among those aged ≤19 years, 31.2% (20/64) had ≥500 copies/ml. Overall 24.6% (16/65) had major PI-resistance, 72.3% major NRTI-resistance, 80% major NNRTI-resistance, and 9.2% major etravirine-resistance (Stanford). Nineteen patients (29.2%) required replacement of ineffective NRTIs, 21 (32.3%) needed to start a third line regimen (change of PI-component), with 3 children requiring pediatric formulations. Six months after regimen change 77.8% (14/18) had VL< 20 copies/ml. In Malawi: among 242 patients (36.3 month median duration of second-line; 81.4% 3TC-TDF-ATV/r), 16.5% had VL ≥500 copies/ml, 13.2% ≥1000. Among those aged ≤19 years, 29.4% (10/34) had VL≥500. Sequencing (37/40) detected 2.9% major PI-resistance, 78.4% major NRTI-resistance, 83.8% major NNRTI-resistance, 18.9% major etravirine-resistance. Seven patients required switch to a third-line regimen, 12 required NRTI-replacement. Complete resistance and regimen data will be available from all sites, including Mozambique (227 patients, 91.2% TDF-3TC-LPV/r).

**Conclusions:** These findings indicate good virological suppression in patients receiving second-line ART. Failure rates were notably higher among children and adolescents, highlighting the need for enhanced monitoring. Resistance data were essential to inform optimal regimen choice. Preliminary results indicate good short-term outcomes of patients who needed ART change. Increased access to resistance genotyping and affordable salvage ARVs, including pediatric formulations, are needed.

## TUPDB0105

### EFFECT OF PI RESISTANCE MUTATIONS ON VIRAL LOAD IN PATIENTS ON PI MONOTHERAPY

J.A. Thompson[1], C. Kityo[2], A.S. Walker[1], J. Hakim[3], A. Kambugu[4], J.J. van Oosterhout[5], A. Siika[6], A. Mweemba[7], P. Van den Eede[8], D.T. Dunn[1], N.I. Paton[1], for the EARNEST Trial Team

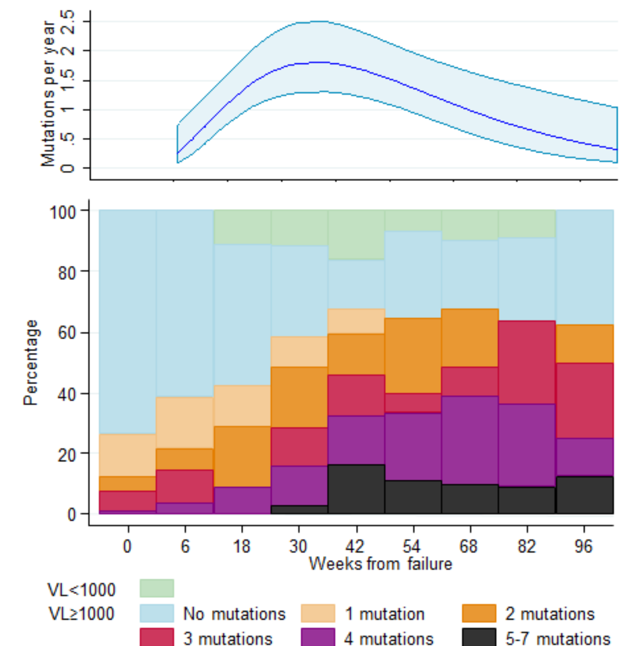
*[1]University College London, MRC Clinical Trials Unit, London, United Kingdom, [2]Joint Clinical Research Centre, Kampala, Uganda, [3]University of Zimbabwe, Clinical Research Centre, Harare, Zimbabwe, [4]Infectious Disease Institute, Kampala, Uganda, [5]University of Malawi, Blantyre, Malawi, [6]Moi University, Clinical Research Centre, Eldoret, Kenya, [7]University Teaching Hospital, Lusaka, Zambia, [8]Janssen, Beerse, Belgium*

*Presenting author email: jennifer.thompson@ucl.ac.uk*

**Background:** Protease inhibitor (PI) resistance mutations are uncommon in patients failing boosted-PI (bPI) containing regimens; longitudinal data assessing impact of PI resistance on outcomes are sparse.

**Methods:** We assessed the development of PI-resistance mutations over time in patients failing first-line NNRTI-based regimens and randomised within the EARNEST trial to bPI-monotherapy (standardised to lopinavir/ritonavir bd, with 12-week raltegravir induction to induce rapid VL suppression). VLs and resistance tests were performed blinded. Resistance testing was done retrospectively in one laboratory on all stored samples (12-16 weekly) between first confirmed virological failure (VL>1000 copies/ml) and switch to combination therapy.

**Results:** 405 patients started bPI-monotherapy and had ≥1 follow-up VL sample. Median treatment duration was 108(IQR 98-124) weeks until switch to combination therapy following an interim review. 148(37%) developed virological failure on bPI-monotherapy. Median VL at bPI-monotherapy failure was 3681c/ml, subsequently increasing by 0.48$\log_{10}$c/ml per year (95% CI 0.31-0.65). 28(26%) of the 106 with genotypes at bPI-monotherapy failure had major/minor PI mutations, increasing to 5(62%) of the 8 with genotypes 96 weeks after failure. The most common mutations were V82A(39%), I54V(39%) and M46I(32%). Rate of emergence of new mutations peaked at 37 weeks after failure (1.81 mutations /year; 95% CI 1.31-2.51; see figure). In a multivariable model, each new mutation was associated with a mean increase of 0.12$\log_{10}$c/ml(95% CI 0.06-0.18, p< 0.001). Q58E and I47A were associated with significantly (p< 0.02) larger increases of 0.74(95% CI 0.24-1.20) and 1.02(95% CI 0.47-1.56) log10c/ml respectively. I47A slowed the increase in VL by 0.43$\log_{10}$c/ml per year(95% CI -0.01-0.87, p=0.05).



*[Graph of rate to mutation development after failure and percentage of patients with each number of mutations after failure]*

**Conclusions:** Overall, the rate of accumulation of PI resistance mutations was slow in patients with virological failure on bPI monotherapy with lopinavir/ritronavir; declines after 37 weeks of failure suggest fitness costs may prevent additional mutations developing. The impact of resistance on VL is also limited, although I47A/Q58E appear to have greater effects.

### DOLUTEGRAVIR PLUS RILPIVIRINE IN SUPPRESSED HEAVILY PRE-TREATED HIV-INFECTED PATIENTS

A. Díaz[1], J.L. Casado[1], F. Dronda[1], C. Gómez-Ayerbe[1], M.J. Vivancos[1], S. Bañón[1], C. Quereda[1], S. Serrano[1], A. Moreno[1], E. Navas[1], M.Á. Rodríguez[2], M.J. Pérez-Elías[1], S. Moreno[1]
*[1]Ramon y Cajal University Hospital, Infectious Diseases, Madrid, Spain, [2]Ramon y Cajal University Hospital, Hospital Pharmacy, Madrid, Spain*
*Presenting author email: smguillen@salud.madrid.org*

**Background:** Patients with previous multiple virological failures are frequently suppressed with complex, toxic regimens. We aimed to explore the role of dolutegravir (DTG) 50 mg plus rilpivirine (RPV) 25 mg once daily in fully suppressed patients with a history of repeated treatment failures.
**Methods:** Ongoing cohort study. Heavily pretreated patients with multiple virological failures and resistance mutations who were on complex suppressive therapy were switched to a QD dual regimen with DTG + RPV. Patients were excluded if resistance to integrase inhibitors (INI) or RPV was shown. Follow-up visits were scheduled at 4, 12, 24 and 36 weeks after switching. The main outcome variable was persistence of undetectable HIV RNA.
**Results:** We included 38 subjects. At study entry, median age was 53.4 years, 34% were women, 68% were prior IDU, 70% were HCV-positive, and 34% had AIDS. Median nadir and current CD4+ cell count were 179 and 592 cells/mm3, respectively. Patients had received ART for a median 19.4 years with exposure to a median 3.6 drug families (100% NRTI, 89.5% NNRTI, 97.4% PI, 61.7% INI, 10.5% T20, 10.5% CCR5 receptor antagonist; 87% NRTI+NNRTI+PI, 52.6% NRTI+NNRTI+PI+INI). Previous failures were documented to one or more regimens including NRTI (100%), PI (71%), NNRTI (68.4%), and INI (8.1%). Patients with primary ART mutations were**:** 64.7% to NRTI**,** 37% to NNRTI, and 31.6% to PI. No INI-associated mutations were detected. Median time of undetectable HIV RNA load with current regimens was 6.7 years. Patients were taking a median 4.3 pills before switching. Only 1/38 (2.6%) patients left the study due to gastrointestinal toxicity, and another one because of DDI with omeprazole. HIV-RNA remained below 37copies/mL in 100% (38/38) at week 4, and 97% (33/34) at week 24. CD4 count kept stable after switching (median 633cells/$mm^3$ at week 24). We observed a statistically improvement in triglycerides and liver tests, with no changes in total, HDL and LDL-cholesterol. CKD-EPI eGFR decreased from 85 to 74 mL/min/1.73m² (95% CI 5.1-16.6, $p$=0.0002) at week 24.
**Conclusions:** Switching to a simple, dual regimen of DTG plus RPV in heavily pretreated, multiply failed, suppressed HIV-infected patients is safe and highly efficacious.

## TUPDC01 MEASURING PROGRESS TOWARDS 90-90-90

## TUPDC0101

### ACHIEVING UNAIDS 90-90-90 TARGETS IN A HIGH HIV BURDEN DISTRICT IN KWAZULU-NATAL, SOUTH AFRICA

A. Grobler[1], A. Kharsany[1], C. Cawood[2], D. Khanyile[3], A. Puren[4], L. Madurai[5]
*[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]Epicentre AIDs Risk Management (Pty) Limited, Pietermaritzburg, South Africa, [3]Epicentre AIDs Risk Management (Pty) Limited, Pietermartitzburg, South Africa, [4]Centre for HIV and STIs, National Institute for Communicable Diseases, National Health Laboratory Service (NICD/NHLS), Johannesburg, South Africa, [5]Global Clinical and Virology Laboratory, Amanzimtoti, South Africa*

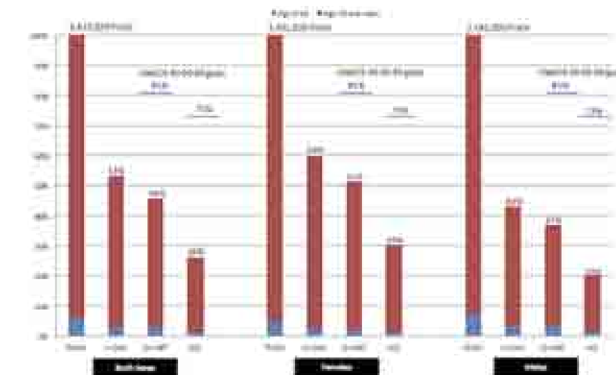
**Background:** With the goal of eliminating new HIV infections, the Joint United Nations Programme on HIV/AIDS (UNAIDS) set ambitious 90-90-90 targets to be achieved by 2020. Including 90% of people living with HIV knowing their HIV-status, 90% of these receiving antiretroviral therapy (ART) and 90% of these having viral suppression. Delivery of medical care to HIV-positive individuals requires a sequence of diagnostic tests, assessments and monitoring, termed the 'HIV treatment cascade'. The aim of this analysis is to quantify the current achievement and gaps in this cascade for participants enrolled in the HIV Incidence Provincial Surveillance System (HIPSS) in South Africa.
**Methods:** HIPSS is a household survey of HIV-prevalence and incidence in the uMgungundlovu District in KwaZulu-Natal in 2014 and 2015. Households within selected enumeration areas were randomly selected and a single randomly selected eligible (15-49 years) individual was invited to completed a questionnaire and provide blood samples for HIV-antibody and viral load testing.
**Results:** A total of 9812 participants, 3547(36.1%) males and 6265(63.9%) females was enrolled. HIV prevalence was 28.0%(95%CI:25.9-30.1) among males and 44.1%(95%CI:42.3-45.9) among females. First 90: 51.8% (95%CI: 47.4-56.3) of males and 64.6% (95%CI: 61.9-67.3) of females who are HIV positive knew their HIV status, p< 0.001. Second 90: 69.1% (95%CI: 63.4-74.9) of males and 70.3% (95% CI: 67.6-73.0) of females who knew their HIV status were on ART. Third 90: 85.5% (95% CI: 80.1-90.1) of males and 89.7% (95%CI: 87.3-92.0) of females on ART had suppressed viral load
(< 1000 copies/mL). Among all HIV positive participants 44.1% of males and 58.2% of females had suppressed viral load. More than 80% of both males and females who have not tested for HIV reported that they did not test for HIV because they were afraid to know their results.
**Conclusions:** All three elements of UNAIDS 90-90-90 targets were below 90%. The gap was largest for the first 90, especially amongst men where only half knew their status. Campaigns to increase HIV-testing are needed and reduce fear, especially amongst men. The target best accomplished is achieving suppressed viral load on ART; highlighting the success of ART in achieving viral suppression, if accessed.

## TUPDC0102

### ANALYSIS OF AGE- AND SEX-SPECIFIC HIV CARE CASCADES IN SOUTH AFRICA SUGGESTS UNEQUAL PROGRESS TOWARDS UNAIDS 90-90-90 TREATMENT TARGETS

W.B. MacLeod[1,2,3], N. Fraser[4], J. Bor[1,2,3], Z. Shubber[4], S. Carmona[5], Y. Pillay[6], M. Gorgens[4]
*[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Boston University School of Public Health, Department of Global Health, Boston, United States, [3]Center for Global Health and Development, Boston University School of Public Health, Bostn, United States, [4]World Bank, Washington, DC, United States, [5]University of the Witwatersrand, Department of Haematology and Molecular Medicine, Faculty of Medical Sciences, Johannesburg, South Africa, [6]National Department of Health, Pretoria, South Africa*
*Presenting author email: wmacleod@bu.edu*

**Background:** South Africa has adopted UNAIDS' treatment targets of 90% of people living with HIV (PLHIV) tested for HIV, 90% of those tested on antiretroviral treatment (ART), and 90% of those on ART having a suppressed HIV RNA viral load (VL). Using innovative record linkage techniques, we constructed HIV Care Cascades (HCC) to measure progress to these targets.
**Methods:** We defined the HCC for April 2014-March 2015 using four categories:
1) PLHIV,
2) engaged in HIV care,
3) on ART, and 4) virally suppressed.
PLHIV numbers were estimated using population size and HIV prevalence data from StatsSA and the Human Sciences Research Council. Numbers engaged in care were calculated as the number of individual patients with a CD4 count or viral load during this period, as assessed in newly-deduplicated data from the National Health Laboratory Service. Patients on ART were reported from District Health Information System. Persons with a VL test result <400 copies/ml were considered suppressed.
**Results:** Figure 1 shows HCC by sex and age group. Overall there were an estimated 6.47 million PLHIV (61% female, 6% aged <15 years), of whom 53% were in care, 46% on ART and 26% VL suppressed. An estimated 3.02 million PLHIV are either not yet diagnosed with HIV or diagnosed but not engaged in HIV care. Men and children aged <15 years fared worse across the cascade.



*[Figure 1. South African HIV Care Cascade by Sex and Age Group, April 2014 to March 2015]*

**Conclusions:** Large gaps remain across the HCC in South Africa, particularly those engaged in HIV care. In order to meet the 90-90-90 treatment targets, 73% of PLHIV in South Africa need to be virologically suppressed (far higher than the current 26%). Increasing the testing and initiation of those newly diagnosed on ART will have the largest impact on meeting these targets. Excellent monitoring data linking patients to their laboratory results are essential.

### CROSS-SECTIONAL ESTIMATES OF HIV INCIDENCE REMAIN HIGH IN RURAL COMMUNITIES IN BOTSWANA IN THE ERA OF SUCCESSFUL SCALE UP OF ART

S. Moyo[1,2], T. Mohammed[1], K.P. Kotokwe[1], C. Boleo[1], L. Mupfumi[1], S. Gaseitsiwe[1], R.M. Musonda[1], K. Bennett[3], E. van Widenfelt[1], T. Gaolathe[1], M. Mmalane[1], M.P. Holme[1,4], N. Khan[5], R. Wang[6,7], K. Wirth[4,8], E.J. Tchetgen Tchetgen[6,8], S. Lockman[1,4,9], J.M. Makhema[1,4], M. Essex[1,4], V. Novitsky[1,4]

*[1]Botswana Harvard AIDS Institute (BHP), Gaborone, Botswana, [2]University of Stellenbosch, Division of Medical Virology, Faculty of Medicine & Health Sciences, Tygerberg, South Africa, [3]Bennett Statistical Consulting Inc, Ballston Lake, NY, United States, [4]Harvard T.H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [5]Massachusetts General Hospital, Departments of Medicine and Pediatrics, Boston, United States, [6]Harvard T.H. Chan School of Public Health, Department of Biostatistics, Boston, United States, [7]Brigham and Women's Hospital, Departments of Medicine and Neurology, Boston, United States, [8]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [9]Brigham and Women's Hospital, Department of Medicine, Division of Infectious Diseases, Boston, United States*

*Presenting author email: sikhulilemoyo@gmail.com*

**Background:** The successful scale up of the national ART program in Botswana has almost reached the UNAIDS "90-90-90" goal (Gaolathe et al., CROI-2016). Cross-sectional estimate of HIV incidence needs to take into account ARV use to avoid mis-classification of HIV recency.

**Methods:** Using cross-sectional sampling HIV recency was estimated at the baseline of the Botswana Combination Prevention Project in 30 rural communities from Nov 2013 to Nov 2015. The algorithm for estimation of HIV recency combined Limiting-Antigen Avidity Assay (LAg) data, ART status and HIV-1 RNA load (as described in Rehle et al., *PLoS One* 2015;10:e0133255). The LAg cut-off normalized optical density was 1.5. ART status was documented. The HIV-1 RNA cut-off was 400 cps/mL. The Mean Duration of Recent Infection was 130 days and the False Recent Rate was zero.

**Results:** During the baseline household survey, a total of 3,596 individuals tested HIV positive among 12,570 individuals with definitive HIV status. Among those testing HIV positive, 3585 (99.7%) had a research blood draw available, of whom 3580 (99.9%) had LAg data generated. Of those, 326 were identified as LAg-recent cases. Among those, 278 individuals were considered chronically infected based on their documented ART status. Among the remaining 48 ART-naïve individuals, 14 had an HIV-1 RNA load ≤400 cps/mL. The Botswana MoH electronic medical records system was queried for these 14, 10 were found in the MoH data and evidence for initiation of ART was found for 5 individuals. ARV-naïve status could not be confirmed in 9 individuals. Thus, 34 LAg-recent, ARV-naïve individuals with HIV-1 RNA above 400 cps/mL were classified as individuals with recent HIV infections. HIV incidence was estimated at 1.06% (95% CI 0.70%-1.42%). Including 9 virologically suppressed individuals with uncertain ART status brings the estimate of HIV incidence to 1.34% (95% CI 0.91%-1.77%).

**Conclusions:** Using an algorithm including LAg-Avidity EIA, documented ART status and HIV-1 RNA load, cross-sectional HIV incidence in 30 rural communities in Botswana was estimated at 1.06%-1.34% in 2013-2015. Given the high level of ART scale-up in Botswana, studies able to identify HIV transmission sources and reduce HIV incidence are warranted.

### HOW CLOSE TO 90-90-90? MEASURING UNDIAGNOSED HIV INFECTION, ART USE AND VIRAL SUPPRESSION IN A COMMUNITY-BASED SAMPLE FROM NAMIBIA'S HIGHEST PREVALENCE REGION

T. Nakanyala[1], S.V. Patel[2], S. Sawadogo[3], A.D. Maher[4], K.M. Banda[1], A. Wolkon[3], S. Chaturvedi[5], P. Luphala[1], A.M.-A. Agovi[3], M.R. Chipadze[6], C. Ntema[6], D. Prybylski[3], I. Mabuku[7], D.W. Lowrance[8], N. Hamunime[1], S. Agolory[3], W. McFarland[5]

*[1]Ministry of Health and Social Services, Directorate for Special Programs, Windhoek, Namibia, [2]U.S. Centers for Disease Control and Prevention, Division of Global HIV and AIDS, Atlanta, United States, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and AIDS, Windhoek, Namibia, [4]University of California San Francisco California, Global Health Sciences, Windhoek, Namibia, [5]University of California San Francisco California, Global Health Sciences, San Francisco, United States, [6]Development Aid People to People, Total Control of the Epidemic, Zambezi, Namibia, [7]Ministry of Health and Social Services, Directorate for Special Programs, Zambezi, Namibia, [8]U.S. Centers for Disease Control and Prevention, Division of Global HIV and AIDS, Port-au-Prince, Haiti*

*Presenting author email: nakanyalat@nacop.net*

**Background:** Data on the continuum of HIV care are necessary to track progress in the response to the epidemic; however, they are difficult to obtain, particularly at a sub-national level. We directly measured HIV diagnosis, receipt of ART, and viral suppression in a community-based sample of adults in Zambezi, the region of highest HIV prevalence in Namibia.

**Methods:** A cross-sectional, household-based survey was conducted from 12/2014 - 7/2015 in five purposefully selected sites of Namibia's Zambezi region. Adults received HIV rapid testing using the national algorithm, completed behavioral interviews, and submitted dried blood spots (DBS) in their homes. Previous HIV diagnosis and receipt of ART within the past 90 days were measured through self-report and verified in patient-carried records when available. HIV-RNA viral load was quantified using DBS (Abbott Real-Time HIV-1 m2000 platform). Multivariable logistic regression was used to characterize disparities in outcomes.

**Results:** We enrolled 2,163 adults, of whom 1,312 [60.7% (95%CI: 58.6-62.7)] were female and 461 [21.3% (95%CI: 19.6-23.1) were HIV-positive. Among HIV-positives, 293 [63.6% (95%CI: 59.0-68.0)] were previously diagnosed. Among those diagnosed, 242 [82.6% (95%CI: 77.8-86.8)] were receiving ART. Of 209 DBS tested from participants receiving ART, 170 [81.3% (95%CI: 75.4-86.4)] were virally suppressed (i.e., < 1000 copies/uL), which equates to 36.9% (95%CI: 32.5-41.5) viral suppression among all HIV-positive adults. HIV diagnosis was significantly lower among men [Adjusted odds ratio (AOR): 0.24, $P$< 0.001] and youth (< 25 years) (AOR: 0.15, P=0.02). Receipt of ART was somewhat lower among rural residents (AOR: 0.33, $P$=0.08). Viral suppression was significantly lower among youth (< 25 years) (AOR: 0.27, $P$=0.002).

**Conclusions:** With 83% of previously diagnosed adults receiving ART and 81% of those on ART achieving viral suppression, the second and third benchmarks of the UNAIDS "90-90-90" targets are within reach for adults in Zambezi region. However, serostatus awareness among HIV-positive adults was well below the 90% target, especially among men and youth. Thus, overall prevention impact may be limited with only 37% of HIV-positive adults having unsuppressed virus. If the population-level prevention benefits of ART are to be maximized, "test and start" policies must be strengthened with new interventions to improve serostatus awareness.

## TUPDC0105

### ASSESSMENT OF THE IMPACT OF EARLY ART ON SEXUAL BEHAVIOUR IN INSIGHT STRATEGIC TIMING OF ANTIRETROVIRAL TREATMENT (START) TRIAL

A. Rodger[1], F. Lampe[1], W. Burman[2], A. Gruhlich[3], G. Friedland[4], W. El-Sadr[5], J. Neaton[6], S. Emery[3], G. Corbelli[7], J.M. Molina[8], C. Orkin[9], J. Gatell[10], J. Gerstoft[11], K. Ruxrungtham[12], M. Barbosa de Souza[13], A. Phillips[1], for the International Network for Strategic Initiatives in Global HIV Trials (INSIGHT) START Study Group

*[1]University College London, Research Department of Infection, London, United Kingdom, [2]University of Colorado, Denver, United States, [3]Kirby Institute, Sydney, Australia, [4]Yale University School of Medicine, New Haven, United States, [5]Columbia University, New York, United States, [6]University of Minnesota, Minnesota, United States, [7]European AIDS Treatment Group, Bruxelles, Belgium, [8]Université de Paris Diderot, Paris, France, [9]Barts Health NHS Trust, London, United Kingdom, [10]University of Barcelona, Barcelona, Spain, [11]Copenhagen University Hospital, Copenhagen, Denmark, [12]Chulalongkorn University, Bangkok, Thailand, [13]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil*

*Presenting author email: alison.rodger@ucl.ac.uk*

**Background:** Antiretroviral treatment (ART) reduces HIV infectiousness, but effect on sexual behaviour is unclear. The effect of early versus deferred ART on condomless sex was assessed in the START trial.

**Methods:** HIV+ people with CD4>500 mm$^3$ were enrolled from 35 countries (April 2009 to December 2013) and randomised to immediate or deferred (CD4< 350 cells/mm$^3$) ART. A sexual behaviour questionnaire was completed at baseline, 4, 12 and 24 months. Three risk measures were used:

(i) all condomless sex (CLS)

(ii) condomless sex with HIV negative (or unknown status) partners (CLS-D)

(iii) HIV transmission risk sex defined as CLS-D and not on ART for ≥6 months *or* viral load (VL) >200c/mL *or* no VL within 6 months (CLS-D-HIV-risk). The pre-planned primary outcome was CLS-D at month 12, with separate analyses for men-who-have-sex-with-men (MSM) and heterosexuals.

**Results:** 4685 HIV+ participants were randomised; 2620 (55.9%) MSM; 808 (17.3%) heterosexual men and 1257 (26.8%) women. Recruitment region: 33% Europe/Israel; 25% Latin America; 21% Africa; 11% N America; 8% Asia; 3% Oceania. Median (IQR) age 36 years (29, 44); 45% reported White, 30% Black and 14% Hispanic ethnicity.

17% (764/4605) reported CLS-D at baseline (MSM [20%], heterosexuals [13%]). Among MSM, there was no difference in CLS-D prevalence at month 12 or month 24. Among heterosexuals, at month 12, CLS-D prevalence was 11% in the immediate arm vs 8% in the deferred arm (p=0.066) and at month 24, 10% vs 6% (p=0.004). In both MSM and heterosexuals, CLS-D-HIV-risk was substantially lower in the immediate vs deferred arms at months 12 and 24 due to VL suppression on ART.

| *See Methods for definitions of (i) CLS, (ii) CLS-D (iii) CLS-D-HIV-risk. P values by chi-squared tests | MSM Immediate ART (N=1314 | MSM Deferred ART (N=1306) | P Value | Heterosexual Immediate ART (N=1012) | Heterosexual Deferred ART (N=1053) | P Value |
|---|---|---|---|---|---|---|
| Baseline CLS* | 427/1090 (39.2%) | 429/1094 (39.2%) | | 239/914 (26.1%) | 253/941 (26.9%) | |
| 12 months CLS | 359/1201 (29.9%) | 367/1148 (32.0%) | 0.28 | 177/909 (19.5%) | 195/931 (20.9%) | 0.43 |
| 24 months CLS | 357/1062 (33.6%) | 349/1032 (33.8%) | 0.92 | 153/719 (21.3%) | 110/714 (15.4%) | 0.004 |
| Baseline CLS-D* | 253/1281 (19.8%) | 257/1283 (20.0%) | | 132/1002 (13.2%) | 122/1039 (11.7%) | |
| 12 months CLS-D | 156/1232 (12.7%) | 155/1185 (13.1%) | 0.76 | 101/933 (10.8%) | 80/959 (8.3%) | 0.066 |
| 24 months CLS-D | 173/1064 (16.3%) | 152/1035 (14.7%) | 0.32 | 69/724 (9.5%) | 40/720 (5.6%) | 0.004 |
| Baseline CLS-D-HIV-risk* | 253/1281 (19.8%) | 257/1283 (20.0%) | | 132/1002 (13.2%) | 122/1039 (11.7%) | |
| 12 months CLS-D-HIV-risk | 3/1232 (0.2%) | 130/1185 (11.0%) | <0.001 | 6/933 (0.6%) | 74/959 (7.7%) | <0.001 |
| 24 months CLS-D-HIV-risk | 6/1064 (0.6%) | 97/1035 (9.4%) | <0.001 | 6/724 (0.8%) | 33/720 (4.6%) | <0.001 |

*[Table 1: Sexual behaviour at baseline, 12 and 24 months in the START Trial: comparison of immediate ART vs Deferred ART in MSM and heterosexuals]*

**Conclusions:** While no difference in condomless sex with sero-different partners (CLS-D) was noted between immediate vs deferred arms among MSM at 12 or 24 months, among heterosexuals there was evidence of higher levels of CLS-D in immediate vs deferred.

## TUPDC0106

### ANALYSIS OF THE EFFECTIVENESS OF THE OI/ART PROGRAMME IN HWANGE DISTRICT, MATEBELELAND NORTH PROVINCE, ZIMBABWE: LESSONS LEARNED FROM VIRAL LOAD ROLL-OUT PROGRAMME

N. Masuka[1], T.P. Goverwa-Sibanda[2], T. Maphosa[3], E.S. Tshuma[4], W. Kurauone[5], K. Ngarivume[6], T. Masungo[7], R.W. Carroll[8], P. Greiger-Zanlungo[9], G. Blick[10]
*[1]Ministry of Health and Child Care, Provincial Medical Director, Bulawayo, Zimbabwe, [2]Ministry of Health and Child Welfare, Provinicial Maternal and Child Health Officer, Bulawayo, Zimbabwe, [3]Ministry of Health and Child Care, Provincal STI/HV Coordinator, Bulawayo, Zimbabwe, [4]Ministry of Health and Child Care, Bulawayo, Zimbabwe, [5]Ministry of Health and Child Care, District Medical Officer, Victoria Falls, Zimbabwe, [6]BEAT AIDS Project Zimbabwe, Medical Director, Victoria Falls, Zimbabwe, [7]BEAT AIDS Project Zimbabwe, Laboratory Scientist, Victoria Falls, Zimbabwe, [8]World Health Clinicians, Inc, Outreach and Testing Coordinator, Norwalk, United States, [9]Montefiore Mount Vernon Hospital, Mount Vernon, United States, [10]World Health Clinicians, Inc, Chief Medical Officer, Norwalk, United States*
*Presenting author email: tpgoverwa@gmail.com*

**Background:** Hwange district(HD) is one of the districts with a high HIV burden in Zimbabwe(ZIM) with a prevalence of 18% against a national prevalence of 14.9%. In HD, 11,661(96%) adults and 622(81%) children were receiving ART through the public health sector by end 2015. The need to monitor such a large cohort of patients becomes very important with the country's adoption of the "90-90-90" commitment. Despite the adoption of viral load(VL) as gold standard to monitor patients on ART in Dec 2013, VL testing in ZIM is still very low, having achieved 3% in 2014. This was even lower in Hwange district. The Ministry of Health and Child Care began a nationwide VL Roll-Out Programme in June 2015.
**Methods:** The district received a TaqMan96 VL analyzer through partner support and 2408 routine VL tests were performed through December 2015. This is higher than what has been achieved in most rural districts in Zimbabwe. We analysed the VL results dataset to assess OI/ART program performance in relation to achieving the third "90".
**Results:** 2409 VL results were analysed of which 759 (63%) were female and 424 (37%) were male. The median age was 40 (IQR: 33, 48). 1170(99%) were on ART and, of these, 90% were on ART for more than 12mos. Viral suppression (VL< 1000) was achieved in 82.7% (86% of females,79% males; p=0.006). 57% of those below 20 years of age compared to 85% of those above 20 were virally suppressed (p=0.001). There were no statistically significant differences between patients followed-up through outreach into the rural communities (81.2%) and at the municipal hospital (83.1%) (p=0.31).
Mean PCR was 45,119c/mL (median 19; IQR: 0, 83); Mean log PCR 1.37 (median 1.28; IQR: 0,1.92). 18% on ART had PCR>1000c/mL (14%>10,000; 7%>100,000).

**Conclusions:** Routine VL testing to be done on all patients on treatment and follow-up to be made on all patients who were not virally suppressed. There is need to capacitate the program to conduct Drug Resistance testing for failing patients. Special focus and close monitoring needs to be placed on adherence support for adolescents and young adults to improve adherence to treatment.

# TUPDD01 HUMAN RIGHTS, WRONGS AND REALITIES: TRANSLATING FRAMEWORKS INTO ACTIONS

## TUPDD0101

### A RIGHT TO PREVENTATIVE CARE IN PRISONS: MOTIVATING PRISONERS' ACCESS TO CONDOMS IN SOUTHERN AFRICA

A. Raw
*Southern Africa Litigation Centre, Health Rights Programme, Johannesburg, South Africa*
*Presenting author email: annabelr@salc.org.za*

**Background:** Despite high levels of HIV transmission in prisons and the southern Africa region's disproportionate share of the global HIV burden, South Africa and Lesotho are the only two countries in the region in which condoms are, in policy at least, made accessible to prisoners. Criminal sanctions against consensual same-sex sexual acts in many jurisdictions and prohibitions on sexual contact amongst prisoners are often cited as legal impediments to policy change on the issue.
**Methods:** The paper analyses statutory frameworks and jurisprudence in selected jurisdictions in the southern Africa region where condom access is refused to prisoners. A legal argument is developed to establish that prisoners have a right to preventative care which includes access to condoms, irrespective of criminal provisions outlawing consensual same-sex sexual acts or legal restrictions on sexual contact in prisons.
**Results:** Prisoners have a legal right to access preventative care interventions and prison authorities are legally obliged to prevent the spread of disease in prisons. By applying a "doctrine of double effect" to the position of prison health authorities who distribute preventative measures such as condoms, the fulfilment of this obligation is legally justified irrespective of criminal sanctions or administrative prohibitions against sexual contact between prison inmates.
**Conclusions:** Advocacy to advance prison health services in southern Africa, through ensuring access to condoms and other measures to prevent the sexual transmission of HIV between prisoners, can be strengthened by legal arguments within existing legal frameworks. While criminal sanctions against consensual same-sex sexual acts ought to be challenged as infringing human rights protections and harming public health imperatives in their own right, motivating access to preventative care for prisoners need not necessarily be reliant in legal argument on the reform of those laws. Supporting advocacy initiatives within the existing legal frameworks may assist in countering popular justifications cited as legal impediments to making HIV prevention methods accessible in prisons.

## TUPDD0102

### "MMANGWANA O TSHWARA THIPA KABOHALENG" - THE MOTHER OF A CHILD HOLDS THE KNIFE ON THE SHARPER EDGE: IMPROVING HEALTH OUTCOMES FOR CHILDREN OF SEX WORKERS

I. Lakhani[1], D. Dlamini[2]
*[1]Sex Worker Education and Advocacy Taskforce, Advocacy and Human Rights Defence, Cape Town, South Africa, [2]Sisonke National Sex Worker Movement of South Africa, Advocacy and Human Rights Defence, Cape Town, South Africa*
*Presenting author email: dudud@sweat.org.za*

**Background:** "Children of sex workers deserve the right to education, health and safety, the government should respect my job and decriminalise sex work for my children's future" - Duduzile Dlamini, Sisonke Mobilizer and Mother's for the Future founder.
While sex workers enter the industry for numerous and complex reasons, one reoccurring theme that motivates many sex workers is children. A survey of 200 South African female sex workers by the Sex Workers Education and Advocacy and Taskforce found that those participating in the study were supporting 279 children in total. Studies have also shown incredibly high HIV prevalence rates among female sex workers in South Africa (ranging between 39.7% - 71.8%). What these studies show is that mothers whose primary source of income is sex work, are in a very precarious and extremely vulnerable situation. Not only is their work fully criminalised

Author Index

(they constantly face the threat of arrest and violence at the hands of the police), but the stigma and discrimination they face as sex workers greatly limits their ability to access health services for themselves and their children. It is in this context that "Mothers for the Future" (M4F) was founded in 2013.
**Description:** M4F is a programme that supports mothers who do sex work by providing a safe space as well as knowledge sharing, skills building, stigma reduction in addition to advocating for the decriminalisation of sex work.
**Lessons learned:** This programme illustrates that access to healthcare cannot be addressed in isolation from the broader social justice struggles. Through the use of a number of methodologies and tools M4F attempts to create integrated support that ranges from addressing urgent short-term needs such as accessing toiletries, medication, school fees etc and the more long term goal of law reform and decriminalising sex work. M4F is a powerful example of the efficacy of sex worker led interventions and how providing comprehensive support to mothers, can result in better overall health outcomes for their children.
**Conclusions/Next steps:** Creating better health outcomes for the children of sex works needs more than just a service delivery approach. Holistic support within a strong human rights framework is essential.

## TUPDD0103

### HUMAN RIGHTS AND ETHICAL DILEMMAS IN THE IMPLEMENTATION OF OPTION B+ IN MALAWI

A. Munthali[1], B. Chinsinga[1], J. Kadzandira[1], B. Ngwira[2], F. Masiye[3], B. Kaunda-Khangamwa[3]
*[1]University of Malawi, Centre for Social Research, Zomba, Malawi, [2]University of Malawi, The Polytechnic, Blantyre, Malawi, [3]University of Malawi, College of Medicine, Blantyre, Malawi*
*Presenting author email: amunthali@cc.ac.mw*

**Background:** Malawi pioneered Option B+ in July 2011. There have been concerns that with Option B+ pregnant and lactating women are forced to undergo HTC and start ART. The approach is also perceived as discriminatory as it offers ART only to women and not their spouses who may also be HIV+. Overall the delivery of Option B+ is perceived as a threat to patient rights concerning consent, confidentiality and counselling. This study explored people's perceptions about human rights and ethical issues surrounding the delivery of Option B+ in Malawi.
**Methods:** We collected data in 15 districts across Malawi. We conducted 18 key informant interviews at national level, 84 interviews with women on Option B+ and their spouses, 28 interviews with community leaders; 56 focus group discussions with community members,42 focus group discussions with women on Option B+ and 42 interviews with service providers. Content analysis was used to analyse the data.
**Results:** While some study participants viewed Option B+ as mandatory, hence breaching women's right to making decisions, most of them reported that women make their own decisions after appropriate counselling. Most study participants had no problems with the prioritization of pregnant and lactating women as it aimed at ensuring babies were born HIV uninfected. A few study participants, however, said that the procedure is ethically unfair as it does not offer ART to spouses who may also be HIV+ and this may cause strained relationships within the household. Lack of male involvement, fear of divorce, fear of stigma and discrimination and in some cases the low quality of counselling services constitute the most common barriers to Option B+ implementation.
**Conclusions:** There were a few participants who raised human rights and ethical issues surrounding implementation of Option B+. However the advantages of the program including improved health and ensuring children are born free of HIV outweigh the human rights and ethical concerns.

## TUPDD0104

### A RIGHTS-BASED APPROACH TO HIV, FAIR MIGRATION AND HEALTH: A GLOBAL FRAMEWORK FOR ACTION

A. Torriente[1], M. Licata[1], S. Mabhele[2]
*[1]International Labour Office (ILO), ILOAIDS, Geneva, Switzerland, [2]International Labour Office (ILO), ILOAIDS, Pretoria, South Africa*
*Presenting author email: torriente@ilo.org*

**Background:** The ILO estimates that there are 232 million migrant workers worldwide - 48 % are women. Many face obstacles that place their health at risk and heighten their vulnerability to HIV.
To reduce migrants' HIV risk it is essential to ensure their equal access to health services in countries of origin, transit and destination.
Migration alone is not a risk factor for HIV, but factors associated with migration are. These include discrimination, poor living/working conditions, sexual violence during migration and unfair migration practices.
**Description:** The ILO has developed a Framework Guidance Document to promote engagement and support contributions of all partner organisations to the new UNAIDS Strategy 2016-17 in the areas of migration and mobility.
The Framework contains four key elements:
- Analysis of new/emerging trends and developments around labour migration and associated HIV vulnerabilities
- Analysis of gender-specific dimensions of migration and their impact on HIV, health and migration policies
- Overview of international human rights law guiding guide labour migration governance and its interaction with health and social protection.
- Overview and examples of good practices around HIV and health programmes for migrants across countries/regions
The end result is a global framework for action which includes:
1) recommendations and evidence-informed guidance on integrating access to HIV and health services into labour migration processes at all stages of migration; and
2) roles/ responsibilities of national stakeholders on policy making and programme implementation around HIV and health issues in the context of migration.
**Lessons learned:** A fair labour migration agenda must address health deficits experienced by migrants in countries of origin, transit and destination. Bilateral agreements and migration policies and programmes should thus integrate health service access for migrant workers.
**Conclusions/Next steps:** Based on the Framework, the ILO will seek to engage organisations working on migration and HIV in coordinated efforts to:
· guide development and implementation of rights-based programmatic and policy responses integrating fair labour migration practices that increase migrants' access to health services, and
· guide national stakeholders in integrating HIV and health programmes for migrant workers into national migration policies and bilateral agreements.

## TUPDD0105

### IMPLEMENTING A HUMAN RIGHTS MONITORING AND RESPONSE SYSTEM (REACT) IN BURUNDI

A. Virga[1], C. Nininahazwe[2], N. Ndayizeye[3], J.D. Kabanga[4], The Link Up project
*[1]International HIV/AIDS Alliance, Brighton, United Kingdom, [2]RNJ+ (Burundi's National Network of Young People Living with HIV), Bujumbura, Burundi, [3]Humure, Bujumbura, Burundi, [4]Alliance Burundaise contre le SIDA (ABS), Bujumbura, Burundi*
*Presenting author email: avirga@aidsalliance.org*

**Background:** Link Up is a four year project funded by the Dutch government aimed at improving the sexual and reproductive health of young people from key populations in Bangladesh, Burundi, Ethiopia, Myanmar and Uganda. Rights-Evidence-Action (REAct), is a human rights monitoring and response system developed by the International HIV/AIDS Alliance to help provide evidence for human rights programming in Link Up.
**Description:** Alliance Burundaise contre le SIDA (ABS) has trained two of its implementing partners - RNJ+ (young people living with HIV) and Humure (LGBTI association) - on REAct. REAct is a community-driven system, which community-based organisations use to document human rights-related barriers in accessing HIV and health services and human rights violations. Information collected through interviews is used to provide individual responses to violations and to inform human rights-based HIV programming.
ABS, RNJ+ and Humure will be implementing REAct in Burundi's fragile and conflict affected context. The Burundi team is already aware of many cases of physical violence and discrimination faced by young people living with HIV and the LGBT and sex work communities when accessing HIV and SRHR services.
**Lessons learned:**
· It was important to develop customised questionnaires in French, specific to people living with HIV, LGBTI and sex workers in Burundi
· Young people living with HIV and young LGBT people are well-placed to administer the questionnaires and respond to clients› immediate needs because of their regular contact with clients
· Rights violations identified by implementing organisations in preparation for the documentation of cases through REAct include refusal to provide post-abortion care (abortion is highly restricted); discrimination of children living with HIV in schools; refusal to treat MSM in healthcare facilities; breach of confidentiality in healthcare settings; and failure to obtain clients› informed consent to receive services
**Conclusions/Next steps:** Collecting evidence of human rights violations is an essential step in advocating for law reform and policies to address violence and discrimination against young people from key populations. It is possible to document human rights violations in conflict affected countries; and ensuring the safety and security needs of interviewers and interviewees is a critical part of the training for the project.

## TUPDD0106

### REMOVING HUMAN RIGHTS BARRIERS TO EVIDENCE-BASED HIV PREVENTION, CARE AND TREATMENT: WHAT DO WE KNOW?

A. Stangl[1], D. Singh[1], M. Windle[2], K. Sievwright[1], K. Footer[2], A. Iovita[3], S. Mukasa[1], S. Baral[2]
*[1]International Center for Research on Women, Global Health, Washington, DC, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Joint United Nations Programme on HIV/AIDS, Geneva, Switzerland*
*Presenting author email: astangl@icrw.org*

**Background:** Repressive legal environments and widespread human rights violations act as structural impediments to efforts to engage key populations at risk of HIV infection in HIV prevention, care, and treatment efforts. The identification of human rights programmes and rights-based interventions that enable coverage of and retention in evidence-based HIV prevention and treatment approaches is crucial for achieving an AIDS-free generation.
**Methods:** We conducted a systematic review of studies that assessed the effectiveness of human rights interventions on improving HIV-related outcomes between 1/1/2003-28/3/2015. A comprehensive and systematic search protocol was iteratively developed including databases for both peer-reviewed and non-peer-reviewed reports. Ancestry searches for articles included in the review were also conducted.
Studies of any design that sought to evaluate an intervention falling into one of the following key human rights programme areas defined by UNAIDS were included with independent and dual-data abstraction at all stages: HIV-related legal services; monitoring & reforming laws, policies, and regulations; legal literacy programs; sensitization of lawmakers & law enforcement agents; and training for health care providers on human rights and medical ethics related to HIV.
**Results:** Of 31,861 peer-reviewed articles and reports identified, 24 were included in our review representing 15 different populations across 14 countries. The majority of studies incorporated two or more of the principles of the human rights-based approach, most often non-discrimination and accountability, and sought to influence two or more elements of the right to health, namely availability and acceptability. Half of the interventions addressed multiple UNAIDS' key programme areas, with monitoring and reforming laws and sensitizing law makers the most common. However, most interventions targeted a single socio-ecological level, namely public policy. Outcome measures varied considerably, making comparisons between studies difficult, and only a few studies explicitly referenced the promotion and protection of human rights.
**Conclusions:** The majority of studies reported a positive influence of human rights interventions on HIV-related outcomes. Yet, limited financial support for methodologically sound evaluations of human rights interventions limits the generalizability of these findings. Fast-tracking HIV prevention and expanding treatment approaches to achieve sufficient coverage will require effective structural interventions implemented in coordination with biomedical approaches.

## TUPDD0107LB

### IMPACT OF CLOSING SPACE FOR CIVIL SOCIETY ON LGBT GROUPS IN KYRGYZSTAN, INDONESIA, KENYA, AND HUNGARY

S.L.M. Davis[1], M. Hart[2]
*[1]New York University, Center for Human Rights and Global Justice, New York, United States, [2]Global Philanthropy Project, New York, United States*
*Presenting author email: sara.meg.davis@gmail.com*

**Background:** In response to both the threat of terrorism and to growing populist pressure for transparency and government accountability, many countries are using new laws and tactics to restrict freedom of association and freedom of expression. The study by Global Philanthropy Project, a network of private foundations, aimed to assess the specific impact of civil society restrictions on LGBT groups through four case studies.
**Methods:** Kyrgyzstan, Indonesia, Kenya and Hungary were selected as representative of trends in the four regions of Central Asia, Southeast Asia, East Africa and Europe. Over two months, researchers conducted desk review, as well as guided interviews with 19 LGBT activists, scholars, human rights experts and UN officials from the four countries.
**Results:** The report finds that while the four contexts had key differences, overall LGBT groups have always faced restrictions. In recent years a combination of new "LGBT propaganda" laws, resurgent nationalism, religious fundamentalism, and political scapegoating of LGBT people as "foreign agents" promoting "foreign values", together combine to heighten the risk environment to individuals and groups. LGBT groups are also forming new alliances and developing innovative approaches to continue their work.
**Conclusions:** UN partners and donors should monitor ways that closing space for civil society impacts on LGBT groups, which are critical as partners, watchdogs and HIV service providers; and should support LGBT alliance-building and advocacy to resist closing space.

# TUPDD02 WHATSUP: MOBILE TECHNOLOGIES, MULTIMEDIA AND MASS COMMUNICATIONS

## TUPDD0201

### A HACKATHON FOR HIV AND STD PREVENTION: USING MOBILE TECHNOLOGIES TO EXPAND ACCESS TO INFORMATION AND HIV PREVENTION, TESTING AND CARE SERVICES AMONG YOUNG KEY POPULATIONS IN BRAZIL

C. Euzébio de Lima[1], D. De Castro[1], M. Elizabeth de Lima Pereira[2], D. Ferreira Santana[2], P. Aguiar[2]
*[1]UNAIDS, Brasilia, Brazil, [2]Brazilian Association of Companies for the Sensual and Erotic Market (ABEME), São Paulo, Brazil*
*Presenting author email: euzebiodelimac@unaids.org*

**Background:** Brazil already counts on more mobiles than inhabitants: over 269 million active mobile phone lines in the country. More than 40% of young people in Brazil (aged 18-24) report mobile phone as most used device to access internet. The Brazilian Association of Companies for the Sensual and Erotic Market and UNAIDS have joined forces to promote the 1st Hackathon on HIV and STD Prevention, aiming to develop innovative mobile apps and games that can support the expansion of access to information and health services among young people - a vulnerable group that has been facing significant increase on HIV infection rates in the past 10 years.
**Description:** A hackathon is a digital marathon that gathers several different professionals involved in software programming including IT programmers, designers, communication professionals, entrepreneurs and others interested in technology. The Hackathon on HIV and STD Prevention was developed in two phases: 1) Information sessions (TED-Talk style meetings were carried out with the participation of specialists from health sector, sexuality, entrepreneurs and technology professionals, presenting different perspectives and opportunities in the market to the teams participating to the Hackathon; 2) Technology Marathon - 24 hour event for the development of apps/games and for the selection of best projects. Mentorship for the IT teams was provided by young MSM and young people living with HIV and health professionals (including UNAIDS technical advisers) to guarantee that the projects developed were based on real needs in prevention and human rights.
**Lessons learned:** The use of IT tools open up a world of new possibilities to promote HIV prevention and care especially with young key populations. Bringing together young IT professionals with young MSM and PLHIV is fundamental to the development of innovative projects that are feasible, attractive and with cutting-edge and appropriate language.
**Conclusions/Next steps:** Mobile apps market assessment needs to be taken into consideration given the huge number of free mobile apps/games competing for the attention of young audiences. The partnership with the erotic market is innovative and fruitful and represents an enormous potential to eroticize safe sex and to support the reinvention and update of HIV prevention messages.

## TUPDD0202

### *'ONCE YOU START WATCHING THIS SHOW, INTERSEXIONS, IT'S EASIER TO GET TO THE POINT THAT YOU REALLY WANT TO TALK'*: HOW VIEWERS' IDENTIFICATION WITH *INTERSEXIONS II* FACILITATED NEW COMMUNICATIVE SPACES

L. Myers[1], H. Hajiyiannis[2], T. Motuba[2], R. Delate[3], L. Mahlasela[3]
*[1]Centre for AIDS Development, Research and Evaluation, Cape Town, South Africa, [2]Centre for AIDS Development, Research and Evaluation, Johannesburg, South Africa, [3]Centre for Communication Impact, Pretoria, South Africa*
*Presenting author email: laura.myers@hiv-research.org.za*

**Background:** The successful South African television drama series, *Intersexions,* consisted of 26 interlinked episodes. While *Intersexions I* portrayed the risks of multiple and concurrent partnerships by mapping a fictional sexual network, *Intersexions II* (2013) portrayed how keeping secrets can increase risk of HIV infection through what is left unsaid or hidden in one's personal and sexual relationships.
**Methods:** A qualitative post-broadcast evaluation consisting of 14 focus groups and 12 interviews was conducted in six provinces with 122 regular viewers of the series. Participants needed to have watched at least half the episodes and reflected

Author Index

a mix of urban, peri-urban and rural localities. Discussions were audio-recorded, transcribed and analysed using NVivo.

**Results:** By portraying relevant and realistic themes, *Intersexions'* unusual dramatic formula succeeded in raising awareness about the influence of communication and the sexual network on HIV risk. Reported forms of interpersonal communication demonstrated that the drama series provided a useful tool to communicate sexual health content and life lessons with sexual partners, family and friends. Such conversations strengthened norms around open communication and greater critical consciousness about the limits of trust and the potential consequences of having sexual secrets. The episodes became more than *'just an episode'* in the way they prompted meaningful conversation and critical reflection about topics that were previously considered too taboo to comfortably discuss. Watching *Intersexions* thus spurred a new level of openness in a number of participants' family, peer and sexual relationships and for some, engagement with the series sparked meaningful self-reported behaviour change.

**Conclusions:** The power of mass media to create much needed spaces for interpersonal dialogue and conversation about sexuality, relationships, and HIV prevention is significant. Both *Intersexions* series appear to have broken through the silence and cultured *'HIV fatigue'* that often accompanies efforts to raise awareness about HIV prevention, care and support. By moving viewers beyond the simple *'ABCs'* of HIV prevention to asking critical questions about the quality of their relationships and the ways that communication and secrets in particular contribute to HIV risk, *Intersexions* may have contributed to a more complex and multifaceted shift in the national consciousness around HIV prevention.

## TUPDD0203

### DEVELOPMENT OF A MOBILE-BASED APPLICATION TO INCREASE UPTAKE OF HIV TESTING AMONG YOUNG U.S. MEN WHO HAVE SEX WITH MEN

K. Biello[1,2], J. Coffey-Esquivel[2], S. Hosek[3], M. Belzer[4], P. Sullivan[5], M. Mimiaga[1,2], S. Oleson[6], S. Taylor[6], L. Kreh[6], K. Mayer[2,7,8]

*[1]Brown University, Behavioral & Social Sciences and Epidemiology, Providence, United States, [2]Fenway Health, The Fenway Institute, Boston, United States, [3]Stroger Hospital of Cook County, Department of Psychiatry, Chicago, United States, [4]Childrens Hospital Los Angeles, Division of Adolescent Medicine, Los Angeles, United States, [5]Rollins School of Public Health, Epidemiology, Atlanta, United States, [6]Keymind, Falls Church, United States, [7]Harvard Medical School/Beth Israel Deaconess Medical Center, Division of Infectious Diseases, Boston, United States, [8]Harvard T. H. Chan School of Public Health, Global Health and Population, Boston, United States*

**Background:** Young men who have sex with men (YMSM) accounted for 72% of new HIV infections among all persons aged 13 to 24, and 30% of new infections among all MSM. However, overall rates of testing among young adults are suboptimal. Though mobile app use is nearly universal among US YMSM, there are currently no HIV prevention mobile phone apps developed specifically for YMSM, suggesting a need for further research to develop these interventions.

**Methods:** We conducted six focus groups with 33 participants (mean age=21.8, range 17-24; 36% Hispanic/Latino, 33% Black, non-Hispanic; 18% White, non-Hispanic, 12% other) in Boston, Chicago and Los Angeles. During focus group discussions, participants were shown an app developed to increase HIV testing for adult MSM, HealthMindr, and screenshots of potential adaptations, and provided feedback on the utility of the app, functionality of the various app features and how to best optimize the current app for use by young people prior to adaptation.

**Results:** Participants found the essential functions of the current app to be generally useful, including the ability to locate an HIV/STI testing site near them. They suggested adding the ability for the app to "ping" them when near a testing site and due for a test. Participants remarked that this would help overcome the obstacles associated with planning, such as forgetting to test, and would remove the responsibility of finding a testing location. While participants felt that the app contained an abundance of useful information and access to materials on HIV testing, PrEP and sexual health, they described the language and appearance as being very "medical" and unappealing to youth, suggesting changes to the interface, including use of avatars, infographics and less formal language.

**Conclusions:** Overall, participants liked the app and suggested that it would help them to increase the frequency and acceptance of HIV/STI testing and improve their general sexual health. However, suggestions for changes were provided. Further app development and testing is warranted.

## TUPDD0204

### CHARACTERISTICS OF BISEXUAL MEN WHO USE THE INTERNET TO SEEK SEX WITH OTHER MEN IN ONTARIO, CANADA

R. Souleymanov[1], D.J. Brennan[1], N. Lachowsky[1], S. Fantus[1], A. Ceranto[2]

*[1]University of Toronto, Faculty of Social Work, Toronto, Canada, [2]Fife House, Toronto, Canada*

*Presenting author email: rusty.souleymanov@mail.utoronto.ca*

**Background:** The use of the Internet to seek sexual partners is associated with increased HIV sexual risk behaviours for men who have sex with men (MSM). Little research, however, focuses specifically on bisexual MSM who use the Internet to seek sexual partners. In this analysis, we examined: 1) differences between bisexual and other-identified MSM with regard to HIV status, online sexual health outcomes, and condom use/non-use; 2) factors associated with condom use/non-use during the most recent anal intercourse for bisexual men.

**Methods:** Data were drawn from an online survey targeted at MSM in Ontario. Using logistic regression analysis and chi-square tests we assessed differences between bisexual-identified MSM and other-identified MSM (gay, queer) with regard to HIV status, online sexual health outcomes, and condom use/non-use. Following this, we used logistic regression to examine factors associated with condom use during the most recent anal intercourse for bisexual men. All results were considered significant at $p < .05$.

**Results:** The study included a total of 1830 MSM. Among these men, 438 (24.0%) indicated "bisexual" as their sexual orientation. Bisexual men were less likely than non-bisexual-identified men to be HIV-positive (2.4% versus 9.9%; OR=0.23, 95%CI:0.18-0.43), to have been recently tested for STIs (45.4% versus 65.3%; OR=0.44, 95%CI:0.35-0.55), and to receive sexual health information online (74% vs. 85.3%; OR=0.63, 95%CI: 0.47-0.85). Bisexual men were more likely than non-bisexual-identified men to report condom-use during their last male anal sex (65.7% versus 59.2%; OR=1.32, 95%CI:1.02-1.72). Substance use emerged as a significant factor associated with condom use during the most recent anal intercourse for bisexual men (OR=0.50, 95%CI:0.29-0.88).

**Conclusions:** Bisexual men who use the Internet to seek sex with other men may exhibit distinct sexual risk behaviours (decreased rates of STI testing, less sexual health information sought online, increased condom use) compared to other MSM. In addition, further research is needed to understand the link between condom use and substance use within the context of preventing HIV risk among bisexual men who use the Internet to seek sex with other men.

## TUPDD0205

### MASIVUKENI: A MULTIMEDIA ART INITIATION AND ADHERENCE INTERVENTION FOR RESOURCE-LIMITED SETTINGS

R.H. Remien[1], C.A. Mellins[1], R. Robbins[1], H. Gouse[2], C.S. Leu[1], J. Rowe[3], M. Henry[2], L. Myer[4], D. Stein[2], J. Joska[2]

*[1]Columbia University, New York State Psychiatric Institute, New York, United States, [2]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa, [3]Columbia University, Center for Teaching and Learning, New York, United States, [4]University of Cape Town, Department of Public Health and Family Medicine, Cape Town, South Africa*

*Presenting author email: rhr1@cumc.columbia.edu*

**Background:** The need for ART initiation and adherence with staggering numbers of people, and a reliance on lay counselors for ART counseling remain challenging in South Africa (SA) and globally. Masivukeni, a theoretically-derived behavioral intervention, was developed to enhance the capabilities of lay counselors to deliver ART adherence counseling to patients initiating ART. Masivukeni is a structured, laptop-based multimedia intervention requiring minimal training and supervision.

**Methods:** We conducted a randomised controlled trial of Masivukeni at two township clinics in Cape Town, SA. Masivukeni is consistent with standard of care counseling (SOC) guidelines (3-4 sessions prior to/ during ART initiation, follow-up sessions for defaulters, and inclusion of treatment support partners (buddies)). Masivukeni using videos, visually-relevant content, and interactive exercises that focus on key domains related to Social Action Theory (e.g., HIV/AIDS knowledge, motivation for health, mood, problem-solving skills, and social support). Patients eligible for ART-initiation who provided consent were allocated 2:1 to Masivukeni or SOC. Patients were seen 12-months post-initiation, corresponding with routine clinic-based viral load testing. Qualitative interviews with counselors were also conducted.

**Results:** Participants included 456 HIV+ adults with 337 (74%) completing 12-month follow-up; most patients lost to follow-up transferred out of the clinic or did not initiate treatment. At enrollment 20% had TB; 73% were female; mean age was 33 years; 42% had some employment; and 96% were impoverished (< R5000/month). At follow-up, over 90% of all patients (across study arms) achieved viral suppression (VL< 400copies/ml), however, proportionally, nearly twice as many SOC participants did not initiate ART compared to those in the Masuvkeni arm.. Among Masivukeni

participants, viral suppression was improved with increased buddy participation in counseling sessions. Counselors found the multimedia computerized intervention easy to use, enhancing their competence and confidence in their counseling role. They also reported greater patient learning and retention.
**Conclusions:** Masivukeni has promise as an adherence counseling tool, improving the numbers of patients who initiate treatment, and strengthening the work of and empowering counselors by standardizing and guiding their counseling interactions, providing visual aids solidifying patient understanding of HIV and its treatment, and contributing to rapid ART initiation and viral suppression.

## TUPDD0206

### "TÁNAMÃO" (INHAND) APP, A POCKET RISK CALCULATOR AND FREE PREVENTION SERVICE LOCATOR FOR CELL PHONES AND TABLETS

A. Mathias[1], L. Abreu[1], T. Zampieri[2], A. Spiassi[1], E. Gutierrez[1]
*[1]Programa Municipal de DST/AIDS de São Paulo, São Paulo, Brazil, [2]Centro de Testagem e Aconselhamento Henrique de Sousa Filho (CTA Henfil), São Paulo, Brazil*
*Presenting author email: amathiasbio@gmail.com*

**Background:** Recent data from epidemiological reports and surveys demonstrated increase of HIV infection, low use of condoms, and lack of awareness on the use of antiretroviral drugs among young population from Sao Paulo City. Furthermore, risk management and pre-exposure prophylaxis need to be publicized to encourage their adoption by this population.
**Description:** In order to address this problem, the STD/AIDS Program from the São Paulo City Department of Health commissioned a task force to create an app to provide accessible information in timely manner for young people. As a result, "TáNaMão" app (meaning "InHand" in English) was developed with the participation of representatives of key-populations. The user can input data and the app can calculate STD/HIV risk and provide guidance, and inform the nearest place to obtain free prevention supplies and healthcare.
**Lessons learned:** After successful test period with healthcare workers and key-population members, the app was released in social media, blogs and press. The app can be downloaded for Android and iOS. Noteworthy, Apple Store considers draws representing sexual interactions too explicit and blocks them.
**Conclusions/Next steps:** "TáNaMão" app was downloaded 3,660 times in six months after release, meaning that a broader promotion is required. A plan to increase app downloads through partnership with key people in online social networks and popular webpages is ongoing. A new version will have more friendly and enjoyable interface.

# TUPDD03 THE NEW NORMAL: SEXUAL IDENTITY, RELATIONSHIPS AND NORMS

## TUPDD0301

### DOES SEXUAL IDENTITY MATTER IN ACCESSING SERVICES?: RISK PROFILE AND HEALTH-SEEKING BEHAVIOURS OF DIFFERENT SEXUAL IDENTITY TYPES OF YOUNG MEN WHO HAVE SEX WITH MEN IN MYANMAR

W. Tun[1], P.P. Aung[2], A. Bajracharya[3], E. Yam[1], C. Ryan[2], S.M. Oo[4], Z.W. Thein[2], A.K. Paing[2], N. Pasricha[2], L. Willenberg[2], P. Agius[2], T.T. Sein[2], S. Htun[5], N.Z. Latt[4], S. Luchters[6]
*[1]Population Council, HIV and AIDS Program, Washington, United States, [2]Burnet Institute, Yangon, Myanmar, [3]Population Council, Phnom Penh, Cambodia, [4]HIV/AIDS Alliance, Yangon, Myanmar, [5]Marie Stopes International, Yangon, Myanmar, [6]Burnet Institute, Melbourne, Australia*
*Presenting author email: wtun@popcouncil.org*

**Background:** Men who have sex with men (MSM) are disproportionately affected by HIV compared to the general population in Myanmar (6.6% versus < 1%). While there is increasing information on risky behaviors of MSM in Myanmar, an in-depth understanding of how the risk profile and health-seeking behaviors differ by sexual self-identities is needed to tailor HIV/STI services. This analysis compares MSM with different sexual self-identities among young Myanmar MSM.
**Methods:** A behavioral cross-sectional survey was conducted in six townships in 2014 as a baseline for an evaluation of the Link Up project, a global consortium led by the International HIV/AIDS Alliance, to address sexual reproductive health needs of young key populations. Men (18-24 years) who had sex with a man in the previous six months were recruited using respondent-driven sampling to complete an interviewer-administered survey. Characteristics are compared using chi-squared test across different sexual identities: "tha-nge" (hidden MSM, insertive partner [*hidden/i*]), "apone" (hidden MSM, receptive partner [*hidden/r*]), and "apwint" (open MSM; typically receptive [*open/r*]).
**Results:** The study enrolled 623 MSM. Respondents self-identified as hidden/i (54%), hidden/r (16%), and open/r (29%). Open/r had the highest proportion reporting STI symptoms in the last 12 months (open/r: 37%; hidden/i: 23%; hidden/r: 24%; p< 0.01). All groups were equally likely to have sought STI treatment (57-65%). Open/r had the highest proportion ever having tested for HIV (open/r: 87%; hidden/i: 52%; hidden/r: 68%; p< 0.001); self-reported HIV-positivity was 15.7% (open/r), 1% (hidden/i), and 7% (hidden/r) (p< 0.001). While the majority of open/r and hidden/r (90-95%) revealed their male-male sexual behavior, only 78% of hidden/i revealed such (p< 0.001). Open/r were the most likely to have accessed an MSM-friendly drop-in center (open/r: 78%; hidden/r: 69%; hidden/i: 49%; p< 0.001) or been reached by a peer educator (open/r: 67%; hidden/r: 56%; hidden/i: 47%; p< 0.001).
**Conclusions:** Despite MSM being a vulnerable group overall, certain sexual identities of MSM may be even more vulnerable. The findings suggest the importance of tailoring MSM outreach and facility-based services to meet the nuanced needs of different sexual identities within MSM, particularly the hidden MSM who access services the least but are not without risk.

## TUPDD0302

### MEASURING GENDER NORMS AMONG VERY YOUNG ADOLESCENTS (AGES 10-14) AND YOUNG PEOPLE (AGES 15-24) IN UGANDA: TOOL VALIDITY AND ASSOCIATIONS WITH KEY HIV OUTCOMES

L. Vu[1], J. Pulerwitz[1], B. Zieman[1], J. Okal[2], E. Yam[1], Link Up Project
*[1]Population Council, HIV and AIDS Program, Washington, United States, [2]Population Council, HIV and AIDS Program, Nairobi, Kenya*
*Presenting author email: lung.vu@gmail.com*

**Background:** Gender norms are strongly associated with HIV-related factors, and they often form early in life. Very young adolescents (VYAs) ages 10-14 could benefit from gender transformative interventions, yet no tools are validated to measure gender norms among VYAs. The GEM Scale measures views towards gender norms, and has proven valuable in evaluating HIV programs for older adolescents/adults, in numerous settings. We assessed GEM Scale utility among Ugandan VYAs, and compared responses of VYA and older youth.
**Methods:** We conducted a two-stage cluster-sampled survey of 297 VYAs and 658 15-24 year-olds in rural and urban communities near Kampala. The survey included a 24-item GEM Scale. Using confirmatory factor analyses (CFA), we separately evaluated the scale among 10-14s and 15-24s. To maintain between-group comparability, we created a modified scale, omitting items with low CFA factor loadings (< 0.30). We trichotomized scores into low-, moderate-, and high-equitability groups, and assessed bivariate associations between gender-equitability and key outcomes.
**Results:** The GEM Scale proved an effective measure among both VYAs and older youth. For YVAs, CFA identified one latent construct with good fit [root-mean-square-of-error-approximation=0.04; Comparative-Fit-Index=0.93; Tucker-Lewis-Index=0.92], and consistency (α=0.74); 8 of the original items had low factor loadings. The 5 items with low factor loadings in both age groups were omitted to form the final 19-item scale. The scale results were comparable for males and females. Nearly 87% had low-to-moderate gender equitability. VYAs had lower mean scores than 15-24s (33.5 vs. 37.1; p< .0.001). VYAs were 3 times as likely to agree that "*a man should have the final word on decisions in his home*"(p< 0.001), or "*a woman who has sex before marriage does not deserve respect*" (p< 0.001). Analyses showed that gender equitable norms were significantly (p< 0.05) associated with key outcomes, including HIV knowledge, HIV testing, and condom use.
**Conclusions:** The GEM Scale provides a valid measure of gender norms across a wide age range, including VYAs, and is associated with important HIV outcomes. Moreover, support for equitable gender norms was generally low, and lower among VYAs compared to their older counterparts. This gap may provide opportunities for gender transformative interventions for VYAs.

### THE 'ONE MAN CAN' MODEL: COMMUNITY MOBILISATION AS AN APPROACH TO PROMOTE GENDER EQUALITY AND REDUCE HIV VULNERABILITY IN SOUTH AFRICA

A. Anderson[1], E. Stern[2], T. Mokganyetji[2], D. Rebombo[3], C. MacPhail[4], N. Khoza[5], S. Treves-Kagan[6], A. Selin[6], D. Peacock[7], A. Pettifor[8], S. Lippman[9], K. Kahn[10], R. Twine[10]
*[1]Sonke Gender Justice, Research, Monitoring and Evaluation, Cape Town, South Africa, [2]University of Cape Town, School of Public Health, Cape Town, South Africa, [3]Sonke Gender Justice, Community Education and Mobilization, Johannesburg, South Africa, [4]University of New England, Armidale, Australia, [5]Wits University, School of Public Health, Johannesburg, South Africa, [6]University of North Carolina Chapel Hill, Chapel Hill, United States, [7]Sonke Gender Justice, Cape Town, South Africa, [8]University of North Carolina Chapel Hill, Epidemiology, Chapel Hill, United States, [9]University of California, Epidemiology, San Francisco, United States, [10]MRC/Wits Rural Public Health and Health Transitions Research Unit, Agincourt, South Africa*
*Presenting author email: deanpeacock@gmail.com*

**Background:** Among other factors driving the HIV epidemic in Sub-Saharan Africa are social norms reinforcing restrictive gender roles and inequitable gender relationships. These limit women's ability to protect themselves from HIV, while simultaneously put social pressure on men to take on a range of sexual health risks. To understand the benefits of engaging men and boys for gender equality and HIV prevention, this study explored the impacts of Sonke Gender Justice's 'One Man Can' (OMC) community mobilisation approach in a multi-level HIV intervention. The study assessed whether OMC community mobilisation activities targeting young men could promote gender-equitable norms that decrease women's HIV vulnerability and men's HIV risk behavior in South Africa.
**Methods:** The OMC community mobilisation intervention evaluation was a randomized controlled trial implemented in Agincourt, rural northeast, South Africa between 2012 and 2014. Young men (18-35 years) were the primary targets for the intervention, which included workshops and innovative outreach activities on gender equality and health. This analysis draws from qualitative data collected from intervention implementers and community members at the last time point during the intervention. Directed content analysis was employed as an analytic approach.
**Results:** Our findings indicate significant attitudinal and some behavioral changes around gender equality and HIV risk amongst OMC intervention implementers and community members. At the interpersonal level, adoption of gender-equitable beliefs had positive effects of improved communication and a more balanced division of labor between intimate partners. At the community level, the results were mixed. OMC activities increased awareness and interest in reducing gender inequality and HIV risk. However, intervention implementers experienced some resistance from community leaders in providing training on aspects of gender equality, condom use, abortion rights, and homosexuality. HIV interventions that incorporate community mobilisation should explore avenues to actively engage local leaders in supporting shifts in norms around these issues.
**Conclusions:** Community mobilisation is potentially a powerful tool to promote equitable gender norms and build consciousness and action around HIV prevention. When men are mobilized to recognize how harmful gender norms negatively impact their lives, the changes they make towards improving their own health can have added benefits for the women in their lives.

## TUPDD0304

### SIMILAR AND DIFFERENT FACTORS ASSOCIATED WITH TRANSACTIONAL SEX WITH MAIN PARTNERS AND CASUAL SEXUAL PARTNERS IN YOUNG WOMEN IN URBAN INFORMAL SETTLEMENTS IN SOUTH AFRICA

A. Gibbs[1], N. Ntini[1], T. Khumalo[1], L. Washington[2], N. Mbatha[2], E. Chirwa[3], S. Willan[3], Y. Sikweyiya[3], N. Jama-Shai[3], R. Jewkes[3]
*[1]Health Economics and HIV/AIDS Research Division, Durban, South Africa, [2]Project Empower, Durban, South Africa, [3]Gender and Health Research Unit, Medical Research Council, Pretoria, South Africa*
*Presenting author email: gibbs@ukzn.ac.za*

**Background:** Transactional sex is a significant risk factor for HIV-acquisition amongst young women. Yet there may be significant variation in the forms of transactional sex with main partners and transactional sex with casual partners. Our study sought to describe the prevalence of each form of transactional sex and compare the risk factors for each amongst young women in urban informal settlements.
**Methods:** We drew on cross-sectional data from 320 women aged 18 to 38 in informal settlements in Durban, South Africa who comprised the control arm of a cluster randomised RCT. Primary outcomes were transactional sex with a main partner in the past 12m and transactional sex with a kwapheni (casual) partner in the past 12m, both assessed using 5 items. Other measures included socio-demographics, violence experienced and alcohol and drug use. We built Gaussian random effects regression models for each form of transactional sex.
**Results:** Women were young (mean ages 24.4 years). 61.1% (CI 52.1-69.5) reported transactional sex with a main partner in the past 12m and 49% (CI95%41.9-56.2) reported transactional sex in the past 12m with a kwapheni. There was significant overlap between both forms with 41.9% (CI9534.2-49.9) reporting both. Transactional sex with a main partner was significantly associated with being in a more controlling relationship (aOR1.07 p< 0.05), experiencing economic violence from an intimate partner in the past 12m (aOR2.29, p< 0.01), experiencing past year non-partner sexual violence (aOR1.86, p< 0.05) and women's greater alcohol use (aOR1.1 p=0.001). Transactional sex with a casual (kwapheni) partner was associated with greater hunger (aOR2.4, p< 0.05), experiencing economic violence from an intimate partner in the past 12m (aOR1.76, p< 0.05), experiencing non-partner sexual violence in the past 12m (aOR2.26, p< 0.01) and using drugs in the past year (aOR2.57, p< 0.0001).
**Conclusions:** Transactional sex with main partners and casual partners in this population is high. Risks associated with both forms of transactional sex emphasise the ways in which men's controlling behaviours and women's experiences of lack of economic autonomy shape women's engagement in transactional sex. Reducing both forms of transactional sex requires interventions to empower women, including their economic autonomy.

## TUPDD0305

### PAYING FOR SEX AND ASSOCIATED RISKS AMONG YOUNG MALE PAVEMENT DWELLERS IN DHAKA CITY, BANGLADESH

T. McClair[1], T. Hossain[2], N. Sultana[2], E. Yam[3], B. Zieman[3], S. Hossain[2], R. Yasmin[4], N. Sadiq[5]
*[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]Population Council, Dhaka, Bangladesh, [3]Population Council, Washington, United States, [4]Marie Stopes Bangladesh, Dhaka, Bangladesh, [5]International HIV/AIDS Alliance, Dhaka, Bangladesh*

**Background:** Dhaka City is home to thousands of migrants from Bangladesh's rural areas who live in the streets as "pavement dwellers." Bangladesh development programs often prioritize addressing girls' substantial health needs, but young males also have vulnerabilities. This study assesses their practice of paying for sex, and its association with HIV-related risks.
**Methods:** As part of the global Link Up project, trained interviewers recruited 447 male pavement dwellers from seven Dhaka City pavement dweller "hotspots." At each hotspot, interviewers used random selection techniques (like spinning a bottle) to invite males ages 15 to 24 to participate in a survey that covered HIV-related risks and behaviors. We conducted descriptive analysis to examine sociodemographic characteristics, paying for sex (giving money, goods, or services in exchange for sex in past year), sexually transmitted infection (STI) symptoms (past six months), and high-risk sex (unprotected last sex with non-primary partner). Among those who had ever had sex (N=321), we conducted multivariate logistic regression analysis to assess whether transactional sex was associated with STI symptoms or high-risk sex, controlling for sociodemographic characteristics and early sexual debut.
**Results:** Median participant age was 18 years, 7% completed education above primary school, and 98% reported earning any income, a median of US$76/month. Eighty-nine percent were never married and 4% were living with a parent/guardian. Seventy-two percent had ever had sex and 44% had early sexual debut (< age 15). Physical abuse was reported by 77% of participants and sexual abuse by 13%. Of those who had ever had sex, 80% had paid for sex, 52% engaged in high-risk sex, 79% had had symptoms consistent with STIs, and 3% had ever received an HIV test. In multivariate analysis, those who had paid for sex had significantly increased odds of reporting recent STI-related symptoms (adjusted odds ratio [AOR]=1.75, 95% confidence interval [CI]: 1.14-2.68), and had greater odds of engaging in high-risk sex (AOR=2.13, 95% CI: 1.48-3.08).
**Conclusions:** Young, pavement dwelling males in Dhaka City have unique vulnerabilities. The adverse factors associated with paying for sex highlight the need for targeted programs that promote condom use, STI screening/treatment, and HIV testing in this population.

## TUPDD0306

### LOVE WITH HIV: A LATENT CLASS ANALYSIS OF INTIMATE RELATIONSHIPS AMONG WOMEN LIVING WITH HIV ENROLLED IN CANADA'S LARGEST MULTISITE COMMUNITY-BASED RESEARCH STUDY

A. Carter[1,2], S. Greene[3], C. Hankins[4], L.A. Brotto[5], D. Money[5,6], M. Kestler[7], S. Patterson[1,2], N. O'Brien[8], K. Salters[1,2], E. Ding[1], K. Webster[2], V. Nicholson[2], M. Sanchez[9], M. Desbiens[10], D. Dubuc[8], S.Y. Lin[1,2], R.S. Hogg[1,2], A. de Pokomandy[8], M.R. Loutfy[10], A. Kaida[2], CHIWOS Research Team
*[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Simon Fraser University, Burnaby, Canada, [3]McMaster University, Hamilton, Canada, [4]University of Amsterdam, Amsterdam, Netherlands, [5]University of British Columbia, Department of Obstetrics and Gynecology, Faculty of Medicine, Canada, [6]BC Women's Hospital and Health Centre, Women's Health Research Institute, Vancouver, Canada, [7]University of British Columbia, Division of AIDS, Department of Medicine, Vancouver, Canada, [8]McGill University Health Centre, Montreal, Canada, [9]ViVA, Positive Living Society of BC, Vancouver, Canada, [10]Women's College Research Institute, Toronto, Canada*
*Presenting author email: allison_carter@sfu.ca*

**Background:** Quantitative studies traditionally reduce relationships to single-item variables and investigate sexual risk-taking. To broaden understanding of relationships and sexuality, we characterized types of intimate relationships among women living with HIV (WLWH) using multiple measures and examined differences in affection and associated psychosocial characteristics.
**Methods:** Using a critical feminist approach, we analyzed questionnaire data for 1,335 WLWH
(≥16 years) in the multi-site, community-based Canadian HIV Women's Sexual and Reproductive Health Cohort Study. We conducted latent class analysis, incorporating eight indicators: marital status, duration, sex with regular partner in past 6-months, physical intimacy, emotional closeness, relationship power, exclusivity, and couple HIV-serostatus. We assessed construct validity by examining prevalence of affection ('*Someone to love and make you feel wanted*'), and identified covariates using multinomial logistic regression.
**Results:** We delineated 5 latent classes: no relationship (47%), relationship without sex (9%), and three types of sexual relationships-short-term/casual (16%), long-term/unhappy (7%), and long-term/happy (22%). Women in the latter two classes had high probabilities of reporting an exclusive married/common-law/living-apart relationship of ≥3-years duration relative to women in short-term/casual relationships, yet they diverged on contentment with physical intimacy (44%-unhappy *vs.* 97%-happy), emotional closeness (24% *vs.* 86%), power (43% *vs.* 82%), and couple HIV-serodiscordance (59% *vs.* 71%). Affection was most prevalent in long-term/happy relationships (64%) and relationships without sex (48%), compared to long-term/unhappy (39%), short-term/casual (37%), and no relationship (23%) (p< 0.0001). Relative to no relationship: women >50-years were less likely to be in any relationship; women reporting sex work [AOR:3.03(95%CI:1.64,5.61)] and violence [6.64(3.33,13.26)] were more likely to be in short-term/casual relationships; women without depression [2.90(2.04,4.12)] were more likely to be in long-term/happy relationships. No differences by gender, sexual orientation, or ethnicity were observed.
**Conclusions:** Nearly half of Canadian WLWH were not in relationships. Women's relationships were heterogeneous, though HIV-serodiscordance was common and one-fifth reported long-term/happy and loving sexually active relationships. Sex, however, did not equate with affection, and relationships without sex had higher levels of love than some sexual relationships. A nuanced focus on promoting healthy relationships may offer a more comprehensive approach to supporting women's sexual well-being, particularly among older WLWH and those with experiences of sex work, violence, and depression.

## TUPDE01 QUALITY IMPROVEMENT: AIM HIGH

## TUPDE0102

### THE EFFECTIVENESS OF A QUALITY IMPROVEMENT COLLABORATIVE TO ACCELERATE ELIMINATION OF MOTHER TO CHILD TRANSMISSION (EMTCT): KEY OUTCOMES AND DETERMINANTS FROM A DEMONSTRATION PHASE COLLABORATIVE IMPLEMENTED IN SOUTH AFRICA, 2012 - 2015

A. Chirowodza[1], D. Williams[1], C. Diergaardt[1], O. Adetokunboh[1], S. Gede[2], N. Gobodo[2], N. Makeleni[2], N. Tuswa[2], M. Eckard[3], T. O'rie[4], N. Shingwenyana[1], B. Green[1], I. Oluwatimilehin[1]
*[1]South to South Programme for Comprehensive Family HIV Care and Treatment, Department of Paediatrics and Child Health, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [2]Amathole District, Department of Health, East London, South Africa, [3]Pixley ka Seme District, Department of Health, De Aar, South Africa, [4]Cape Winelands District, Department of Health, Worcester, South Africa*
*Presenting author email: admirec@sun.ac.za*

**Background:** South Africa has made substantial improvements in prevention of mother-to-child transmission (PMTCT) services in South Africa as demonstrated by a reduction in vertical transmission in the recent past. Challenges remain in health programme implementation for key antenatal and postnatal services.
We describe impact and determinants for successful implementation of a quality improvement collaborative (QIC) approach as a method to accelerate the achievements of elimination of mother-to-child transmissions (eMTCT) goals in South Africa.
**Methods:** In partnership with the Department of Health, we implemented a QIC in 55 health facilities in three provinces over two phases: a pilot phase and a demonstration phase. Learning sessions and quality improvement (QI) projects were conducted focusing on key elements of the PMTCT cascade. QI teams received coaching and on-site training. To assess performance, we compiled control charts using PMTCT indicators from district health information system. The Wilcoxon signed-ranks test was used to test for significance in increases or decreases between pre-post intervention medians. Influencing factors such as facility level QI skills, organisational culture and facility type and location were measured to understand influencing factors.
**Results:** We observed marked regional variation in improvement for early booking rates in 2 out of 3 provinces (24 % in the Eastern Cape; *p*< .001; 4% in the Western Cape). All sites improved antenatal HIV retest rates (Eastern Cape 31%; *p*< .001; 11% in the Northern Cape 11%; *p*< .001; Western Cape 74%; *p*< .001). Postnatal visit within 6 days rates improved (varying from 6%-15% in supported provinces). Exclusive breastfeeding rates improved (28% increase in the Eastern Cape; *p*< .001, 15%; in the Northern Cape; *p*< .001, 12% in the Western Cape; *p*< 001). The 18 month rapid test uptake rates improved for all provinces (Eastern Cape 28%; *p*< 0.001; 20%, Northern Cape 25%; *p*< 001 and Western Cape 25%; *p*< 001). Factors influencing performance were baseline rates, facility type and size, quality improvement skills, leadership and buy in for quality improvement.
**Conclusions:** The collaborative approach achieved rapid improvements in eMTCT program outcomes in a wide range of facilities across South Africa. Performance variability may be attributed to contextual, organizational and system factors.

## TUPDE0103

### CONTINUOUS QUALITY IMPROVEMENT FOR VOLUNTARY MALE MEDICAL CIRCUMCISION TRAINING: EXPERIENCES AND RESULTS FROM THE FIELD

D. Jacobs[1], R. Mabuse[2], T. Maartens[2], F. Dikgale[1], J. Sithole[2], A. Thambinayagam[3], J. Ndirangu[1]
*[1]University Research Co., LLC, Quality & Performance Institute, Pretoria, South Africa, [2]University Research Co., LLC, USAID ASSIST Project, Pretoria, South Africa, [3]USAID Southern Africa, Pretoria, South Africa*
*Presenting author email: raymondm@urc-sa.com*

**Background:** Continuous quality improvement (CQI) is a deliberate and a systematic process designed to intervene in issues of quality in voluntary medical male circumcision (VMMC) using 8 WHO quality standards. University Research Company (URC) conducted VMMC baseline assessment at 134 Department of health (DoH) facilities where implementing partners (IP's) are providing this service. Following this assessment, gaps were identified which revealed non-compliance of sites to different areas of WHO quality standards. URC saw the need to train those who manages this service at a programmatic level as well as those at site level to improve the quality of service provided as well as to reduce adverse events. A CQI training exercise empowers the providers not only to identify gaps and come up with improvement strategies but also to assess themselves, identify bottlenecks and shortfalls and improve going forward.

**Description:** MMC baseline assessment was conducted in 8 provinces: Mpumalanga (MP); Eastern Cape (EC); Gauteng (GP); Kwazulu Natal(KZN); Limpopo(LP); Northern Cape(NC) and North West(NW) to look at compliance of sites to WHO quality standards. Three days training was then conducted by URC staff to empower the providers so that they can provide good quality service. In total 279 healthcare workers were trained across the eight provinces. Post training 2 subsequent assessments were then conducted to assess improvement in the quality of service and compliance with the standards.
**Lessons learned:** Post CQI training results shows that provinces improved significantly on average from 76.4 %( baseline) to 92.8 %( reassessment). Individual provinces scored as follows: EC (81.4% to 96%), GP (78.2% to 97.3%), KZN (80.4% to 94.2%), LP (81.4% to 98.5%), MP (63.4% to 90.1%), NC (69.2% to 94.9%), NW (78.0% to 80.6%).
**Conclusions/Next steps:** CQI training has empowered those providing the MMC service with skills, knowledge, and understanding of the program to enable them to provide safe, high quality MMC service. Results after training showed that provinces improved significantly in their performance as far as providing quality service is concerned.

## TUPDE0104

### EFFECTS OF CONTINUOUS QUALITY IMPROVEMENT AS A TOOL FOR INSPIRATION AMONGST HEALTH CARE WORKERS AND HIV+ MOTHERS ON RATES OF HIV AND MALNUTRITION AMONGST HIV-EXPOSED INFANTS IN RURAL RWANDA

W. Leonard[1], D. Uwamahoro[1], T. Uwacu[1], A. Ishimwe[1], A. Mutaganzwa[2], E. Chang[3], J.D. Ngirabega[4]
*[1]The Ihangane Project, Aptos, United States, [2]Ruli District Hospital, Ruli, Rwanda, [3]University of California, Center for AIDS Research and Education, Los Angeles, United States, [4]East African Health and Research Commission, Arusha, Tanzania, United Republic of*
*Presenting author email: wendy@theihanganeproject.com*

**Background:** Frontline health care workers are most effective when they feel valued, capable, and optimistic about the future. The Ihangane Project and Ruli District Hospital, serving 200,000 people in the Northern Province of Rwanda, created a Continuous Quality Improvement (CQI) program that promotes these principles amongst health care workers and HIV+ mothers as a key strategy to increase adoption of Prevention of Mother To Child Transmission (PMTCT) protocols and ultimately eliminate mother to child HIV transmission and dramatically decrease malnutrition amongst HIV-exposed infants.
**Description:** Health care workers and HIV+ mothers at seven health centers associated with Ruli District Hospital designed and implemented a CQI program that builds trust, fosters capacity and utilizes trends to demonstrate linkages between care quality and durable good health outcomes. Our approach focuses on five pillars of quality care: Clinical Care, Mother-Centered Systems, Data Management, Logistics, and Health Education. Pillars are assessed using an Observational Check List (OCL) every four months, followed by a collaborative meeting to review results. Health care workers identify areas of strength and weakness in current practices and consider interventions for improvement. In collaboration with HIV+ mothers, they design and implement improvements in their system of care.
**Lessons learned:** From March 2013 through December 2015, 332 HIV-exposed infants and 302 HIV+ mothers enrolled in the health centers' PMTCT programs. Quality across all pillars of care increased by 118% (39% to 85%). Nurses' ability to accurately diagnose malnutrition increased by 74% (46% to 80%) and infant HIV testing at appropriate intervals increased by 800% (from 8% to 72%). Improvement in care quality contributed to a 66% (41% to 14%) decrease in acute (underweight) malnutrition and a 62% (61% to 23%) decrease in chronic (stunting) malnutrition amongst HIV-exposed infants, and a 63% (1.6% to 0.6%) decrease in the rate of mother-to-child HIV transmission.
**Conclusions/Next steps:** Good health outcomes are possible even in extremely resource-limited settings. A Continuous Quality Improvement program that enables health care workers and their patients to improve their systems of care and connects actions to good health outcomes is a cost-effective approach to building effective and resilient health systems that can reach and sustain health goals.

## TUPDE0105

### IMPROVING MALE PARTNER TESTING IN PMTCT: A QUALITY IMPROVEMENT INITIATIVE IN KINANGO HOSPITAL, KWALE COUNTY, KENYA

D. Mwakangalu[1], M. Nzaro[2], Y. Mwamzandi[3], B.S. Mwero[3], J. Makori[3], R. Mlongo[3], A. Bunu[2]
*[1]Pathfinder International, Mombasa, Kenya, [2]Pathfinder International, Nairobi, Kenya, [3]Kenya Ministy of Health-Kwale County, Nairobi, Kenya*

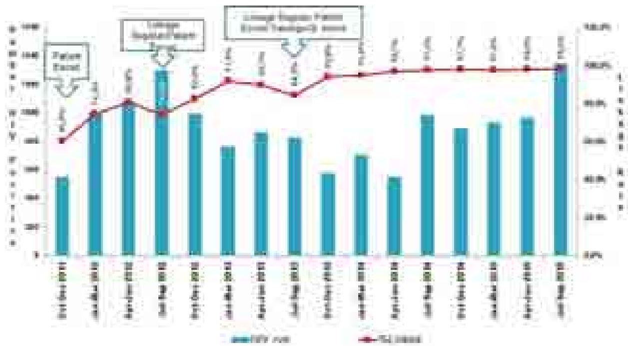
**Background:** HIV testing for pregnant women during the antenatal period has been successful across Kenya with 92% of ANC mothers having their HIV status determined (KAIS 2013). Despite this success, couple testing has remained low despite intensive health education. HIV-infected male partners with unknown HIV status pose a number of risks including infecting their HIV-negative pregnant partners and potentially increasing the risk of mother to child transmission. Testing couples together removes burden of disclosure from HIV-infected partners and improves adherence, retention in care, and enhanced partner support.
**Description:** To address low couples testing for HIV, the USAID-funded APHIAplus Nairobi-Coast project, led by Pathfinder International, supported Kinango Hospital's quality improvement team to conduct a root cause analysis and implement a quality improvement 'change idea' to improve couple testing at the hospital MCH Department. From August 2014, pregnant women who presented to the MCH were issued letters inviting their partners to accompany them to the facility for ANC visits. The project ensured community awareness of the initiative through mentions during morning health talks and individual counseling sessions. Male partners were offered rapid HIV testing as couples according to the national guidelines. Data was captured on routine MOH data collection tools.
**Lessons learned:** Pregnant women attending first ANC visit and who had their male partners tested for HIV increased from 4 (1%) between August 2013 and July 2014 to 336 (84%) between August 2014 and July 2015. A total of 39 pregnant women and 17 males tested positive and were provided assisted disclosure and enrolled in HIV care. Twenty-six of the 27 infants exposed to HIV tested negative through early infant diagnosis testing by DNA PCR. Seven mother-baby pairs were referred to other facilities and four were lost to follow-up.
**Conclusions/Next steps:** Couple testing for HIV can be successfully integrated with ANC visits by inviting partners to attend ANC visits. This approach can help improve uptake of HIV testing and counseling among male partners, help with disclosure, and improve MTCT rates. Using existing quality improvement teams, change ideas like this one can be successfully replicated.

## TUPDE0106

### INCREASING LINKAGE TO HIV CARE FOR NEWLY DIAGNOSED HIV-INFECTED PERSONS THROUGH QUALITY IMPROVEMENT APPROACH IN URBAN SLUMS IN KENYA

S. Kegoli[1], A. Njoroge[2], J. Motoku[3], C. Muriithi[4], I. Mutisya[5]
*[1]Eastern Deanery AIDS Relief Program, Prevention, Nairobi, Kenya, [2]Eastern Deanery AIDS Relief Program, Nairobi, Kenya, [3]Eastern Deanery AIDS Relief Program, Care and Treatment, Nairobi, Kenya, [4]Eastern Deanery AIDS Relief Program, HMIS, Nairobi, Kenya, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV/AIDS, Nairobi, Kenya*
*Presenting author email: yry1@cdc.gov*

**Background:** Kenya AIDS strategic framework targets to identify 90% of people living with HIV (PLHIV), provide treatment to 90% while ensure 90% on ART achieve virological suppression. Despite scale up HIV testing coverage, only 60% and 31% of PLHIV are linked to care and ART respectively. Pre-enrollment loss to follow-up and delayed linkage to care is associated with increased morbidity and mortality.
Eastern Deanery AIDS Relief Program has 14 facilities within 95 slums in Nairobi serving 2,157,690 people. Despite scaled up HIV testing in facilities and community, enrolment into care remained low necessitating innovative strategies to address the challenge. The program utilized the Kenya HIV Quality Improvement Framework guidance to improve linkages to care.
**Description:** A Continuous Quality improvement (CQI) activity was initiated involving Plan-Do-Study-Act (PDSA) cycles between Oct-2012 and Sep-2015. The goal was to improve linkage to care of newly diagnosed PLHIV from 60% to >95%. PDSA cycle results were reviewed quarterly and lessons learnt summarized, effective strategies retained and new ones adopted where necessary.
**Lessons learned:** PDSA cycle one in Oct-2012 involved use of patient escorts by counselors which led to increased linkage from 60% to 80.8% by June-2012. PDSA cycle two in Sept-2012 introduced linkage registers for counselors to track intra-facility linkages in addition to patient escorts and telephone calls and home visits for patients not linked on the testing day improved linkages from 74.2% to 91.8% by Mar-2013. PDSA cycle three in Oct-2013 and combined patient escorts, linkage register and training of counselors within quality improvement teams. At the end of PDSA cycle three, linkages improved and were sustained at 98% by Sept-2015.



[Graph 1: Trends of improved linkages to care of newly diagnosed HIV infected persons between Oct-2012 and Sept-2015]

**Conclusions/Next steps:** Successful Linkages to HIV care and treatment services may be achieved through adoption of multiple strategies that are feasible and affordable such as use of patient escort, improved HCW skills and use of linkage registers.

# POSTER EXHIBITION

## MECHANISMS OF ACTIVATION / INFLAMMATION AND IMPACT ON PATHOGENESIS

### TUPEA001

### RANTES, CD169/SIGLEC-1 AND CD38-HLADR ARE INDEPENDENTLY ASSOCIATED WITH CXCR4-TROPISM IN TREATMENT NAÏVE HIV-1 SUBTYPE C INFECTED INDIVIDUALS

B.J. Connell[1], L. Hermans[1,2], P.J. Schipper[1], P.M. van Ham[1], D. de Jong[1], S. Otto[3], K. Tesselaar[3], S.R. Moraba[1], W. de Jager[4], J. Borghans[3], M.A. Papathanasopoulos[5], W.D.F. Venter[6], H. Tempelman[2], A.M.J. Wensing[1], M. Nijhuis[1]
*[1]University Medical Centre Utrecht (UMCU), Department of Medical Microbiology, Utrecht, Netherlands, [2]Ndlovu Care Group, Limpopo Province, South Africa, [3]University Medical Centre Utrecht (UMCU), Department of Immunology, Laboratory of Translational Immunology, Utrecht, Netherlands, [4]University Medical Centre Utrecht (UMCU), Department of Pediatric Immunology, Laboratory of Translational Immunology and Multiplex Core Facility, Utrecht, Netherlands, [5]University of the Witwatersrand, Medical School, Johnnesburg, South Africa, [6]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa*
*Presenting author email: bibiconnell@gmail.com*

**Background:** Switch from CCR5 (R5) to CXCR4 (X4) co-receptor tropism of HIV-1 subtype B occurs in ±60% of untreated patients and is associated with rapid progression to AIDS. The etiology of this switch is largely unknown, however CD4+ T-cell activation (CD38-HLADR) has been shown to correlate with X4 tropism in HIV-1 subtype B. We investigated the prevalence of X4-tropism in a cross-sectional cohort of antiretroviral therapy (ART)-naïve South African HIV-1 subtype C infected individuals and hypothesized that X4-tropism was correlated with CD4+ T-cell activation, monocyte activation and plasma co-receptor ligand concentration.
**Methods:** One hundred HIV-1 subtype C infected ART-naïve patients, 18-45 years old were enrolled at a rural clinical site in South Africa. Plasma and peripheral blood mononuclear cells were isolated. Genotypic prediction of HIV-1 co-receptor usage was performed based on deep sequencing of the envelope region (gp120-V3) and interpretation with the $\text{geno2pheno}_{\text{co-receptor}}$ algorithm, using a False Positive Rate (FPR) of 3.5%. Cellular markers for T-cell activation and monocyte activation were measured using FACS and soluble leukocyte activation markers and coreceptor ligand concentrations were determined by Luminex xMAP technology.
**Results:** All viral isolates were sequenced successfully and 22% were predicted to be X4-tropic. In a univariate analysis X4-tropism was negatively associated with CD4 counts and positively associated with immune activation (i.e CD38-HLADR) in CD4 cells, CD169/Siglec-1 on monocytes and plasma RANTES levels (p< 0.05). When corrected for CD4 count, age and sex; RANTES, CD169/Siglec-1 and CD38-HLADR expression were independently predictive of X4-tropism in a multivariate analysis, but CD4 count itself was not identified as an independent predictor.
**Conclusions:** In this cohort of HIV-1 subtype C ART-naïve patients 22% harbor the X4 predicted virus. We detected higher levels of CD4 immune activation, plasma RANTES levels and CD169/Siglec-1 expression on monocytes, each independently associated with X4 tropism. CD169/Siglec-1 captures HIV-1 through recognition of the viral envelope glycan shield and transfers the virus through synaptic cell-cell contacts to uninfected cells. Our novel observations may impact the way we understand the transfer of X4-tropic cell-free virus to permissive lymphocytes. These data have important ramifications in the way we understand HIV-1 pathogenesis and tropism in HIV-1 subtype C infection.

### CD4+ T CELL ACTIVATION: A NEW LINK BETWEEN INTIMATE PARTNER VIOLENCE AND HIV RISK?

A. Kalokhe[1,2], C. Ibegbu[3], S. Kaur[3], M. Kelley[4], C. del Rio[1,2], R. Stephenson[2,5]
*[1]Emory University, School of Medicine, Division of Infectious Diseases, Atlanta, United States, [2]Emory University, Rollins School of Public Health, Department of Global Health, Atlanta, United States, [3]Emory University, School of Medicine, Department of Pathology and Laboratory Medicine, Atlanta, United States, [4]Emory University, Rollins School of Public Health, Department of Biostatistics and Bioinformatics, Atlanta, United States, [5]University of Michigan, School of Nursing, Department of Health Behavior and Biological Sciences, Ann Arbor, United States*
*Presenting author email: akalokh@emory.edu*

**Background:** Behavioral pathways linking intimate partner violence (IPV) experience to HIV are well-established, but the biologic pathways remain unexplored. We hypothesized that IPV-induced stress negatively affects HIV systemic immune defenses and aimed to evaluate whether IPV was associated with immune profiles established as harboring increased HIV risk: CD4 activation and decreased regulatory T cell (Treg) frequency.
**Methods:** From Feb-Nov 2014, demographics, past-year and lifetime IPV, child abuse, substance abuse, and post-traumatic stress disorder (PTSD) data were obtained from HIV-negative high-risk women. Blood, urine, and genital ulcer (if present) samples were collected for AM cortisol, immune assays, and STI testing. Frequencies of activated CD4 T-cells (%HLA-DR+/CD38+), Tregs (%CD4+CD25+FoxP3+) and phenotyping of CD4 (using CD27, CD45RA) were assessed by flow cytometry. Nonparametric tests evaluated the association between IPV, covariates (child abuse and demographics), and immune outcomes. Multivariate regression explored confounding of the IPV-CD4 relationship and moderation by cortisol, cocaine use, and PTSD.
**Results:** 75 HIV-negative high-risk women age 18-50 were enrolled. Lifetime IPV was associated with increased CD4 activation ($\rho$=0.331, p=.004), a shift in CD4 phenotype from naïve ($\rho$=-0.339, p=.003) to effector memory ($\rho$=0.367, p=.001), and an increase in activated Tregs (HLA-DR+/ CD45RA-, $\rho$=.260, p=.024), but not total Treg frequency. Past-year IPV was also associated with increased CD4 activation ($\rho$=0.257, p=.026) and had similar trends. After controlling for sexual IPV, the association between lifetime physical and psychological abuse and CD4 activation remained significant (β=.579, p=.004 and β=.362, p=.033, respectively). After controlling for race (the only covariate linked to increased activation), the lifetime IPV-CD4 activation link remained significant (β=.313, p=0.012). While PTSD was associated with increased CD4 activation ($\rho$=0.247, p=.034), neither PTSD, cocaine use, nor cortisol were moderators of the IPV-CD4 activation pathway.
**Conclusions:** Our data is the first to suggest a potential immune link between IPV and HIV and may help explain individual-level differences in HIV susceptibility and response to biologic HIV prevention strategies. The association of psychological and physical IPV with CD4 activation independent of sexual abuse (i.e. genital tract trauma) further supports the existence of a stress-induced immune pathway.

## MECHANISMS OF T CELL DEPLETION AND RECONSTITUTION

### TUPEA003

### THE EFFECT OF HIV-1 INFECTION ON S1P-R1 EXPRESSION AND FUNCTION IN THYMOCYTES AND THEIR PROGENITORS DURING ENTRY INTO AND EGRESS FROM THE HUMAN THYMUS

R. Resop[1], J. Craft[1], D. Vatakis[2], B. Blom[3], C. Uittenbogaart[1]
*[1]University of California, Microbiology, Immunology and Molecular Genetics, Los Angeles, United States, [2]University of California, Department of Medicine, Los Angeles, United States, [3]Amsterdam Medical Center, Amsterdam, Netherlands*
*Presenting author email: resopr@ucla.edu*

**Background:** Lack of T cell regeneration in HIV infected individuals is likely due to a defect in entry of hematopoietic stem cells (HSC) into, and egress of naïve T cells from, the thymus to the periphery. Limited work has been done to elucidate these phenomena. We studied the effect of HIV-1 infection on the receptors to Sphingosine-1-phosphate (S1P), a chemotactic sphingolipid mediator, during thymocyte trafficking. Our novel findings show that HIV changes expression of S1P Receptor 1 (S1P-R1) which is normally only expressed at the mRNA and protein level in mature CD3+CD69- thymocytes about to exit the thymus.
**Methods:** Using flow cytometry and qPCR we examined the dynamics of S1P-R1 expression on Hematopoietic Stem Cell (HSC) progenitors and thymocytes during HIV infection. Mice implanted with human fetal thymus/liver (HIS-mice) infected with CXCR4- or CCR5-tropic HIV-1 were injected intravenously with CFSE-labeled HSC to examine the effect of HIV on HSC entry, thymocyte development and egress.

We also investigated the mechanism of changes in S1P-R1 and its transcriptional regulator, Kruppel-Like factor 2 (KLF2).
**Results:** We found that S1P-R1 is expressed at low-moderate levels on human HSC. In infected HIS mice CFSE-labeled CD34+ progenitors developed into mature thymocytes in the human thymus/liver implant and a subset expressed S1P-R1, indicating that entry into the thymus and development are functional during early HIV infection. Surprisingly, we found that S1P-R1 and KLF2 were significantly upregulated in mature thymocytes post-HIV infection. Intriguingly, S1P-R1 was also upregulated by HIV within the CD3+CD69+ population, which normally does not express S1P-R1. S1P-R1 signaling as measured by pAkt was not impaired in infected thymocytes, which is in contrast to published data that S1P-R1 response in HIV infection may be impaired in other cell types.
Our results show that the mechanism of increased S1P-R1 in the thymus by HIV may be due to cytokines such as TNF-α which significantly increased S1P-R1 expression on thymocytes *in-vitro*. Additional cytokines perturbed during HIV infection are currently being tested.
**Conclusions:** S1P-R1 upregulation post-HIV-1 infection may offer insight into T cell reconstitution mechanisms during infection and provide potential alternate avenues for immunotherapy.

Sacco', Chair of Immunology, Milan, Italy, [3]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy, [4]Don C. Gnocchi Foundation IRCCS, Milan, Italy, [5]University of Milan Bicocca, Milan, Italy*
*Presenting author email: a.muscatello@asst-monza.it*

**Background:** Some severely immunodeficient HIV patients experience poor recovery of CD4+ T-cell counts on antiretroviral treatment (ART). Gammadelta (γδ) T cells play an important role in protective immunity in HIV-infection and alteration of γδ T-cell distribution in the peripheral blood is the earliest defect in cellular immunity after HIV infection. We analyzed γδ frequencies and activation in HIV-infected ART-naive patients and correlated these parameters with disease stage and immunological response to ART.
**Methods:** Retrospective, cohort study in HIV-patients receiving cART for at least 12 months that, prior to ART initiation, had cryopreserved PBMCs. Exclusion criteria: duration of cART < 12 months, failure to achieve virologic suppression after 12 months of cART, treatment with immunomodulatory drugs. Patients were classified as advanced naïve (AN) or less advanced naïve (LAN) if nadir CD4 T cell count was ≤200 or >200 cells/μL, respectively. Frequencies, phenotype and activation of γδ T cells were measured by FACS analysis on baseline cryopreserved PBMCs.
**Results:** Twenty-six patients [10 AN and 16 LAN, 24 males (92%), medians: age 43 years, absolute nadir CD4+ T cell count 280/ml, HIV-RNA 4.9 log10cp/ml] were enrolled. AN had higher prevalence of AIDS-defining illnesses (50% *vs.* 0%, p=0.004), lower nadir CD4+ T cells count [87 (IQR 49-141) cells/ml *vs.* 312 (IQR 276-380) cells/ml], lower CD4/CD8 ratio at presentation [0.10 (IQR 0.07-0.17) *vs* 0.34 (IQR 0.21-0.51)] and higher pre-ART HIV-RNA [5.66 (IQR 5.2-5.9) log10cp/ml *vs* 4.66 (IQR 4.35-4.93) log10cp/ml]. At baseline AN showed significantly higher frequencies of effector-memory (CD45RO+/CD27-/CD28-) subset of Vδ1+ T cells as compared to LAN (p=0.04). Change (%) in CD4+ T cell count after 12 months of ART was negatively correlated to frequencies of activated (CD38+ HLADR- and CD38+ HLADRII+) Vδ1+ CD8+ T cells (rho=-0.447, p=0.029 and rho=-0.533, p=0.005, respectively) and Vδ2+ CD8+ (rho=-0.379, p=0.05) T cells. A similar trend was also observed in cytolytic-like CD57+ Vδ1+ T cells (rho=-0.501, p=0.009).
**Conclusions:** Subsets of γδ T-cell are differently distributed in AN as compared to LAN patients. Increased activation of γδ T cells at baseline predict a worse immune reconstitution after suppressive ART.

## TUPEA005

### IMMUNOMETABOLIC ANALYSIS IDENTIFIES KEY ROLE OF HYPOXIA INDUCIBLE FACTOR-1 ALPHA (HIF-1α) IN HIV-INDUCED CD4+T CELL DEPLETION

G.A. Duette[1], J. Rubione[1], P. Pereyra Gerber[1], F. Erre Diaz[1], A. Varese[1], E. Dantas[1], A. Merlotti[1], C. Palmer[2], M. Ostrowski[1]
*[1]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA. UBA-CONICET, Buenos Aires, Argentina, [2]Burnet Institute, Melbourne, Australia*
*Presenting author email: gabriel.duette@gmail.com*

**Background:** In the absence of antiretroviral drugs, persistent HIV-1 infection causes dysfunction and progressive loss of CD4+ T cells, leading to the development of AIDS and ultimately to death. The pathogenic mechanism responsible for CD4+ T cell functional dysregulation and death are still unclear. In this study, we investigated the modulation of glucose metabolism by HIV-1 infection and its relationship with CD4+ T cell depletion.
**Methods:** CD4+ T cells from healthy donors were isolated from peripheral blood, activated in vitro and subsequently infected with HIV-1. At day 5 post-infection, cell viability was analyzed by Annexin V/7-AAD staining. Glucose metabolism was analyzed by quantifying glucose uptake and L-Lactic acid production. Hypoxia-inducible factor 1α (HIF-1α) activity was analyzed by different cellular and biochemical approaches.
**Results:** By using multi-parametric FACS analysis, we found that HIV-1 infection of purified activated blood CD4+T cells increases their glycolytic activity by stimulating the activity of the metabolic regulatory complex mTOR and the transcription factor HIF1α. The HIV-1-induced stimulation of aerobic glycolysis resulted in the intracellular accumulation of L-lactic acid and apoptosis, as detected by Annexin V/7-AAD staining. In vitro silencing of HIF-1α expression reduced L-lactate production induced by HIV-1 and prevented CD4+ T cell death.
**Conclusions:** In conclusion, we have established a novel mechanism by which HIV-1 promotes HIF-1α-mediated induction of aerobic glycolysis and L-Lactic acid production in CD4+ T cells, inducing cell death. Manipulation of glucose metabolism in CD4+ T cell could open a path to the development of a new class of therapy to improve immune reconstitution in treated HIV patients.

*Presenting author email: matteo.basilissi@gmail.com*

**Background:** Studies have described a protective role of CD8+ memory stem T cells (Tscm) in HIV disease progression and have shown a beneficial effect of long-term cART in restoring their frequency and function. Nonetheless, data on longitudinal modifications of this subset are lacking. We investigated the kinetics of CD4+ and CD8+ Tscm prior to and following cART aiming to understand their correlation with peripheral T-cell homeostasis/activation and gut function/microbial translocation, recognized markers of clinical outcome and response to treatment.
**Methods:** HIV-infected individuals were studied prior to (T0) and following 12 months of cART (T12). T-cell activation (HLA-DR+CD38+), maturation (CCR7, CD45RA), exhaustion (PD1) as well as subpopulations with a Tscm (CCR7+CD45RA+CD27+CD95+), Th17 (CCR6+CD161+) and gut-homing phenotype (CD4+CCR9+β7+) were studied. Microbial translocation (EndocAb, LPS) and gut function (CDh1, IFABP) markers were measured in plasma. Wilcoxon test and Spearman's correlation were used for statistics.
**Results:** 20 subjects were enrolled. In the course of cART, the decrease in activated CD4+ and CD8+ T-cells paralleled the contraction of exhausted naïve and CD8+ effector memory subsets. A reduction in gut-homing CD4+ and a rise in Th17 was also observed, yet no significant variation was seen in terms of microbial translocation and gut function. The CD4+ Tscm pool also decreased under treatment, while the CD8+ Tscm did not.
CD4+ Tscm positively correlated with Th17 (r=0.6, p=0.01) at T0 and with gut-homing CD4+ (r=0.5, p=0.02) at T12.
Prior to cART, the CD8+ Tscm compartment correlated with activated CD4+ (r=0.6, p=0.006) and Th17 (r=0.6, p=0.007).
**Conclusions:** The kinetics of CD4+ and CD8+ Tscm may differ in the first 12 months of cART, with a rapid contraction of CD4+ Tscm and stable CD8+ Tscm. Th17 subsets correlated with both Tscm CD4+ and Tscm CD8+ cells, suggesting a homeostatic link between these compartments prior to cART. Similarly, the reduction of peripheral CD4+ Tscm and gut-homing CD4+ as well as their positive correlation in the course of treatment, may imply migration of both populations to the gut. Finally, the positive correlation between CD8+ Tscm and activated CD4+ in cART-naïve subjects put forward a role of the former in the pathogenesis of HIV disease.

## CORRELATES AND BIOMARKERS OF CLINICAL PROGRESSION OF HIV INFECTION

### TUPEA007

### RESIDUAL INFLAMMATION AND ENDOTHELIAL ACTIVATION IN HIV-1 VERTICALLY INFECTED CHILDREN WITH FULLY SUPPRESSED VIRAL REPLICATION ON ANTIRETROVIRAL THERAPY

M. Hawkes[1], J. Soo[2], J. Brophy[3], F. Kakkar[4], A. Bitnun[5], L. Samson[3], S. Read[5], H. Soudeyns[6], EPIC4
*[1]University of Alberta, Pediatrics, Edmonton, Canada, [2]University of Alberta, Edmonton, Canada, [3]University of Ottawa, Ottawa, Canada, [4]Université de Montréal, Montreal, Canada, [5]University of Toronto, Toronto, Canada, [6]CHU Sainte-Justine, Montreal, Canada*
*Presenting author email: mthawkes@ualberta.ca*

**Background:** Chronic inflammation, which may predispose to cardiovascular disease (CVD), persists in HIV-1 infected adults despite sustained viral suppression (SVS). There are limited data on chronic inflammation and endothelial activation (EA) in vertically infected children. This study examines markers of inflammation and EA in virally suppressed, vertically HIV infected children enrolled in the Canadian EPIC4 cohort.
**Methods:** A cross-sectional analysis of pro-inflammatory cytokines (PIC) and measures of EA was performed in HIV-1 infected children with a viral load (VL) <40 copies/mL while on combination antiretroviral therapy (cART). Selected PIC and biomarkers of EA were measured using commercially available cytometric bead array assay (Beckton-Dickinson) and ELISA (R&D Systems).
**Results:** 43 vertically HIV-infected children were included with median age 13 years (range 3-19); 23/43 (54%) were girls. Twenty-two subjects had initiated cART in the first year of life with subsequent SVS. The remaining 21 subjects had either initiated cART after one year of age (n=6), or had at least one regimen failure before achieving SVS (n=15). PIC levels (IL-12p70, TNF, IL-10, IL-6, IL-1β, IL-8) were low (< 20pg/mL) in all but one patient. Median (inter-quartile range) levels of the biomarkers of EA markers angiopoietin-1 (Ang-1), angiopoietin-2 (Ang-2), soluble intercellular adhesion molecule-1 (sICAM-1), soluble vascular endothelial growth factor receptor-1 (sVEGFR-1), and soluble endoglin (sEng) were 16 (12-34), 0.47 (0.31-3.5), 84 (67-97), 0.53 (0.25-2.7), and 17.3 (14.4-24.0) ng/mL, respectively. Biomarkers of EA were correlated: Ang-2 with sVEGFR-1, Ang-2 with sEng, sVEGFR-1 with sEng (ρ>0.5, p< 0.01 for all comparisons). Using principal component analysis to partition the cohort into quartiles based on EA biomarkers, patients in the highest quartile with respect to EA also had higher levels of PIC: TNF (p=0.005), IL-12p70 (p=0.001), and IL-10 (p=0.008).
**Conclusions:** Despite SVS with cART, persistent systemic EA is detected in a proportion of vertically HIV-infected children and is associated with low-level chronic inflammation. Further studies are needed to determine the significance of these findings with respect to future CVD risk and beyond.

## VIRAL DETERMINANTS OF PATHOGENESIS

### TUPEA008

### IDENTIFICATION OF FUNCTIONAL HIV-1 C ENVELOPE VARIANTS CONTAINING A PHENYLALANINE RESIDUE AT POSITION 309 OF THE HYPERVARIABLE REGION 3 IN MATCHED PERIPHERAL BLOOD AND CEREBROSPINAL FLUID

K. Sojane[1], M. Roche[2], C. Chang[3], S. Lewin[3], P. Gorry[2], T. Ndung'u[1,4]
*[1]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, [2]Burnet Institute, Centre for Biomedical Research, Melbourne, Australia, [3]Monash University, Department of Infectious Diseases, Melbourne, Australia, [4]University of KwaZulu-Natal, KwaZulu-Natal Research Institute for Tuberculosis and HIV, Durban, South Africa*
*Presenting author email: katlego.sojane@gmail.com*

**Background:** The hypervariable 3 region loop of the HIV envelope protein (Env) is the major determinant of coreceptor-usage. Approximately 99% of sequenced HIV-1 subtype C (HIV-1C) viruses have a conserved isoleucine residue at position 309 (HXB2 numbering) of Env. Viruses with leucine at Env position 309 are rare, and have enhanced infectivity of monocyte-derive macrophages. HIV-1C with phenylalanine at Env position 309 (F309) is extremely infrequent (< 1% of all sequences in the Los Alamos National Laboratory Database) and only one such virus has been functionally characterized and shown to use CCR5 for entry. HIV-1C envelope variants with F309 have not been observed in the central nervous system or reported to use CXCR4.
**Methods:** Using bulk PCR amplification, cloning and Sanger sequencing, we identified HIV-1C Env variants with the F309 residue in peripheral blood and the cerebrospinal fluid (CSF) of one treatment-naive South African study participant diagnosed with Cryptococcal meningitis. Bioinformatic analyses confirm these variants to be HIV-1C. We produced single-round reporter viruses, pseudo-typed with patient-derived envelopes bearing the F309 residue and tested their ability to enter cells expressing CCR5 or CXCR4.
**Results:** We identified 9 (4 peripheral blood-derived and 5 CSF-derived) unique HIV-1C variants bearing the Env F309 residue. Variants with other residues at Env position 309 were not detected. An analysis of 783 CSF-derived HIV-1C envelopes from the Los Alamos National Laboratory database revealed that 99.87%, 0.13% and 0% of the sequences had an isoleucine, leucine and phenylalanine, respectively, at position 309. We successfully produced two pseudoviruses with the Env F309 residue; one of the pseudoviruses was capable of infecting NP-2 cells expressing CCR5 but not CXCR4, whereas the other infected NP-2 cells expressing either CCR5 or CXCR4.
**Conclusions:** We confirm the presence of Env variants bearing the F309 residue in the CSF and peripheral blood of a study participant, and show variants with this residue are capable of using the CCR5 or CXCR4 coreceptor for cell-entry. Our results improve on the understanding of HIV-1C entry into target cells. Further studies are underway to understand other functions of these variants.

### THE IMPACT OF CONFOUNDING FACTORS ON DETERMINATION OF BIOMARKERS FOR NEUROCOGNITIVE DISORDERS IN HIV-INFECTED SUBJECTS

A.C. Oliveira[1], A. Penalva[2], J. Bermudez[2], M.R. Gascón[2], J. Smid[2], G. Olival[2], J. Casseb[3], C. Romano[1]
*[1]Institute of Tropical Medicine, Virology, Sao Paulo, Brazil, [2]Neuroscience Group of Institute of Infectious Diseases Emilio Ribas, Sao Paulo, Brazil, [3]Institute of Tropical Medicine, Dermatology / Allergy, Sao Paulo, Brazil*
*Presenting author email: anacarolina.soares@usp.br*

**Background:** Despite the introduction of HAART, mild forms of HIV-Associated Neurocognitive Disorders (HAND) remain highly prevalent in people living with HIV. Many potential biomarkers have been studied, but none of them proved to be useful in clinical practice so far. The aim of this study was to looking for neurodegenerative and inflammatory biomarkers in CSF of HIV-infected patients to determine a HAND biomarkers profile. We also analyzed the impact of medication, age, time of infection and other clinical and epidemiological factors on the measurement of biomarkers studied.
**Methods:** 70 HIV+ and 7 HIV- subjects were submitted to a neuropsychological assessment and classified using the Frascati criteria in: ANI, MND, HAD, HIV+ and HIV-controls groups (HIVc). Levels of neurodegenerative markers Tau, p-Tau, Aβ40, Aβ42 and inflammatory marker sCD14 were measured in CSF samples of the subjects. Age, nadir CD4+, CD4+ and CD8+, time of infection, viral load and Efavirenz use were also evaluated regarding to the biomarkers profile.
**Results:** Statistically different levels of Aβ40 between the HIV+c and HIV-c and between HIV+c and HAND groups were founded. p-Tau levels were different between HIV+c and MND, but not within HAND groups. sCD14 levels were significantly different between HIV-c and HIV+c and also between HIV+c and HAND groups. Among patients with HAND, it was possible to distinguish HAD from the milder forms. In comparison with clinical and demographic data, sCD14 showed a linear correlation with age and time of infection. Also, the average age of the groups with more severe disorders was higher.
**Conclusions:** sCD14 was very useful to discriminate HAND from no HAND groups, as well as in the differential diagnostic between HAD and milder forms of HAND. Nevertheless, the linear correlation of sCD14 with age and time of infection make it not valuable in clinical practice alone since older individuals are more likely to develop HAND. On the other hand, Aβ40 showed no correlation with clinical/demographic data and also presented statistically difference between individuals with and without HAND. Despite limitations, results so far suggest that Aβ40 and sCD14 together can be helpful on the diagnosis of HAND.

## TUPEA010

### ASSOCIATION BETWEEN DUAL TIM-3 AND PD-1 EXPRESSING CD4 T CELLS AND NEUROCOGNITIVE FUNCTION IN CHRONIC STABLE HIV DISEASE

B.I. Mitchell[1], G.M. Chew[1], M.M. Byron[1], R.H. Paul[2], K.J. Kallianpur[1], B.K. Nakamoto[1], D.C. Chow[1], C.M. Shikuma[1], L.C. Ndhlovu[1]
*[1]University of Hawaii, Hawaii Center for AIDS, Honolulu, United States, [2]University of Missouri-St. Louis, The Missouri Institute of Mental Health, St. Louis, United States*
*Presenting author email: brooksim@hawaii.edu*

**Background:** HIV-associated neurocognitive disorders (HAND) is hypothesized to be a result of neuro-inflammation in the CNS; however the role of T-cells subsets remains ill-defined.
**Methods:** We utilized multi-parametric flow-cytometry to investigate markers of T-cell activation (CD38+HLA-DR+), senescence (CD57+CD28-), and exhaustion (TIM-3, PD-1 and TIGIT inhibitory receptors) in cryopreserved peripheral blood mononuclear cells in 33 HIV-infected individuals on stable cART with available age- and education-adjusted neuropsychological tests sensitive to HIV, including tests of psychomotor speed, working memory, executive function, and memory. Spearman correlations were conducted to examine relationships between T-cell phenotypes, global or sub-domain-specific standardized z-scores as measure of NP performance (NPZ) and to previously obtained monocyte counts for classical (CD14+CD16-), intermediate (CD14+CD16+) and non-classical (CD14+/lowCD16++) subpopulations.
**Results:** Participants were mostly male (84%) with a median age 52 years, and median current CD4 T-cell count of 479 cells/mm$^3$. Detectable viral load (>50 copies/ml) was noted in 12% of the participants. Results revealed a significant relationship between higher TIM-3+ CD4 T cell frequencies and executive function (rho=-0.371, *p*=0.034) and a trend for working memory NPZ (rho=-0.292, *p*=0.099). Additionally, double positive PD-1+TIM-3+ CD4 T cells correlated significantly with executive function (rho=-0.476, *p*=0.005), working memory (rho=-0.407, *p*=0.019), global NPZ (rho=-0.318, *p*=0.093). Higher percentages of PD-1+TIM-3+ CD4 T-cells were associated with lower immune function as measured by CD4 T-cell counts (rho=-0.545, *p*=0.001). PD-1+TIM-3+ CD4 T-cells correlated with both senescent (CD4+ CD57+CD28-;rho=0.462, *p*=0.008 and CD8+CD57+CD28-;rho=0.458, *p*=0.008) and with CD8 T-cell activation (CD8+HLA-DR+;rho=0.578, *p*=0.002). Moreover, higher PD-1+TIM-3+ CD4 T-cell frequencies were associated with higher counts of CD16+ monocyte subpopulations [intermediate (CD14+CD16+);rho=0.454, *p*=0.020 and non-classical (CD14+/lowCD16++); rho=0.534, *p*=0.005]. Even with the exclusion of individuals with detectable viremia, all these findings remained significant. No associations with NPZ were observed for TIGIT or senescent markers on CD4 T-cells or with any of these surface markers on CD8 T-cells.
**Conclusions:** Dual expression of immune exhaustion markers, PD-1 and TIM-3, on CD4 T-cells is associated with lower neurocognitive performance. CD4 T-cell exhaustion and increase CD16+ monocytes may be interrelated processes involved in HAND. Novel immunotherapy targeting PD-1 and TIM-3 may be considered as treatment modalities for HAND.

## HIV-1 CONTROLLERS (INCLUDING POST-TREATMENT CONTROLLERS)

## TUPEA011

### POST-TREATMENT CONTROL OR TREATED CONTROLLERS? THE IMPACT OF ART ON TIME TO VIRAL REBOUND IN RECENT SEROCONVERTERS

G.E. Martin[1], M. Gossez[1], J.P. Williams[1], W. Stöhr[2], J. Meyerowitz[1], E.M. Leitman[3], G. Ramjee[4], K. Porter[2], S. Fidler[5], J. Frater[1,6,7], SPARTAC Trial Investigators
*[1]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, [2]University College London, Medical Research Council, Clinical Trails Unit, London, United Kingdom, [3]University of Oxford, Department of Paediatrics, Oxford, United Kingdom, [4]Medical Research Council HIV Prevention Research Unit, Durban, South Africa, [5]Imperial College London, Division of Medicine, Wright Fleming Institute, London, United Kingdom, [6]Institute for Emerging Infections, Oxford Martin School, Oxford, United Kingdom, [7]Oxford National Institute of Health Research Biomedical Research Centre, Oxford, United Kingdom*
*Presenting author email: genevieve.martin@ndm.ox.ac.uk*

**Background:** In certain individuals who commence antiretroviral therapy (ART) in primary HIV infection (PHI) stopping treatment is not followed by viral rebound, but rather a period of aviraemia or 'viral remission'. However transient viraemic control may also occur in untreated PHI before the plasma viral load (VL) becomes detectable. Characterising these untreated patients is critical to understanding the additional impact of ART on 'time to rebound' in treatment interruption (TI) studies. We studied patients randomised to initiate immediate or deferred ART at the time of PHI to compare factors impacting time to viraemia.
**Methods:** Participants with PHI in the SPARTAC RCT were randomised to 0, 12 or 48 weeks of ART. We defined 'control' as plasma VL< 400 copies/mL for at least 16 weeks after randomisation if untreated, or from TI if ART was initiated. For treated and untreated controllers we compared Total HIV-1 DNA, HLA Class I alleles, HIV-1-specific CD8 T cell responses, and markers of T cell activation (CD25, CD38, CD69, HLA-DR) and exhaustion (PD-1, Tim-3, Lag-3).
**Results:** 35 of 361 (9.7%) trial participants fulfilled the definition of control; 10/128 (7.8%) were untreated, 9/114 (7.9%) received ≤12 weeks ART (mean 11.9 weeks) and 16/119 (13.4%) >12 weeks of ART (mean 47.7 weeks). At baseline, controllers, both treated and untreated, had lower HIV-1 DNA levels (p< 0.001), lower VLs (p< 0.001) and higher CD4 counts (p=0.002) than non-controllers.
When comparing untreated and treated controllers, those who had received >12 weeks ART had significantly higher pre-therapy VL than untreated controllers (3.8 vs 2.3 log copies/ml; p=0.003). However, there were no differences with respect to demography, viral subtype, HLA allele frequency, baseline HIV-1-specific T cell immunity (median [range]: 1 [0,9], 1 [0,4] Gag OLP responses for >12 and 0 weeks ART, respectively), CD4 count, HIV-1 DNA, immune exhaustion or activation marker expression. Importantly, the duration of viral control did not vary between treatment groups (p=0.218).
**Conclusions:** These data shows that some untreated patients during PHI experience prolonged viral control, and suggest that the impact of early ART on post-treatment control may be overestimated if the dynamics of viral rebound in untreated individuals are not considered.

## TUPEA012

### IDENTIFICATION OF DIFFERENT HIV-CONTROLLER PHENOTYPES: LOOKING FOR THE RIGHT MODEL OF FUNCTIONAL CURE

B. Dominguez-Molina[1], L. Tarancon-Diez[1], S. Hua[2], C. Abad-Molina[3], E. Rodriguez[4], F. Vidal[4], X.G. Yung[2], M. Leal[1], M. Lichterfeld[2], E. Ruiz-Mateos[1]

*Presenting author email: beadominguezmolina@gmail.com*

**Background:** HIV-controllers are a rare group of patients that maintain HIV viremia at low levels without antiretroviral treatment. However, some HIV-controllers differ in terms of clinical outcomes, CD4 T-cell counts and immune activation. Our aim was to find unbiased and premature markers that enable to discern HIV-controller phenotypes regarding clinical progression (CD4+ T-cell drop).
**Methods:** We have analysed the prevalence of IFNL4 ss469415590 polymorphism and HLA-B haplotypes among 100 HIV-controllers (< 2000 HIV-RNA copies/ml in absence of antiretroviral treatment for at least 1 year) Long Term Non-Progressors (CD4+T cells counts>500 for more than 7 years since HIV-infection) (LTNP-C) and 40 HIV-controllers non Long Term Non-Progressors (nonLTNP-C) coming from the Spanish AIDS Research Network HIV-Controllers Cohort (ECRIS). We validated these results in 914 white HIV-controllers (52.8% LTNP-C) included in a genome wide association study (GWAS) from the International HIV-controller Study. The IFNL4 polymorphism included in the GWAS was rs12980275 which is in strong linkage disequilibrium with ss469415590 ($r^2$=0.901). In a subgroup of patients HIV-specific T-cell response and soluble cytokines array were analysed.
**Results:** After adjusting for sex, age at HIV-diagnosis, favorable IFNL4 genotype, HLA-B27, HLA-B57, HLA-B35 and HLA-B08 haplotypes, the factors independently associated with LTNP-C in both cohorts were favorable IFNL4 genotype (as a risk factor, OR=0.401 (0.171-0.942) *p*=0.036 and OR=0.643 (0.439-0.944) *p*=0.024, respectively) and HLAB-57 (as a protective factor, OR=3.056 (1.029-9.069) *p*=0.044 and; OR=1.909 (1.243-2.931) *p*=0.003, respectively). In the ECRIS cohort it was also associated with sex, while in the International HIV-controller Study there was an association with age at HIV diagnosis. LTNP-C showed lower plasma IP-10, IL-8 and TRAIL levels (*p*= 0.019, 0.053 and 0.039, respectively) and higher IL1RA, IFNγ and IL13 (*p*= 0.02, 0.016 and 0.05, respectively). Moreover, LTNP-C exhibited higher IL2+CD8+CD57- and IFNγ+CD8+CD57- HIV-specific T-cells (*p*=0.002 and 0.041, respectively) than nonLTNP-C.
**Conclusions:** We have unveiled genetic markers able to segregate HIV-controllers into LTNP-C and nonLTNP-C. This finding makes possible to identify those controllers at risk of a CD4 T cell drop and opens the door to potential therapeutical interventions. These results encourage reconsidering LTNP-C as a right model of HIV functional cure.

## TUPEA013

### HIV VIROLOGICAL CONTROLLERS IN AN AFRICAN COHORT

Y. Moosa[1], N. Garrett[1], C. Gray[2], V. Naranbhai[3,4], C. Williamson[5], S. Abdool-Karim[3,6]
[1]*CAPRISA, HIV Vaccine and Pathogenesis, Durban, South Africa,* [2]*University of Cape Town, Immunology, Cape Town, South Africa,* [3]*CAPRISA, Durban, South Africa,* [4]*University of Oxford, Oxford, United Kingdom,* [5]*University of Cape Town, Virology, Cape Town, South Africa,* [6]*Columbia University, New York City, United States*
*Presenting author email: yumna.moosa@caprisa.org*

**Background:** The existence of HIV virological controllers shows that it is possible for the human immune system to robustly control HIV. It is hoped that a better understanding of the mechanisms of control will assist efforts to develop a functional cure. This report describes HIV controllers in an African cohort, examining their features in relation to those of their better-described counterparts in the United States and Europe.

**Methods:** Virological controllers were identified from a prospective seroincidence cohort of young women aged 21-33 years in KwaZulu Natal, South Africa (n = 245), and classified as either viraemic or elite controllers (ECs) according to their plasma viral load levels in the absence of antiretroviral therapy (ART). The clinical features, $CD4^+$ T cell and viral load trends of the elite controllers were examined in more detail, and their genetic features, including HLA and KIR haplotypes, were sequenced and analysed in relation to existing published data.

**Results:** In the cohort there were 12 viraemic (5%) and 2 elite controllers (1%). The first EC presented post-seroconversion with multiple recurrent infections of the skin, genitourinary tract and tonsils, suggestive of some degree of immune dysfunction. The second displayed no features of HIV-associated morbidity. Both ECs showed an initial viral load spike (33 500 and 741 copies/mL respectively) but shortly thereafter achieved and maintained undetectable plasma viral loads and stable $CD4^+$ counts (>500 cells/mm$^3$, average 900 cells/mm$^3$) for more than 6 years without ART. Both ECs were found to have HLA haplotypes well-described as being associated with slow progression, most notably HLA-B81* and HLA-B57* respectively. Furthermore, the first EC was found to have a KIR2DL2 subtype, also associated with slow progression.

**Conclusions:** While the overall subtype-C infected African cohort differed substantially from subtype-B infected cohorts in other parts of the world, the features of the African elite controllers correspond with those of their international counterparts, in terms of epidemiology, host genetics and associated immunological features. This suggests that progress in HIV controller science may be directly applicable in certain underresearched populations.

## HOST CELLULAR FACTORS AND LATENCY

## TUPEA014

### IDENTIFICATION OF A NEW HOST CELL HDAC COMPLEX THAT CONTROLS HIV LATENCY THROUGH DIRECT BINDING TO THE CORE PROMOTER

E. Wilhelm[1], M. Bédard[2], P. Lavigne[2], C. Hunter[3], B. Bell[1]
[1]*Université de Sherbrooke, Microbiologie et Infectiologie, Sherbrooke, Canada,* [2]*Université de Sherbrooke, Biochimie, Sherbrooke, Canada,* [3]*AB Sciex, San Francisco, United States*
*Presenting author email: emmanuelle.wilhelm@usherbrooke.ca*

**Background:** Strategies to achieve a cure for HIV/AIDS will require the therapeutic control of HIV latency whether they involve "shock and kill" activation or "deep latency" repression of HIV transcription. We have previously reported that the HIV core promoter is selectively recognized by cellular pre-initiation complexes of HIV (PICH) via its TATA box and adjacent sequences of HIV essential for Tat *trans*-activation (TASHET) element. To uncover molecular targets to therapeutically control latency we have now identified protein components of PICH and characterized their impact on HIV transcription.

**Methods:** DNA affinity chromatography coupled to mass spectrometry analysis was used to identify host cell PICH proteins that recognize TASHET. Co-immunoprecipitation was used to determine interacting partners of identified PICH proteins. Biophysical techniques including fluorescence anisotropy and circular dichroism (CD) were used to demonstrate direct PICH-DNA interactions. Chromatin immunoprecipitation (ChIP) assays were used to test PICH interactions with the HIV promoter *in cellulo*. siRNA were employed to test the impact of PICH proteins on HIV transcription *in cellulo*. HIV reporter viruses were used to test the requirement of PICH-binding sequences of TASHET for reactivation by latency-reversing agents (LRA) in infected T cells.

**Results:** We identified two new proteins in nuclear extracts from uninfected PBMC, HeLa cells, and Jurkat T cells that specifically bind to the HIV core promoter *in vitro*. These proteins, termed PICH-130 and PICH-37, interact tightly in cells as demonstrated by co-immunoprecipitation. PICH-130 and PICH-37 form part of a HDAC complex of previously unknown function that contains HDAC1 and HDAC2. Strikingly, PICH-37 directly and selectively binds the TATA and adjacent CTGC motifs within TASHET *in vitro*. PICH-37 binds the HIV promoter in infected HeLa and Jurkat cells. siRNA-mediated knock-down of PICH-130 and PICH-37 strongly reduced both Tat-activated and basal HIV transcription *in cellulo*. Intriguingly, mutation of the PICH-37-binding CTGC motifs in reporter virus completely blocked reactivation of HIV by pharmacological LRA that act via the Tat/TAR/7SK axis in T cells, but only partially reduced reactivation by HDAC inhibitors.

**Conclusions:** PICH-37 and PICH-130 form part of a novel HDAC complex that controls HIV latency and is essential for reactivation via the Tat/TAR/7SK pathway.

## HOST GENETICS OF HIV SUSCEPTIBILITY AND DISEASE PROGRESSION

## TUPEA015

### THE INFLUENCE OF HLA-TYPES ON DISEASE PROGRESSION AMONG HIV-2 INFECTED PATIENTS IN GUINEA-BISSAU

D. Thomsen[1,2], C. Erikstrup[2], S. Jespersen[1,3], C. Medina[4], D. da Silva Té[4], F.G. Correira[5], M. Christiansen[2], A.L. Laursen[3], C. Wejse[1,3,6], H. Krarup[7], B.K. Møller[2], B.L. Hønge[1,2,3], The Bissau HIV Cohort Study Group

*Presenting author email: ditte_thomsen1990@hotmail.com*

**Background:** HIV-2 is endemic to West Africa and is characterized by lower transmissibility due to lower viral load and HIV-2 infected persons usually have a slower progression to AIDS. The mechanisms behind the slower disease progression are unknown, but host genetics play an important part for progression during HIV-1 infection. Thus, several studies have found a relationship between HLA profile and time to onset of AIDS in HIV-1 infected persons while research in the relationship between HLA profile and HIV-2 disease progression is scarce.

The aim of this study was to identify specific HLA-types that influence disease progression of HIV-2 infection.

**Methods:** High resolution HLA Class I and II typing of the HLA-A, HLA-B, HLA-C, HLA-DRB1, HLA-DPB1 and HLA-DQB1 loci was performed on DNA from 54 antiretroviral treatment naïve HIV-2 infected patients from the Bissau HIV Cohort, Guinea-Bissau. HIV typing was confirmed using INNO-LIA HIV-1/2 Score. The effect of HLA type on HIV-2 RNA and CD4 cell count was assessed by multivariable linear regression analysis adjusted for sex and age.

**Results:** The included patients were a mix of seven of the most populous ethnic groups in Bissau, among these mainly Fula and Balanta. Twelve men (22%) and 42 women (78%) were included, mean age was 45 years (range 22-70) and median CD4 cell count was 361 cells/µL (IQR 167-633).

The HLA alleles DPB1*02:01 and DRB1*04:05 were associated with higher CD4 cell count at HIV diagnosis (mean difference, carriers - non-carriers: 210 cells/µL, 95%CI [37, 385] and 297 cells/µL, 95%CI [73, 521], respectively), indicating that these alleles have a protective role against HIV-2 disease progression.

DRB1*11:01 was associated with higher HIV-2 RNA level (mean difference, carriers - non-carriers: 0.75 log10 HIV-2 RNA copies, 95%CI [0.014, 1.482]), suggesting that this allele may be positively correlated with HIV-2 disease progression.

**Conclusions:** In preliminary analysis, HLA-DPB1*02:01 and HLA-DRB1*04:05 possibly protect against HIV-2 disease progression, while HLA-DRB1*11:01 may cause a faster disease progression of HIV-2. An additional 450 samples from HIV-2 infected individuals in Bissau have been collected and will be HLA typed.

## TUPEA016

### MANNOSE BINDING LECTIN GENETIC POLYMORPHISM: ABSENCE OF AN ASSOCIATION WITH HIV-1 VERTICAL TRANSMISSION IN A PMTCT CROSS-SECTIONAL SURVEY IN ZIMBABWE

R.B.L. Zinyama-Gutsire[1], M. Christiansen[2], C. Hagen[2], S. Rusakaniko[3], P.L. Hedley[2], B. Stray-Pedersen[4], R. Buzdugan[5], F. Cowan[6], C. Chasela[7]
*[1]University of the Witwatersrand, Faculty of Health Sciences, Johannesburg, South Africa, [2]Statens Serum Institut, Department of Congenital Disorders, Copenhagen, Denmark, [3]University of Zimbabwe, College of Health Sciences, Department of Community Medicine, Harare, Zimbabwe, [4]University Hospital and University of Oslo, Division of Women and Children, Rigshospitalet, Oslo, Norway, [5]University of California, Berkeley, United States, [6]CESHAAR Research Centre, Harare, Zimbabwe, [7]Human Sciences Research Council, Epidemiology and Strategic Information Unit, Pretoria, South Africa*
*Presenting author email: gutsirerbl@yahoo.com*

**Background:** Mannose Binding Lectin (MBL) is a normal liver-derived protein, which is a key component of the innate immune system. In the absence of serum/plasma measurements, *MBL2* genotypes can be used as proxy. MBL deficiency leads to defective opsonisation activities of the innate immune system and increased susceptibility to several infections including HIV-1. The main objective of this study was to determine prevalence of MBL deficiency, as estimated by *MBL2* haplotypes among Zimbabwean mothers and their children aged 9-18 months old as well as its association with risk of HIV-1 infection and vertical transmission from their HIV positive mothers.
**Methods:** We assessed *MBL2* polymorphisms in Zimbabwean HIV positive mothers and their children enrolled in a national PMTCT survey carried out in 2012. MBL deficiency was defined as presence of *A/O* and *O/O* genotypes in the mothers and their children. We extracted DNA from two dried blood spots for 622 mothers and infant pairs using the Gene Extract and Amp kit reagents. *MBL2* Exon 1 genotypes and promoter region alleles *-221(X/Y)* and *-550(H/L)* SNP were detected by pyrosequencing. Differences in distribution frequency between HIV infected and uninfected children, of the *MBL2* genotypes, promoter region variants and *MBL2* haplotypes, were determined by Chi square test or Fisher's exact tests.
**Results:** The median age (IQR) of the mothers was 30 (26 - 34) years and the children mean age (IQR) was 12 (11-15) months old at the time of enrolment. All 622 mothers were HIV-1 infected, 574 babies were HIV negative and 48 were HIV-1 positive babies. *MBL2* normal structural allele *A* and variants *B (codon 5A>G)*, *C (codon 57 A>G)* and promoter region SNPs *-550(H/L)* and *-221(X/Y)* were detected. Prevalence of MBL deficiency was 34% among the mothers and 32% among the children. We found no association between maternal *MBL2* deficiency and HIV-1 transmission to their children. We found no difference in the distribution of HIV-1 infected and uninfected children between the *MBL2* genotypes of the mothers and those of the children.
**Conclusions:** MBL deficiency was not associated with HIV-1 infection among the children nor was it associated with HIV-1 vertical transmission in this study population.

## MUCOSAL TRANSMISSION

## TUPEA017

### SERUM ESTRADIOL LEVEL AND SUBJECT AGE ARE ASSOCIATED WITH *EX VIVO* HIV INFECTION IN HUMAN CERVICAL TISSUE

G. Villegas[1], G. Calenda[1], M. Cooney[1], A. Reis[2], L. Posner[2], L. Mamkina[1], N. Kumar[1], T. Kalir[2], R. Sperling[2], N. Teleshova[1]
*[1]Population Council, New York, United States, [2]Icahn School of Medicine at Mount Sinai, New York, United States*
*Presenting author email: nteleshova@population.org*

**Background:** There is an ongoing debate whether sex hormone levels at the time of HIV exposure impact mucosal infection. Macaque studies demonstrated that pretreatment with estrogen protects against vaginal SIV transmission. The current study evaluated if serum and tissue estradiol (E2) and progesterone (P4) levels predict the *ex vivo* susceptibility of cervical tissue to HIV and the tissue level of HIV infection.
**Methods:** Cervical tissues and peripheral blood samples were derived from 44 subjects undergoing routine hysterectomies (31 not using hormonal contraception/treatment and 13 using hormonal contraception/treatment). Ecto- and endocervical explants (3x3mm) were challenged with 500 or 50 $TCID_{50}$ of HIV-$1_{Bal}$ vs. 3TC control for ~18h. Following washout, tissues were cultured for 14d. Infection was monitored in tissue supernatants by HIV *gag* qRT-PCR. SOFT and CUM endpoint analyses were performed. E2 and P4 concentrations were measured in serum and tissues (RIA). Log-normal generalized mixed models were used for statistical analysis.
**Results:** Higher serum E2 level was associated with lower cervical tissue susceptibility to HIV infection (decreased number of productively infected tissue replicates; p< 0.01) and lower HIV infection level (p< 0.01 for SOFT and CUM). A 100 pg/ml increase in serum E2 corresponded to a decrease in the odds of infection and level of infection by 48% and ≥49%, respectively. No E2
(LLOQ < 10 pg/ml) was detected in tissues. P4 (LLOQ < 0.2 ng/ml) was detected only in two tissue samples from subjects with serum P4 levels ≥9 ng/ml. Age was associated with tissue susceptibility to infection and infection level (p< 0.05). With each year increase in age, the odds of infection increased by 36% and infection level increased by 13-14%. Race, serum P4, serum P4/E2 ratios, endometrial histology (secretory or proliferative endometrium), and cervical histology (inflammation, metaplasia) did not predict cervical tissue susceptibility to infection or infection level. All results were adjusted for the use of hormonal contraception/treatment.
**Conclusions:** Agreeing with the protective effect of estrogen treatment against vaginal SIV transmission, our data suggest a protective role of E2 against HIV transmission in cervical mucosa. The data also suggest that increased age may increase susceptibility to mucosal HIV infection.

## TUPEA018

### HIV-1 CONSTRUCTS DO NOT TRIGGER MACROPHAGE INFLAMMATORY PROTEIN - 3 ALPHA SECRETION IN HUMAN GENITAL EPITHELIAL CELL MODELS

S. Sibeko[1], J. Makinde[2], S. Rowland-Jones[1], R. Shattock[2]
*[1]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, [2]Imperial College London, Department of Medicine, London, United Kingdom*
*Presenting author email: sengeziwe.sibeko@ndm.ox.ac.uk*

**Background:** Macrophage inflammatory protein - 3 alpha (MIP-3α), a chemoattractant for plasmacytoid dendritic cells, was shown in a landmark study to accumulate in the endocervix in the first three days post exposure to SIV-containing inoculum and prior to recruitment of SIV RNA+ CD4+ T cells in macaques. We hypothesized that MIP-3α secretion is upregulated in the endocervical sub compartment of humans following HIV exposure, when the viral envelope proteins interact with the apical epithelial surface. We assessed patterns of its secretion, changes in which could potentially alter the risk of HIV infection in women.
**Methods:** We studied patterns of constitutive secretion of MIP-3α in various female genital tract (FGT) models including cell lines; primary epithelial cells (EPEC), cervicovaginal fluid (CVF) and endocervical explant tissue (EET). We then stimulated HEC-1A cells grown on permeable supports and EET with various envelope and non envelope HIV-1 preparations including s*oluble gp140 trimeric protein*, *gp120 virus-like particles (VLPs)*, *R5 tropic whole virus, HIV-1 strain BaL,* and NL4-3 deleted in Env. We also induced with Toll like receptor ligands (TLRs) 1 through 6. We analysed MIP-3α levels in supernatants by a sandwich quantitative ELISA and Luminex immunoassays.
**Results:** We showed that MIP-3α is secreted constitutively at high levels throughout the studied FGT sites with the levels being highest in the endocervical tissue models at 941pg/mL (SD±221) and 715pg/ml (SD±84.7) in the EET and EPEC, respectively. However, levels were not further elevated after stimulation with either various HIV-1 preparations or TLR ligands in the EET. Contrary to EET, HEC-1A cells responded differentially to TLR ligands while similarly to EET they did not respond to various viral preparations - using various viral concentrations and stimulating from both poles of the membrane did not have any further impact on triggering MIP-3α levels.
**Conclusions:** Given that levels of expression of MIP-3α by human FGT epithelial models (unlike in macaques) are not influenced by HIV-1 preparations, its role in modulating initial events of HIV-1 infection remains to be defined. It is hence important to consider the extent of the mediatory role of MIP-3α in the association between HIV exposure and the outcome of infection.

## TUPEA019

### DYNAMICS OF HIV AND ITS TARGET CELLS IN THE FEMALE REPRODUCTIVE TRACK DURING ACUTE INFECTION AND AFTER THERAPY

J.V. Garcia-Martinez[1], A. Wahl[2]
*[1]University of North Carolina, Chapel Hill, Internal Medicine/Infectious Diseases, Durham, United States, [2]University of North Carolina, Chapel Hill, Internal Medicine/Infectious Diseases, Chapel Hill, United States*
*Presenting author email: awahl@med.unc.edu*

**Background:** The landmark HIV prevention trials network study 052 demonstrated that HIV transmission in discordant couples can be dramatically reduced by treating the infected individual with antiretroviral therapy (ART). However, the cellular and virological events in the female reproductive tract (FRT) during ART that results in such a decrease in transmission rates were not studied and remain unknown.

**Methods:** To asses HIV infection in the female reproductive tract and the dynamics of HIV target and effector migration/exit we used humanized BLT mice. Mice were infected with transmitted/founder viruses. Virus replication in plasma,cervicovaginal secretions and vagina was monitored using viral load analysis. For suppression of HIV replication in vivo BLT mice were treated with raltegravir, emtricitabine and tenofovir.

**Results:** Our results demonstrate that the entire FRT of BLT mice is reconstituted with human $CD4^+$ cells that are shed into cervicovaginal secretions (CVS). A high percentage of the $CD4^+$ T cells in the FRT and CVS express CCR5 and are potential HIV target cells. Infection with HIV causes an increase in the numbers of $CD4^+$ and $CD8^+$ T cells in CVS. Furthermore, during infection HIV is present in CVS. Finally, we evaluated the effect of ART on HIV levels in the FRT and CVS. Our results demonstrate that ART can efficiently suppress cell-free HIV-RNA in CVS, despite residual levels of HIV-RNA+ cells in both the FRT and CVS.

**Conclusions:** Our results demonstrating parallel reductions in the percentage of $CD4^+$ T cells in the FRT and CVS of BLT mice indicate that the cell populations are closely linked throughout the course of infection. These striking similarities between the dynamics of T cells present in CVS and the FRT after HIV infection suggest that cells from CVS could be potentially used as a reasonable surrogate reflecting some of the changes occurring in the FRT. The finding showing the absence of cell-free HIV in CVS during ART, but the continued presence of infected cells producing HIV-RNA could have potentially important implications for HIV prevention and eradication strategies. In summary, our results demonstrate that the FRT represents an important HIV reservoir during therapy.

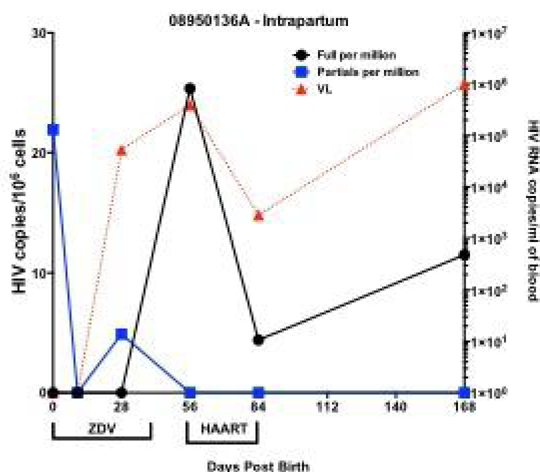
*Presenting author email: dvatakis@ucla.edu*

**Background:** Little is known about the early dynamics of HIV cDNA species in recently exposed, and infected infants while receiving ARV prophylaxis.

**Methods:** In a sub set of high-risk, non-breast fed infants enrolled in a perinatal trial comparing different antiretroviral regimens for post-exposure prophylaxis to prevent HIV mother-to-child transmission, we serially analyzed kinetics of partially and completely reverse transcribed HIV cDNA in the first 24-weeks of life (< 48hr, 2 , 4 , 8 , 12 , and 24 weeks of age) in 10 infants in whom timing of infection was known (*in-utero* or intrapartum based on presence of HIV DNA /RNA by PCR at birth). HIV-1 cDNA species were quantified using digital droplet PCR in genomic DNA isolated from peripheral blood mononuclear cells.



[Figure 1]

**Results:** We studied 10 HIV infected infants (3 in-utero, 7 intrapartum). Overall, the results show that proviral HIV cDNA levels generally correlate with HIV RNA levels in response to ARV (range 0.5-20 cp per million cells). Preliminary data of HIV kinetics suggests that early detection of incomplete reverse transcripts prior to detection of HIV cDNA or RNA in some intrapartum neonatal HIV infections and their appearance in response to ARV provides new insights into early infection. For example, in Figure 1, this intrapartum infected infant tested negative for HIV DNA but had detectable incomplete reverse transcripts. While ZDV treatment partially blocked reverse transcription, it was not sufficient as reverse transcripts reappeared leading to productive infection.

**Conclusions:** Immediate cART as prophylaxis markedly decreases the quantity of proviral reservoirs and alters early viral kinetics in infected neonatal cells. However, the rapid rescue of reverse transcription, an event not common in adult naïve T cells, suggests HIV replication in neonates is more efficient. Consequently, detection of early reverse transcripts in addition to proviral DNA provides new insights into the dynamics of very early infection.

# ACUTE AND EARLY INFECTION

*Presenting author email: wannal@cdc.gov*

**Background:** Detection of acute HIV-1 infection (AHI) is critical for early HIV treatment and prevention. We identified AHI in men who have sex with men (MSM), and in transgender women (TGW), attending the Silom Community Clinic (SCC) for voluntary counseling and testing (VCT) services in Bangkok, Thailand and assessed associated risk factors.

**Methods:** The SCC offers voluntary HIV-1 counseling and rapid serologic testing for MSM and TGW. We used an HIV-1 rapid test (Determine) to screen for HIV. Positive results were confirmed by two additional rapid tests (DoubleCheck, SD Bioline). Persons with negative rapid tests were screened for AHI using a pooled HIV-1 nucleic acid amplification test (NAAT, Aptima). AHI in those with a NAAT-positive result was confirmed by viral load (Roche) or fourth-generation enzyme immunoassay (EIA, Abbott). AHI was defined as being anti-HIV-1 antibody negative with the presence of HIV-1 RNA or p24 antigen. We describe behavioral and laboratory factors for persons with AHI.

**Results:** From June 2009 to November 2015, 9,167 persons made 21,773 visits to VCT services. Overall, 8,747/9,167 (95%) assented to HIV testing; the prevalence of HIV-1 infection by rapid tests was 32.8% (95% CI 31.9-33.8). Among 5,874 persons with negative rapid tests, we performed NAAT testing in 5,806 (98.8%), and detected AHI in 68 (1.1%, 95% CI 0.9-1.4). Persons with AHI had a median age of 27 years (IQR 23-32), and 62% were aged 17-29 years. Characteristics of persons with AHI included recent unprotected anal sex (n=63, 93%), history of a sexually transmitted disease (n=28, 41%), hepatitis immunity (hepatitis B surface antibody, n=27, 40%, hepatitis A, n=16, 24%), and any AHI symptoms (n=19, 28%). However, 72% of persons with AHI did not report any AHI symptoms.

**Conclusions:** We detected AHI in 1.1% of MSM and TGW who initially tested HIV negative at SCC VCT. Incorporating screening for HIV-1 NAAT and p24 in persons reporting risk exposure or factors linked with AHI leads to detection of acute infection as resources allow, and increases the possibility of early treatment and prevention of HIV transmission.

## TUPEA022

### COMPARISON OF HIV EPITOPES AVAILABILITY BETWEEN ACUTE AND CHRONIC INFECTION

G. Damilano[1], G. Turk[1], O. Sued[2], E. Socias[2], M.J. Ruiz[1], F. Guzman[3], H. Salomón[1], D. Dilernia[4]
*[1]Biomedical Research on Retroviruses and AIDS, Dpto de Microbiología, Facultad de Medicina, Universidad de Buenos Aires, Capital Federal, Argentina, [2]Fundación Hésped, Buenos Aires, Argentina, [3]Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile, [4]Emory University, Atlanta, United States*
*Presenting author email: gabrieldario06@hotmail.com*

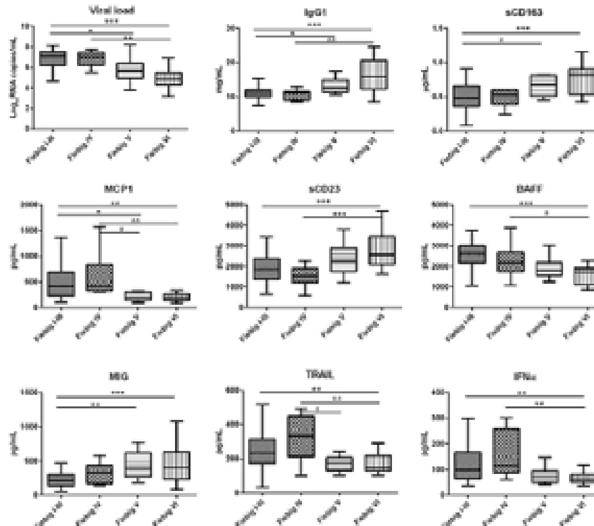
**Background:** Recent studies indicate that there is selection bias for transmission of viral polymorphisms associated with higher viral fitness. Furthermore, after transmission and before a specific immune response is mounted in the recipient, the virus undergoes a number of reversions which allow an increase in their replicative capacity. These aspects, and others, affect the viral population characteristic of early acute infection.
**Methods:** 70single *Gag*-gene amplifications were obtained by limiting-dilution RT-PCR from plasma samples of 5 ARV-naïve patients with early acute infection (< 60days, 29 days average) and 5 ARV-naive patients with a year of infection (7amplicons per patient). Sanger sequencing and NGS SMRT technology (Pacific Biosciences) were implemented to sequence the amplicons. HLA-I typing was performed by SSOP-PCR method. The chromatograms were analyzed with Sequencher 4.10. Epitopes prediction was performed with NetMHC CBS prediction server for the 19 HLA-A and -B alleles most prevalent in our population with peptide lengths from 8 to 14 Aa. Citotoxic response prediction was performed by using the IEDB Analysis Resource.
**Results:** After implementing epitope prediction analysis, we identified a total number of 110 viral epitopes present in two or more acute or chronic patients. 63.6% (n=70) of them were present only in acute infection (prevalent acute epitopes) while 36.4% (n=40) were present only in chronic infection (prevalent chronic epítopes). Within p24, the difference was even more dramatic with 85.7% (18/21) being acute epitopes. This is consistent with progressive viral adaptation to immune response in time and further supported by the fact that citotoxic response prediction shows that acute epítopes are more likely to generate immune response than chronic epítopes. Interestingly, only 15.2% of acute epítopes match the population-level consensus sequence of the virus. Deep NGS indicates that there is not significant variability in epitopes sequences.
**Conclusions:** Our results indicate that certain non-consensus viral residues might be transmitted more frequently than consensus-residues when located in immulogicaly relevant positions (epítopes).This observation might be relevant to the rationale behind development of an effective vaccine.

## TUPEA023

### IDENTIFICATION OF A CYTOKINE EXPRESSION PATTERN SPECIFIC FOR THE FIRST MONTH OF HIV INFECTION

L. Pastor[1,2], E. Parker[3], J. Carrillo[2], V. Urrea[2], L. De la Fuente[1], J. Coll[2], C. Jairoce[4], L. Luis[4], I. Mandomando[4], J. Blanco[2], D. Naniche[1]
*[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]IrsiCaixa Institute for AIDS Research, Institut Germans Trias i Pujol (IGTP), Hospital Germans Trias i Pujol, Universitat Autonoma de Barcelona (UAB), Badalona, Spain, [3]School of Paediatrics and Child Health, University of Western Australia, Perth, Australia, [4]Centro de Investigaçao em Saude de Manhiça (CISM), Manhiça, Mozambique*
*Presenting author email: lucia.pastor@isglobal.org*

**Background:** Acute HIV infection (AHI) is the initial phase of infection where HIV is actively replicating but seroconversion has not yet occurred. AHI is characterized in most of the cases by a transient non-specific febrile illness. Massive inflammatory response and intestinal damage are also developed at this stage. The main objective of this study was to identify patterns of immune biomarkers which differentiate the early Fiebig stages of AHI during HIV subtype C infection.
**Methods:** A fever based screening was used to identify AHI in subjects presenting at the Manhiça District Hospital (MDH) in Southern Mozambique. AHI was defined as HIV serology rapid test negative or indeterminate and HIV RNA positive. Plasma levels of inflammation, immune response and intestinal damage biomarkers were determined by luminex or ELISA techniques. Western blots were performed to complete Fiebig staging. Identification of patterns of biomarkers by Fiebig stage was assessed by multivariate analysis using a Random Forest model.
**Results:** Of 3111 eligible individuals with a negative or indeterminate HIV rapid test result, 85 (2.7%) had positive HIV RNA viral load and were enrolled as AHI of which n=45, 8, 12 and 20 were classified as Fiebig I-III, IV, V and VI stages respectively. Median age of the AHI group was 24 years (IQR 10.0), and 58.8 % of the subjects were female. Group comparison showed Fiebig-differentiated patterns of expression of cytokines (Figure 1). Random Forest analysis revealed that sCD163, BAFF, MIG and MCP 1 distinguished between Fiebig I-IV and Fiebig V-VI with a sensitivity of 75% and a specificity of 87%.
**Conclusions:** Identification of plasma biomarker expression pattern specific for early HIV is a useful tool for understanding early HIV pathogenesis and may be used to identify those individuals whose intestinal damage and chronic immune activation could be potentially prevented by therapeutic interventions at this stage.



*[Figure 1. Expression of selected biomarkers varies by Fiebig stage. Of a total of 49 biomarkers assayed, n=8 were selected for significant differences between Fiebig groups by Kruskall-Wallis range comparison (Bonferroni adjusted p-value <0.01). Comparison of individual difference in expression level by Fiebig group was performed by Dunn's comparison test adjusted by Bonferroni for multiple comparisons as shown above. Significance is indicated as *** if p<0.001, ** if p<0.01 and * if p<0.05. Box as IQR, middle line as median, whiskers as Tukey values (1.5 IQR)]*

## PRECLINICAL PROPHYLACTIC DRUG DEVELOPMENT

## TUPEA025

### HIV PRE-EXPOSURE PROPHYLAXIS FOR WOMEN AND INFANTS PREVENTS VAGINAL AND ORAL HIV TRANSMISSION IN A PRE-CLINICAL MODEL OF HIV INFECTION

M. Kovarova[1], U. Mugasundaram[1], J.V. Garcia[1], A. Wahl[2]
*[1]University of North Carolina, Chapel Hill, Internal Medicine/Infectious Diseases, Durham, United States, [2]University of North Carolina, Chapel Hill, Internal Medicine/Infectious Diseases, Chapel Hill, United States*
*Presenting author email: awahl@med.unc.edu*

**Background:** Approximately 1.5 million HIV-positive women become pregnant annually. Without treatment, up to 45% will transmit HIV to their infants, primarily through breastfeeding. These numbers indicate the fact that HIV acquisition is a major health concern for women and children globally. They also highlight the urgent need for novel approaches to prevent HIV acquisition that are safe, effective and convenient to use by women and children in places where they are most needed.
**Methods:** The efficacy of oral EFdA PrEP to prevent vaginal and oral HIV infection *in vivo* was evaluated by exposing EFdA-treated and untreated BLT humanized mice vaginally ($HIV\text{-}1_{JR\text{-}CSF}$, $HIV\text{-}1_{CH040}$ and $HIV\text{-}1_{RHPA}$) or orally ($HIV\text{-}1_{JR\text{-}CSF}$, $HIV\text{-}1_{CH4419}$ and $HIV\text{-}1_{THRO}$) to three consecutive high dose HIV challenges. EFdA was administered via oral gavage (10 mg/kg) once daily for eight days and mice were challenged with HIV 3-4 h after the second, fourth and sixth EFdA doses. A power analysis was performed to determine experimental group sizes needed to achieve ~90% power.
**Results:** Using highly relevant transmitted-founder (T/F) viruses, we evaluated the ability of a novel and potent reverse transcriptase inhibitor, EFdA, to prevent vaginal and oral HIV transmission using a pre-clinical model of HIV infection. Our results show strong HIV inhibitory activity in serum, cervicovaginal secretions and saliva obtained from animals after a single oral dose of EFdA demonstrating efficient drug penetrance into highly relevant mucosal sites. Importantly, a single daily oral dose of EFdA resulted in efficient prevention of vaginal and oral HIV transmission after multiple high-dose exposures to T/F viruses, offering in vivo pre-clinical data supporting the use of EFdA as a pre-exposure prophylaxis (PrEP) agent to prevent HIV infection in both women and infants.
**Conclusions:** Significant gender inequalities limit the ability of women to access and exercise HIV prevention options resulting in earlier acquisition of infection, higher transmission rates and increased mother-to-child transmission of HIV. Our results demonstrating excellent efficacy in preventing both vaginal and oral HIV transmission together with EFdA's relatively low toxicity and high potency against drug-resistant HIV strains support its use in both women and infants, the two of the most vulnerable populations at risk for acquiring HIV.

## MYCOBACTERIA AND TUBERCULOSIS

### TUPEA026

### EVALUATION OF THE LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) ASSAY FOR THE DETECTION OF M. TUBERCULOSIS (TB) IN SYMPTOMATIC TUBERCULOSIS PATIENTS ATTENDING A PRIMARY HEALTHCARE CLINIC (PHC) IN DURBAN

S. Reddy
*Medical Research Council, HIV Prevention Research Unit, Durban, South Africa*
*Presenting author email: shabashini.reddy@gmail.com*

**Background:** Tuberculosis remains a major global health problem. Delays in diagnosis and treatment initiation result in prolonged transmission and increased infectiousness of the patients.
KwaZulu-Natal is the epicenter of the HIV epidemic with approximately 70% of people co-infected with HIV and TB. Undiagnosed TB is a major contributor to the high mortality in HIV infected patients. We evaluated and compared the diagnostic accuracy of the TB LAMP assay, smear microscopy and GeneXpert to the gold standard of TB culture in TB suspects.
**Methods:** Two sputum specimens (one for routine GeneXpert test and the second for TB LAMP, smear microscopy and TB culture) were collected after obtaining informed consent from eligible TB suspects attending a Primary Health Care Clinic. DNA was extracted from raw sputum and amplified according to the manufactures instructions (Eiken Chemical Company, Japan) using the Loopamp™ Extraction and Detection Kits. The remaining sputum were examined using florescent microscopy (Auramine O staining) and cultured into the BACTEC MGIT 960 system. Culture positive samples were confirmed with Ziehl-Neelson staining and a Line-probe assay.
**Results:** A total of 695 samples were collected for the TB LAMP test. The TB LAMP test has a slightly lower sensitivity (72.6% vs 76.0% p = 0.4487) and significantly higher specificity (96.8% vs 92.9%, p = 0.0242) than the GeneXpert assay when compared to all Culture Positive samples, respectively. In Smear-positive-Culture-positive samples, the sensitivity of TB LAMP versus culture compared to GeneXpert versus culture was 95.9% and 97.6% respectively. Within Smear-negative-Culture-positive samples, the sensitivity of the TB LAMP was lower (55.9%) than that of GeneXpert (66.1% p = 0.2654). The lower sensitivity could be due to the shorter assay time to diagnosis (1 vs 2 hours) and less sample input volume (60μl vs 1000μl).
**Conclusions:** The TB LAMP test has ease of operability and the findings of this study suggest similar sensitivity to the GeneXpert. This test has the potential to be implemented as a point-of-care test in the Primary Health Care setting and can contribute to reduction in primary defaulters, reduction of treatment waiting times, reduction of TB prevalence and improve health outcomes in HIV positive patients.

### TUPEA027

### HIGH-RISK HUMAN PAPILLOMAVIRUS TYPES IN HIV-INFECTED AND UNINFECTED YOUNG WOMEN IN A CROSS-SECTIONAL STUDY IN KWAZULU NATAL, SOUTH AFRICA: IMPLICATIONS FOR VACCINATION

J.N. Mbatha[1,2], M. Taylor[3], E. Kleppa[4,5], K. Lillebø[4], H. Galapaththi-Arachchige[4,6], D. Singh[7], E. Kjetland[3,4,6], M. Baay[4,8], Z. Mkhize-Kwitshana[2,9]
*[1]Durban University of Technology and University of KwaZulu Natal, Biomedical and Clinical Technology, Durban, South Africa, [2]University of KwaZulu Natal, Infection Prevention and Control, Durban, South Africa, [3]University of KwaZulu Natal, Discipline of Public Health, Nelson R Mandela School of Medicine, Durban, South Africa, [4]Oslo University, Norwegian Centre for Imported and Tropical Diseases, Department of Infectious Diseases, Oslo, Norway, [5]Oslo Univeristy, Faculty of medicine, Oslo, Norway, [6]Oslo University, Faculty of Medicine, Oslo, Norway, [7]Durban University of Technology, Department of Physics, Durban, South Africa, [8]University of Antwerp, Department of Oncology, Antwerp, Belgium, [9]Mangosuthu University of Technology, Department of Biomedical Sciences, Durban, South Africa*
*Presenting author email: nonhlanhlam@dut.ac.za*

**Background:** High-risk human papillomavirus (hr-HPV) infections and low-grade squamous intraepithelial lesions occur frequently in young women. The available vaccines cater for up to nine hr-HPV genotypes, which may not necessarily be the most predominant types in every region worldwide. The objective of this study was to describe the hr-HPV genotypes present among HIV uninfected and infected young women in rural areas of the KwaZulu-Natal province of South Africa.
**Methods:** Cervico-vaginal lavages were obtained from sexually active young women recruited from high schools in KwaZulu-Natal (n=1223). HPV detection and genotyping were done by polymerase chain reaction using GP5+/GP6+ primers and enzyme immunoassay. HIV testing was done on serum using SD Bioline 1/2/3.0 rapid test kit and confirmatory testing with a Sensa HIV 1/2/0 Tri-line test.
**Results:** Of the 1223 cervico-vaginal lavages, 301 (25%) were positive for hr-HPV. The HPV prevalence was higher in HIV infected (32.2%, 95 CI, 0.27-0.38) than in HIV uninfected women (22.5%%, 95% CI, 0.21-0.26), p=0.001. Similarly, multiple infections were more common in HIV infected (59.3%) than in HIV uninfected women (53.5%), p=NS. The nine most predominant genotypes in descending order were HPV types 16 (n=99, 22.1%), type 51 (n=58, 12.9%), type 18 (n=56, 12.5%), type 35 (n=50, 11.1%), type 33 (n=47, 10.5%), type 56 (n=42, 9.4%), type 45
(n=34, 7.6%), type 52 (n=32, 7.1%), type 59 (n=31, 6.9%). Specifically, HPV 35, 51, 56 and 59 (40.5%) were amongst the most prevalent in the schools of KwaZulu-Natal yet not covered by the nine-valent vaccine.
**Conclusions:** Four of the most predominant high-risk HPV types in this region are not covered by the new nine-valent HPV vaccine. HPV infections in young women often clear spontaneously and the lesions regress however, this study was done in young women of an HIV high-endemic area and further research must be done to determine the clinical significance.

## ANIMAL MODELS OF TRANSMISSION, DISEASE RESISTANCE AND PROGRESSION

### TUPEA028

### TRANSCRIPTOME ANALYSIS OF DIFFERENTIALLY EXPRESSED ISG SUBSETS IN ACUTE AND CHRONIC PHASE SUGGESTS INFG PARTICIPATE IN SUSTAINING PERSISTENT ISG EXPRESSION IN PATHOGENIC SIV INFECTION IN CYNOMOLGUS MACAQUES

N. Echebli, N. Tchitchek, S. Dupuy, T. Bruel, C. Pereira Bittencourt Passaes, R. Le Grand, B. Vaslin
*CEA, INSERM U 1184, Fontenay-aux-Roses, France*
*Presenting author email: bruno.vaslin@cea.fr*

**Background:** Interferons play a major role in controlling viral infections. They are key elements in innate immunity and are needed for efficient adaptive immunity. Nevertheless, they are associated with inflammation/immune suppression/chronic-immune-activation. Persistent up-regulation of IFN-regulated-genes (ISGs) is a molecular signature of chronic-immune-activation and progression in SIV-infected non-human-primates.
IFNs/IFN-receptors interactions induce ISGs by targeting specific sequences upstream promoters (GAS, ISRE) through signal transduction (phosphorylation of latent transcription factors belonging to STAT family mediated by Janus kinases). STAT dimers directly activate ISGs containing GAS-sequences. The association of STATs with interferon regulatory factor (IRF9) activates genes by interacting with ISRE-sequences.
Our aim was to better understand the respective involvement of type I and type II IFNs in ISG induction in both acute and chronic infection, and respective functional enrichments of genes regulated by GAS or ISRE or both (GAS+ISRE) in specific biological functions.
**Methods:** Six macaques were exposed to SIVmac251 intravenously and were subjected longitudinally to Agilent Rh DNA array, in different tissues (PBMCs, lymph-nodes, rectum) focusing on acute and chronic infection. In addition, virus loads and IFN expression were monitored. We analyzed differential expression of IFNs and 1,638 ISGs that were splitted into three distinct groups, GAS-, ISRE- and GAS/ISRE-regulated-ISGs.
**Results:** Increased IFNα,b-expression was detected in lymphoid tissues during acute infection but was barely detectable during the chronic stage. In contrast, IFNg production was detected during both phases. Among 297 differentially up-regulated ISGs, 72 displayed ISRE-, 113 GAS- and 112 both ISRE/GAS-sequence(s) within 5,000bp upstream promoter. The induction of ISGs was higher in acute than in chronic phase. ISRE/GAS-ISGs were more induced than ISRE and GAS genes. Some were induced in acute or chronic or both phases (MX1,ISG15,OAS1,IRF9). ISRE+GAS ISGs were over-represented in inflammation and anti-viral canonical functions than were GAS-ISGs or ISRE-ISGs.
**Conclusions:** These results suggest that, in acute phase, both type I and type II IFNs sustain ISG expression. In the chronic phase, the absence of detectable IFN I (a,b,l) induction combined with persistent IFNg and IRF9 over-expression suggests that up-regulation of ISGs may be mainly supported by type II IFN which is produced by activated NK and T cells.

## TUPEA029

### PNS INFLAMMATION DURING ACUTE SIV

J. Mankowski, L. Mangus
*Johns Hopkins University, Dept of Molecular and Comparative Pathobiology, Baltimore, United States*
*Presenting author email: jmankows@jhmi.edu*

**Background:** Peripheral neuropathy continues to be a frequent and challenging neurologic complication of HIV infection despite antiretroviral therapy. Relatively little is known about peripheral nervous system damage during early stages of HIV infection, a time when interventions aimed at preventing nerve injury could prove most beneficial.
**Methods:** We used a well-established SIV/macaque model of HIV peripheral neuropathy to examine molecular and morphologic alterations occurring within the peripheral nervous system of 6 SIV-infected macaques during acute infection 7 days post-inoculation; 8 uninfected macaques served as controls. Comparisons were performed using nonparametric approaches corrected for multiple comparisons. A combination of mRNA, protein, and immunohistochemical analyses of the lumbar dorsal root ganglia (DRG) were performed to measure alterations in cell-specific immune activation and oxidative stress responses.
**Results:** Analyses of mRNA expression by Nanostring and qRT-PCR demonstrated significant upregulation of genes involved in Type I IFN signaling and the early antiviral response in the DRG including IRF7, Mx1, CCL8, CXCL10, and CXCL11. In addition, cellular immune activation of macrophages, represented by increased CD68 mRNA ($P < 0.001$; Mann-Whitney) and glial cell activation, represented by GFAP mRNA levels ($P = 0.0047$; Mann-Whitney) also were detected. To assess induction of an oxidative stress response we measured expression of SOD2, which encodes the mitochondrial SOD isoform, and found significant upregulation of RNA and protein with SIV infection ($P < 0.001$, Mann-Whitney). SOD2 immunostaining demonstrated an increase in the intensity of SOD2 localized primarily to the satellite glial cells and interstitial macrophages.
**Conclusions:** These findings suggest that immune activation and oxidative stress responses in the dorsal root ganglia precede and contribute to early sensory nerve injury, thereby setting the stage for progressive neuronal dysfunction. A comprehensive understanding of the early pathogenic mechanisms leading to HIV-induced peripheral nervous system damage may reveal novel neuroprotective approaches for HIV patients.

## NOVEL ANIMAL/VIRUS MODELS FOR VACCINE, CURE RESEARCH, AND INHIBITOR DEVELOPMENT

## TUPEA030

### DISTRIBUTION AND LOCALIZATION OF FLUORESCENTLY TAGGED PASSIVELY TRANSFERRED ANTIBODIES: DEFINING ANTIBODY DYNAMICS AND LOCALIZATION *IN VIVO*

A. Carias[1], J. Schneider[1], M. Anderson[1], G. Cianci[1], D. Maric[1], R. Veazey[2], T. Hope[1]
[1]*Northwestern University, Cell and Molecular Biology, Chicago, United States,* [2]*Tulane National Primate Research Center, Covington, United States*
*Presenting author email: a-carias@u.northwestern.edu*

**Background:** In the world of host-HIV interactions, non-neutralizing and broadly neutralizing antibodies have been illustrated to provide protective responses against lentiviral infections. Antibody passive transfer studies in non-human primates have demonstrated protection against HIV infection; however, the mechanism of this protection at mucosal sites is unknown. Through various approaches, we have determined antibody half-life, along with where these antibodies localize and how they enter into mucosal tissues.
**Methods:** To define antibody dynamics and localization *in vivo*, rhesus macaques were intravenously administered fluorescently tagged non-specific Gamunex-C, HIV-specific VRC01, VRC01-LS (kindly provided by John Mascola) or a combination of two of aforementioned antibodies. Additional macaques were also injected with fluorescently tagged Gamunex-C and human serum albumin. Following injection, serum, vaginal wecks, sequential vaginal biopsies, and whole necropsied vaginal tissues were collected at time points ranging from 24hours to 8 weeks. For each animal, antibody levels in serum and wecks were analyzed using fluorometric spectroscopy. Tissue fluorescent levels were measured with deconvolution microscopy.
**Results:** Antibodies were detectable in sera, wecks, and tissue as early as 24 hours and up to ~4 weeks. In all samples, antibodies reached a steady state between 1-2 weeks, however Gamunex-C persisted longer in sera than VRC01 or VRC01-LS. Antibodies, both non-specific and HIV-specific, were found to first appear in the vaginal lamina propria and move into the superficial layers through epithelial cell differentiation. Likewise, human serum albumin moved through the vaginal epithelium in a similar fashion.
**Conclusions:** Here, our data illustrate how antibodies can passively enter mucosal tissues after intravenous administration and reveal endogenous pathways of antibody distribution in mucosal squamous epithelia. Within the vaginal epithelium, we observe an apparent cell-based mechanism of antibody delivery where subsets of basal epithelial cells capture circulating passively transferred antibodies, migrate towards the surface, eventually delivering these antibodies to the lumen to interact with mucosal fluids.
Additionally, we illustrate the intra-epithelial movement of human serum albumin and antibody being synchronized, suggesting we are observing the kinetics and mechanism of transudation. These data prove essential for understanding and developing novel antibody-based preventions of HIV infection.

## DISEASE BURDEN: MORBIDITY / MORTALITY / LIFE EXPECTANCY

## TUPEB031

### GETTING THERE? LIFE EXPECTANCY BY HIV STATUS AND EDUCATION IN SWITZERLAND

A. Gueler[1], M. Zwahlen[1], A. Calmy[2], H. Günthard[3], E. Bernasconi[4], H. Furrer[5], C. Fux[6], M. Battegay[7], A. Moser[1,8], M. Egger[1,9], for the Swiss HIV Cohort Study and Swiss National Cohort

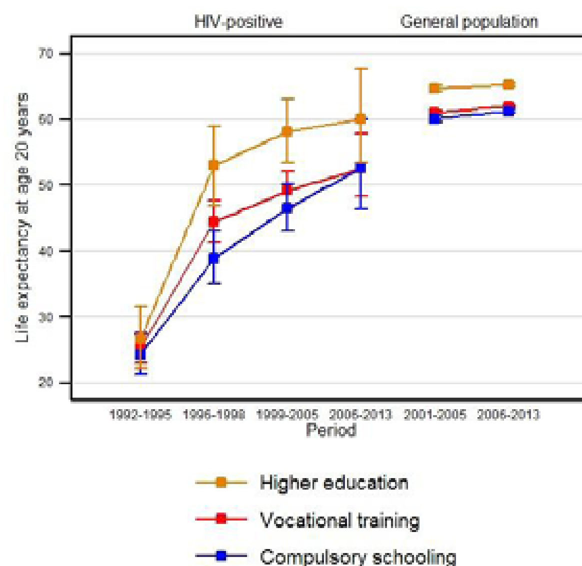
*Presenting author email: aysel.gueler@ispm.unibe.ch*

**Background:** The greater life expectancy among the highly educated compared to the less educated is well documented in many countries. We examined life expectancy by education in the Swiss HIV Cohort 1992 to 2013, and compared it with recent life expectancy by education in the general Swiss population.
**Methods:** We estimated remaining life expectancy at age 20 years using parametric survival models based on the Gompertz distribution. For each HIV-positive individual we drew a random sample of up to 100 people from the 2000 census, matched for age (year of birth), sex, and educational level (higher education, vocational training, compulsory education only). We then estimated life expectancy in the Swiss National Cohort, which links census to mortality records.



*[Figure 1. Additional life expectancy at age 20 years in the Swiss HIV Cohort and the general Swiss population by level of education]*

## RETENTION IN CARE

### TUPEB046

#### FACTORS ASSOCIATED WITH LONG-TERM ANTIRETROVIRAL THERAPY RETENTION AMONG ADOLESCENTS IN TASO UGANDA: A RETROSPECTIVE STUDY

S. Okoboi[1], L. Ssali[1], S. Kalibala[2], A. Yansaneh[3], T. Ayabo[4], F. Onyango[5]
*[1]The AIDS Support Organization, Research and Evaluation, Kampala, Uganda, [2]Population Council (HIVCore Project), Washington DC, United States, [3]US Agency for International Development, Research and Evaluation, Washington DC, United States, [4]Infectious Diseases Research Collaboration, Kampala, Tuvalu, [5]Population Council (HIVCore Project), Nairobi, Kenya*
*Presenting author email: stephenokoboi@yahoo.co.uk*

**Background:** In many sub-Saharan Africa countries, HIV programs are organized around pediatric or adult care. This has important implications for retention of adolescents in HIV care programs especially as they transition from pediatric to adult care. Retention is important for positive clinical outcomes (e.g., viral load suppression and survival). The extent to which HIV-infected adolescents have been retained in care is not well understood. We examined retention and the factors associated with non-retention among HIV-positive adolescents in Uganda's The AIDS Support Organization (TASO) clinics. TASO provides facility- and community-based antiretroviral treatment (ART) care services.
**Methods:** Using a retrospective cohort analysis, we examined clinical data of HIV-positive adolescents aged 10-19 years who initiated ART at 6 TASO clinics between January 2006 and December 2011. We defined retention as the percentage of patients known to be on treatment 12, 24, 36 and 48 months after initiation of ART. Descriptive statistics and Cox proportional hazards regression models were used to determine levels of retention and factors associated with non-retention at 24 months following ART initiation.
**Results:** A total of 617 adolescents started ART between 2006 and 2011, with an overall retention rate following ART initiation of 70% over 48 months, of which 63% were females, 55% were aged 10-14 years, 75% had primary education, and 25% were sexually active. Retention was 90% at 12 months, 83% at 24 months, 76% at 36 months, and 70% at 48 months. Retention varied by duration of treatment, with higher retention observed for patients on longer duration of treatment. Non-retention was significantly associated with clinic-based (vs. community-based) ART delivery (AHR=2.58, 95%CI: 1.26-5.29 at 12 months); CD4 >100/mm$^3$ at ART initiation (AHR=1.38, 95%CI: 1.01-1.90 at 12 months); and older adolescent age (15-19 years) (AHR=1.88, 95%CI: 1.01-3.48 at 12 months).
**Conclusions:** We observed that community-based ART delivery and early initiation on ART improved retention in treatment. There is thus a need for early diagnosis of HIV infection and community-based approaches to reach and retain HIV+ adolescents on treatment, and identification of specific groups that are at high risk of dropping out for targeted care and support.

### TUPEB047

#### IMPACT OF RELIGIOSITY ON HIV/AIDS PATIENT RETENTION IN CARE AND ART ADHERENCE IN UGANDA: A CASE STUDY OF THE INFECTIOUS DISEASES INSTITUTE, IN KAMPALA, UGANDA

A. Twimukye[1], C.B. Rwabukwali[2], J.B. Sempa[3], A. Kiragga[4], M. Nsumba[4], J. Orikiiriza[5], A. Kambugu[4], M. Lamorde[1]
*[1]Infectious Diseases Institute Makerere University College of Health Sciences, Prevention Care and Treatment, Kampala, Uganda, [2]Makerere University Faculty Of Social Sciences, Sociology, Kampala, Uganda, [3]Stellenbosch University, South African Center for Epidemiological Modeling and Analysis, Stellenbosch, South Africa, [4]Infectious Diseases Institute Makerere University College of Health Sciences, Research, Kampala, Uganda, [5]Trinity College Dublin, Paeditrics, Dublin, Ireland*
*Presenting author email: atwimukye@idi.co.ug*

**Background:** While implementation of multifaceted programs has led to substantial decline to HIV/AIDS rates, societal especially religiosity, though neglected; play an important role. Religiosity rarely attracts attention from funders and service providers, and its impact on HIV/AIDS programs is poorly understood. We aim to assess the impact of religious beliefs on the pattern of HIV service seeking behavior, at the Infectious Diseases Institute (IDI) clinic in Kampala, Uganda.
**Methods:** A cross-sectional study of 406 adult HIV patients and staff was conducted at IDI, in 2012. We used quantitative and qualitative methods of data collection. Specifically, patients were asked about their religious beliefs, divine healing and adherence to clinic appointments and antiretroviral drugs. We conducted 360 individual interviews that were stratified by religious affiliation, gender and age, and 4 focus group discussions (FGDS) for patients, and 10 key Informant interviews (KII) of selected IDI clinic staff. We used SPSS version 14 to analysis the quantitative data and thematic analysis to analyze the qualitative data.
**Results:** From 360 individual interviews, majority were Catholics 105(29.2%), then Anglicans 104 (28.9%), Pentecostals 90 (25.0%) while Muslims 48(13.3%) and Adventists 13(3.6%). Pentecostals 64(37.9%) were religiosity active and engaged in the practice of divine healing, followed by Catholics 45(26.6%), Anglicans 41(24.2%), Muslims 15 (8.9%) and Adventists 4(2.4%). Patients who engaged in divine healing reported lower rates of adherence to antiretroviral therapy (ART) and missed more clinic appointments in the prior three months (P-value < 0.001). Five themes emerged regarding religiosity including: Divine healing, Level of religiosity, benefits and risks of religiosity, and how to address religious beliefs.
**Conclusions:** There is an urgent need for HIV programs to recognize that belief in divine healing can affect ART adherence. In Uganda and similar settings, there is need to develop sensitization messages addressing religious beliefs, actively engaging religious leaders to support treatment programs. Further research is needed to elucidate the impact of religious beliefs on treatment outcomes in HIV programs.

### TUPEB048

#### RISK FACTORS FOR UNSTRUCTURED TREATMENT INTERRUPTIONS AND ASSOCIATION WITH SURVIVAL IN ART PROGRAMMES IN LOW-MIDDLE INCOME COUNTRIES

J.H. McMahon[1,2,3], T. Spelman[3], N. Ford[4,5], J. Greig[6], A. Mesic[7], E.C. Casas[7], C. Ssonko[6], D. O'Brien[6,8]
*[1]Alfred Hospital, Infectious Diseases, Melbourne, Australia, [2]Monash University, Melbourne, Australia, [3]Burnet Institute, Melbourne, Australia, [4]University of Cape Town, Cape Town, South Africa, [5]Imperial College London, London, United Kingdom, [6]Manson Unit, Medecins Sans Frontieres, London, United Kingdom, [7]Medecins Sans Frontieres, Public Health Department, Amsterdam, Netherlands, [8]Royal Melbourne Hospital, Melbourne, Australia*
*Presenting author email: ja.mcmahon@alfred.org.au*

**Background:** Treatment interruptions (TIs) to antiretroviral therapy (ART) are associated with increased risk of mortality and other adverse clinical outcomes. This study reports frequency and risk factors for unstructured TIs (uTIs) and association with survival in Médecins Sans Frontières ART programmes.
**Methods:** Programmatic data from 33 ART sites in 11 countries between 2003 and 2013 were analysed. Included variables were: gender, age, marital status, CD4 cell count and WHO stage at ART initiation. uTI was defined as a ≥ 90 day break from ART calculated from the day the previous prescription ran out until date of the next prescription. Factors predicting uTI were assessed with a conditional risk-set multiple failure time-to-event model. uTI predicting mortality was assessed using a Cox proportional hazards regression with a competing risks extension for lost to follow-up (LTFU).
**Results:** Of 40632 patients, 3386 (8.3%) died, 3453 (8.5%) were LTFU and median duration of follow-up was 1.61 years (IQR: 0.54-3.31). There were 14817 uTIs of ≥ 90 days with 10162 (25%) patients having more than one uTI. In the adjusted model male sex was associated with a lower rate of any uTI (aHR: 0.94, p< 0.01), and age of 20-59 was associated with a 13% reduction in the rate of TI compared to < 20 years of age (20-59 years aHR 0.87, p< 0.01). Preserved immune function was associated with a reduced rate of TI compared to CD4 cell count < 200 cells/μL (CD4 200-350 cells/μL aHR 0.89, p< 0.01; CD4 > 350 cells/μL aHR 0.87, p< 0.01), whereas advanced clinical disease was associated with increased rate (WHO stage 3 aHR 1.10, p< 0.01; WHO stage 4 aHR of 1.21, p< 0.01). There was no relationship between uTI and mortality after adjusting for disease status and considering LTFU as a competing risk.
**Conclusions:** uTIs were frequent and associated with younger age, female gender and more advanced HIV. uTI did not predict survival when lost to follow-up was considered a competing risk for this association. Further evaluation of predictors of uTI and the links between uTI and clinical outcomes are needed to design targeted interventions.

*Presenting author email: lillian.brown@ucsf.edu*

**Background:** Retention in care is critical to the success of universal test and treat strategies. We sought to characterize predictors and barriers to retention within a streamlined model of care in a population-based universal test and treat trial.
**Methods:** Retention in care at one year (attending a follow-up visit or evidence of HIV care at another site within 90 days of scheduled 12-month visit) was measured among HIV-infected adults who linked to care following a multi-disease community health campaign in the SEARCH trial in rural Uganda and Kenya (NCT01864603). Patients received a streamlined care package consisting of appointment reminders and quarterly visits with patient-centered care providing reduced waiting and overall visit duration. Predictors of not being retained were estimated using Cox proportional hazards modeling with death as a competing risk.
**Results:** Among 5,429 HIV-infected adults (age≥15) who linked to care, 1,801 (33.2%) were male and 5,293 (97.5%) were stable residents residing in the community for >6 months in the last year. Overall 5,048 (93.0%) were in care one year after their first post-health campaign visit with 88.2% at their original clinic and 4.8% at an alternative site. One-year retention was 95.3% in patients in continuous care, 95.4% among those re-engaging, and 87.3% in patients newly linking to HIV care. Retention did not differ between stable and mobile residents (93.1% vs 91.2%, p=0.4), gender (92.3% men retained vs 93.4%, p=0.17), or pre-ART CD4 above vs below country treatment initiation guidelines (92.4% vs 93.2%, p=0.3). Younger patients (age 15-24 HR 3.3[95% CI 2.5-4.3]; age 25-29 HR 2.1[1.6-2.7]) and those newly linking or re-engaging who took >30 days to link (HR 1.4[1.1-1.7]) were more likely to be out of care at one year. Of those not retained, 1/3 dropped out within 30 days.
**Conclusions:** In this universal test and treat program that utilizes a streamlined care model, 93% were retained in care at one year, including those with high CD4, men, and mobile residents. Those taking longer to link, linking to care for the first time, and young adults are at increased risk for dropping out of care with highest risk immediately after linkage.

## TUPEB050

### RETENTION OVERTIME AND REASONS FOR STOPPING LIFELONG ANTIRETROVIRAL THERAPY IN A GROUP OF CAMEROONIAN PREGNANT AND BREASTFEEDING HIV-POSITIVE WOMEN INITIATING "OPTION B+" IN THE SOUTH-WEST REGION

P. Atanga[1,2], E. Achidi[3], H. Ndetan[4], H. Meriki[5], M. Hoelscher[2,6], A. Kroidl[2,6]
*[1]University of Buea, Department of Public Health and Hygiene, Buea, Cameroon, [2]University of Munich (LMU), Center for International Health, Munich, Germany, [3]University of Buea, Department of Medical Laboratory Science, Buea, Cameroon, [4]Parker University, Research Institute, Dallas, United States, [5]University of Bues, Department of Microbiology and Parasitology, Buea, Cameroon, [6]University of Munich (LMU), Department for Infectious Diseases and Tropical Medicine, Munich, Germany*
*Presenting author email: nji_atanga@yahoo.com*

**Background:** The uptake of lifelong antiretroviral therapy (ART) for HIV-positive pregnant and breastfeeding women has significantly increased with the introduction of the Prevention of Mother to Child Transmission Option B+. It is also expected to benefits the HIV-infected women, their exposed infants, uninfected male partners and the overall ART programme. However, these benefits hinges on adherence and long term retention in care which tends to vary with settings and overtime. We assess retention overtime and reasons for stopping lifelong ART in HIV-positive pregnant and breastfeeding women initiating option B+ in Cameroon.
**Methods:** We examined retention at 6 and 12 months after ART initiation between October 2013 and December 2014 in five health facilities in the Kumba Health District. During follow-up, women missing clinic appointments were traced by peer educators through phone calls and home visits. Tracing outcomes and reasons for stopping were documented.
**Results:** Overall, 268 women started option B+ during their current pregnancy or in breastfeeding, and 86(32.1%) appeared to have discontinued treatment during follow-up. Of these, 19(22.1%) were self-transferred to another ART clinic. For the remaining 67 clients, 2(3%) had died, 29(43.3%) were not traceable and 36(53.7%) had stopped treatment. The 247 women remaining in the analysis (excluding deaths and self-transferred), 13% discontinued treatment at or before 6months and cumulatively 21.1% at 12 months. Starting treatment in a small site with lone staff and younger age (< 25 years) were associated with treatment discontinuation.
The main reasons for stopping treatment were; denial of HIV status, stigma and discrimination in 19 cases (52.8%), religious reasons in 9 cases (25.0%), lack of transport for clinic visits in 4 cases (11.1%), and 4 women (11.1%) declined providing any reasons.
**Conclusions:** Retention on option B+ decreases overtime and varies with facilities with small sites with lone staff recording lower retention rates. Though same day initiation is necessary for the success of option B+, adequate preparation is necessary for treatment success. HIV status denial, stigma and discrimination and religious beliefs were top reasons for stopping treatment. Improved staffing and community interventions to track defaulters and reduce stigma and religious beliefs would improve retention.

## TUPEB051

### HIGH RATES OF LOSS TO FOLLOW-UP AMONG WOMEN ON OPTION B+ ATTENDING CARE IN URBAN KAMPALA, UGANDA

A. Kiragga, E. Katunguka, R. Mwonda, E. Nassuna, J. Kigozi
*Infectious Diseases Institute, Kampala, Uganda*
*Presenting author email: agnes.kiragga@gmail.com*

**Background:** The successful rollout of option B+, life long treatment for HIV+ pregnant women in sub-Saharan Africa is currently challenged with poor retention in care. Early drop out of care may compromise the health of mothers. We sought to quantify the amount of lost to follow-up among women receiving option B+.
**Methods:** Data was collected from 5 Kampala Council City HIV clinics supported by the Infectious Diseases Institute, Uganda. We followed up HIV+ pregnant women on ART under the Option B+ strategy since its roll out in 2012. Lost to follow-up was defined as having not seen in care within three months at time database closure.
**Results:** A total of 23319 patients were registered in care, and 3138(13.5%) were women on option B+ strategy. The median age of the women was 25(IQR: 22,30) and median CD4 cell count at entry was 447 cells/µL(IQR:284,625). The proportion of HIV+ women on option B+ increased from 0.4% in 2012 to 20% in 2015. The median days spent in care among the women on option B+ reduced from 182 days in Jul-Dec2012 to very early drop out in Jan-Jun 2015 (0 days).

| Year | Period | Number | Option B+ Mothers, n (%) | CD4 cells/µL at entry median (IQR) | Proportion of LTFUP among overall patients n (%) | Proportion of LTFUP among Option B+ patients n(%) | Days retained in care among patients LTFUp median(IQR) |
|---|---|---|---|---|---|---|---|
| 2012 | Jan - Jun | 2890 | 12 (0.4) | 289 (144,327) | 1556 (54.2) | 3 (25.0) | 825 (328,1191) |
| 2012 | Jul - Dec | 2365 | 100 (4.2) | 557 (366,686) | 1381 (58.4) | 67 (67.0) | 182 (0, 678) |
| 2013 | Jan - Jun | 3064 | 509 (16.6) | 459 (306,638) | 1658 (54.1) | 326 (64.0) | 86 (0, 381) |
| 2013 | Jul - Dec | 4435 | 379 (8.6) | 426 (228,634) | 2284 (51.5) | 226 (59.6) | 85 (0,399) |
| 2014 | Jan - Jun | 3410 | 673 (19.7) | 454 (278,639) | 1835 (53.8) | 401 (59.6) | 59 (0,208) |
| 2014 | Jul - Dec | 3243 | 674 (20.8) | 449 (295,600) | 1705 (52.6) | 419 (62.2) | 31 (0,153) |
| 2015 | Jan - Jun | 3912 | 791 (20.2) | 435 (278,614) | 1705 (43.6) | 402 (50.8) | 0 (0,53) |
| Total | | 23319 | 3138 (13.5) | 447 (284,625) | 12314 (52.0) | 1844 (58.8) | 35 (0,184) |

*[Table 1]*

**Conclusions:** These alarmingly high rates of LTFUp are critical in the success of the Option B+ strategy and denote. There is need for immediate strategies to ensure retention in care.

### PILOT STUDY TO RE-ENGAGE PATIENTS WHO DROPPED OUT OF ARV TREATMENT IN YUNNAN, CHINA

Y. Lao[1,2], J. Lou[1], X. Wu[3], J. An[1], T. Li[1], X. Dong[1], H. Li[1]
*[1]Yunnan AIDS Care Center, Kunming, China, [2]Yunnan Provincial Hospital of Infectious Disease, Kunming, China, [3]Honghe Prefecture Hospital of Infectious Disease, Mengzi, China*
*Presenting author email: laoyunfei@hotmail.com*

**Background:** Since in 2004 the establishment of China National Free Antiretroviral Therapy (ART) program in Yunnan Province, almost 70,000 people infected with HIV have entered treatment around the province. But the rate of drop-out is almost 11%. Failure to engage in care is associated with poorer health outcomes and increases the risk of further transmission. Therefore, understanding reasons for dropping-out and finding methods to re-engage into care are needed.
**Description:** The pilot project involved four counties in Yunnan. National ART Database was reviewed to develop a list of patients dropping out of care between 2004 and 2015. The clinical staff at the ART clinics worked with local CDC, township health center staff, and peer-volunteers to make contact with these patients either through phone or by home-visits. For these who gave consent, in-person interviews were conducted to understand their experiences in treatment, and their reasons for dropping out. Following the interview, counseling was given to the patients to re-start ART.
**Lessons learned:** Out of 485 patients that were identified as lost-to-follow-up through the national database, staff was able to get in contact with 173 (35.7%). Out of these, 130 (75.1%) completed the interview. Among these, 53% were aware that low adherence or stop taking the medicine can lead to bad health outcomes. Over 62% of the subjects said side-effect of the ARV was a reason for them to drop out. Schedule too busy or migrant work (28.7%) and self-assessment of better health (24.3%) were the next biggest reasons for dropping-out. After counseling with the clinical staff, 73 people (56.2%) have re-started treatment.
**Conclusions/Next steps:** Using information from treatment database in combination with efforts by local health workers, patients who had been lost-to-follow-up can be re-engaged. Re-engagement could help getting a proportion of these patients back into care. However, if only relying on the local health system, almost two-thirds of the patients still cannot be contacted. The results suggest that ARV adherence counseling and support services must be strengthened. Also, strengthening the linkage between ARV sites nationally could not only improve re-engagement of patients, but also make retention in care more accessible to these who are migrant workers.

## TUPEB053

### CLINIC AND COMMUNITY BASED FACTORS INFLUENCING PATIENT DIS-ENGAGEMENT FROM HIV CARE AND TREATMENT IN ZAMBIA

C. Mwamba[1], S.M. Topp[1,2], L.K. Beres[3], N. Padian[4], C.B. Holmes[1,3], E.H. Geng[4], I. Sikazwe[1]
*[1]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [2]James Cook University, College of Public Health, Medical and Veterinary Sciences, Townsville, Australia, [3]Johns Hopkins University, School of Public Health, Baltimore, United States, [4]University of San Francisco, San Fransisco, United States*
*Presenting author email: chanda.mwamba@cidrz.org*

**Background:** As Zambia scales-up HIV care and treatment, more focus is being placed on understanding and supporting retention in HIV-care. Despite strong efforts, substantial numbers of people leave or disengage from HIV-care and systematic evidence to explain the phenomenon remains sparse. Nested within a larger study of HIV care and treatment outcomes, this qualitative research sought to explore such patient disengagement.
**Methods:** In-depth interviews were conducted with a random sample of 17 disengaged (no presentation at clinic for >=90 days since last scheduled visit or 180 days since any clinic visit) male and female adults from four provinces. Sixteen focus group discussions were additionally convened with lay and professional health workers. Audio transcripts were translated, transcribed and uploaded to Nvivo QSR™ for thematic analysis incorporating largely inductive coding.
**Results:** At the clinic level, discussed factors influencing patient disengagement included perceived negative attitudes of health workers, intensified clinic visits for patient 'defaulters', and frustration with clinic processes - specifically loss of test results/medical records and long waiting times. Relative lack of privacy due to clinic structures and procedures also contributed, as PLHIV feared 'involuntary disclosure'. Within the community level, participants narrated livelihood constraints and economic costs of accessing treatment including time and transport costs. Participants also described negative 'myths' about anti-retroviral drugs. A profound fear of stigma associated with HIV and and life-long treatment persists and continues to impact treatment decisions.
**Conclusions:** Patient decisions to disengage from care are influenced by factors emanating from both the clinic and community domains. To effectively support retention in care of PLHIV, strategies must be developed to address: i) clinic service processes that impact waiting times and privacy, ii) the financial and logistical burden which static clinic-based care models create for patients, and iii) the continued social impact of community attitudes on PLHIV. Specifically, processes to engage communities in developing localised strategies to counter myths and stigma relating to patient treatment are required.

## TUPEB054

### HIV TREATMENT PROTOCOLS AND PERCEPTIONS OF THE 'IDEAL' PATIENT: IMPLICATIONS FOR LONG-TERM ENGAGEMENT IN CARE

S.M. Topp[1,2], C. Mwamba[2], L.K. Beres[3], N. Padian[4], I. Sikazwe[2], C.B. Holmes[2,3], E.H. Geng[4]
*[1]James Cook University, College of Public Health, Medical and Veterinary Sciences, Townsville, Australia, [2]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [3]Johns Hopkins University, School of Public Health, Baltimore, United States, [4]University of San Francisco, San Fransisco, United States*
*Presenting author email: globalstopp@gmail.com*

**Background:** With growing numbers HIV-infected individuals needing to access care and treatment, strategies to strengthen long-term engagement in care are critical. Nested in a 4-province study of HIV care and treatment outcomes, we examined how Zambian patients' and healthcare workers' (HCW's) perceptions of care and care-practices are influencing this engagement.
**Methods:** In-depth interviews were conducted with a stratified random sample of 75 adults across five patient categories: engaged in-care, pregnant in-care, disengaged, facility transfer, friend/family of deceased patient. Sixteen focus group discussions were also convened with lay and professional HCW serving the same catchment areas. Audio transcripts were translated, transcribed and uploaded to Nvivo QSR™ for inductive analysis.
**Results:** Patients and HCW had strong shared understanding of what constitutes a 'good patient'. For HCWs 'good patients' were characterised by their respect for staff and adherence to 'the rules' of visit and medication schedules stipulated by clinical protocols. HIV-patients similarly described 'good patients' as those who 'obey HCW' and 'follow the rules'. Despite this, HIV-patients and HCW reported logistical (e.g. time/distance to clinic) and interpersonal factors (e.g. patient-HCW clashes) that undermined patients' capacity to meet such requirements. This included frequent clashes between protocol-driven visit-schedules and HIV-patients' familial, livelihood or work commitments. Inability or unwillingness to adhere to schedules often resulted in HCW characterising patients as 'troublesome' or 'rude' which, combined with other points of conflict, led to breakdowns in trust and communication.
**Conclusions:** Despite widespread recognition of HIV-patients' varied socio-cultural and economic backgrounds, HCW in Zambia remain remarkably rigid in their characterisation of 'good' or 'bad' HIV-patients based in part on adherence to protocol-driven rules. In an era of rapidly increasing patient numbers, static facility-based care combined with inflexible application of protocols that are associated with a normative or 'ideal' patient, are likely undermining rather than encouraging long-term engagement in care.

## TUPEB055

### RETENTION IN CARE AMONG HIV-INFECTED PREGNANT MOTHERS ON LIFELONG ANTIRETROVIRAL THERAPY (ART) IN UGANDA

S. Muhumuza[1], E. Akello[1], C. Kyomugisha[1], I. Sebuliba[1], I. Lutalo[1], E. Kansiime[1], R. King[2], W. Bazeyo[1], C. Lindan[2]
*[1]Makerere University Kampala, School of Public Health, Kampala, Uganda, [2]University of California, Global Health Sciences, San Francisco, United States*
*Presenting author email: smuhumuza@musph.ac.ug*

**Background:** In an endeavour to improve maternal health and survival, as well as reduce vertical transmission of HIV in Uganda, lifelong ART is provided to all HIV-infected pregnant mothers (Option B+) irrespective of CD4 count or clinical stage. However, retention in care among HIV-infected pregnant mothers is unknown but suspected to be low. We evaluated retention in care and explored reasons why mothers drop out of care.
**Methods:** We performed a retrospective cohort analysis of data abstracted from health facility records of 2,169 pregnant mothers who had enrolled on ART between January and March 2013 in a representative sample of 145 health facilities in all 24 districts in the central region of Uganda. Using survival analysis, we calculated retention in care at 6, 12 and 18 months post-ART. To explore reasons why mothers drop out of care, we performed 21 in-depth interviews (IDIs) with mothers who

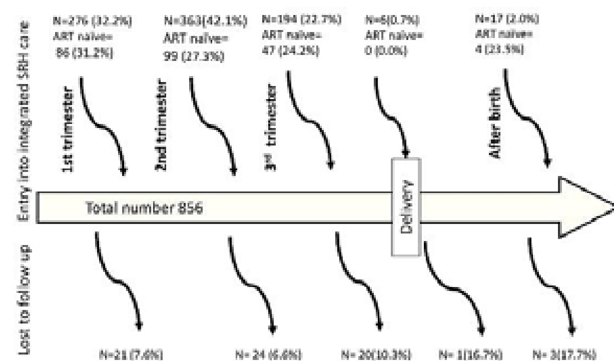
dropped out, 21 IDIs with mothers who were retained in care and 29 focus group discussions (FGDs) with peer mothers and village health team (VHT) members.
**Results:** The overall median follow-up time after enrolment on Option B+ was 20.2 months (IQR 4.2-22.5). The proportion of mothers retained in care at 6, 12 and 18 months post-ART was 74.2%, 66.7% and 62.0%, respectively. Retention in care at each time point varied considerably by health facility level and was highest among mothers seen at hospitals and lowest among those seen at lower level facilities (p< 0.05). Mothers who dropped out of care expressed concerns about fear of disclosure of HIV status and resulting stigma; insufficient partner support; difficulty with transportation to clinics; by poor provider attitudes and stock outs of ARV drugs. In addition, VHT members and peer mothers complained about inadequate support to track mothers in the community.
**Conclusions:** Retention in HIV care in this population is moderate. Poor provider attitudes, high levels of stigma and discrimination in the community, stock-outs of ARV drugs and barriers to transportation to clinics are some of the factors that could undermine the program and need to be addressed.

## TUPEB056

### DESCRIBING POINT OF ENTRY INTO CARE AND LOST TO PROGRAM IN A COHORT OF HIV-POSITIVE PREGNANT WOMEN IN A LARGE URBAN CENTRE IN UGANDA

F. Mubiru, A. Kiragga, S. Nakalema, H. Mackline, I. Kalule, R. Parkes Ratanshi, B. Castelnuovo
*Infectious Diseases Institute, Research, Kampala, Uganda*
*Presenting author email: mubiruf09@gmail.com*

**Background:** Published data from sub-Saharan Africa suggest high rates of lost to follow-up (LTFU) among women on prevention of mother-to-child (PMTCT) programs. At the Infectious Diseases Institute (IDI, Kampala, Uganda), an HIV centre with over 8,000 HIV-positive individuals enrolled, we started an integrated PMTCT-HIV integrated clinic where pregnant women receive both PMTCT and HIV care including the recommended WHO regimen (currently TDF+FTC+EFV).
**Methods:** We included women who became pregnant between 1/Jan/2012 and 1/Aug/2014. We used proportions to describe the point of entry into the integrated clinic (1st, 2nd, 3rd trimester, delivery, post-partum) and the magnitude of LTP. We used logistic regression methods to determine the characteristics associated with LTP including age, WHO stage, parity, CD4 count, ART status (ART-naïve vs on ART), and time on ART. LTFU was defined as being out of care for at least 3 months.
**Results:** 856 women were included in the analysis; median age was 31 years (IQR: 26-35); median CD4 count was 433 cells/μL (IQR: 301-638), 236 (27.6%) were ART naïve, 329 (39.5%) had >2 pregnancies. The figure shows the point of entry into integrated care and the time of LTP by gestation age and the proportion who were ART naive. Only 36.4% (86/236) of the women were enrolled in the first trimester. Overall 69 (8.1%) were LTP. In the multivariate analysis older women (OR: 0.96 per year increase, CI: 0.91-0.99, P=0.042) and women on ART at the time of pregnancy (0.52, CI: 0.31-0.88, P=0.015) were more likely not to be LTP.
**Conclusions:** As a result of integrated PMTCT and HIV services we observed a low rate of LTP; however our data suggests the need for interventions to enhance linkage of HIV positive women for prompt ART initiation and for increased retention in care of young and ART naïve women.



*[Point of entry into integrated care and the time of LTP by gestation age]*

## TUPEB057

### INVESTIGATING ASSOCIATIONS BETWEEN USE OF CHEMSEX DRUGS AND HIV CLINIC ATTENDANCE AMONG GAY AND BISEXUAL MEN IN THE UK

A. Howarth[1], F. Burns[1], C. Sabin[2], V. Apea[3]
*[1]University College London, Centre for Sexual Health and HIV Research, London, United Kingdom, [2]University College London, HIV Epidemiology and Biostatistics Group, London, United Kingdom, [3]Barts Health NHS Trust, London, United Kingdom*
*Presenting author email: alison.howarth@ucl.ac.uk*

**Background:** The benefits of HIV treatment are only realised when people are aware of their HIV status and engaged in care. There are limited data on the association between engagement in HIV care and use of "chemsex" drugs among gay and bisexual men in the UK. We investigated this as part of the REACH project.
**Methods:** We conducted a cross-sectional survey among patients attending seven HIV clinics in London (May 2014-August 2015). We recruited regular attenders (RA: all appointments attended in past year), irregular attenders (IA: 1+ appointments missed in past year) and non-attenders (NA: attended in past year after absence of 1+year). The sample was stratified to over-represent IA and NA. We selected men who identified as gay or bisexual.
We examined the association between socio-demographic, economic and HIV-related factors and use of crystal methamphetamine (crystal meth), gamma-butyrolactone (GBL) and mephedrone. We used binary logistic regression to examine the association between use of chemsex drugs and HIV clinic attendance, adjusting for associated variables.
**Results:** Gay and bisexual men represented 58.0% (570/983) of the sample (median age=45 years; 76.8% white; 59.0% RA, 26.7% IA, 14.4% NA). At survey completion, 87.5% were on ART and 19.5% had a detectable VL (>50 copies/ml). In the past year, 22.8% reported using crystal meth; 23.7% GBL; and 31.4% mephedrone.
Using crystal meth was associated with a detectable viral load (27.8% vs 17.2%), GBL with being younger (mean age=40.4 vs 46.7 years) and more recently diagnosed (mean=9.3 vs 12.2 years), and mephedrone with being younger (39.7 vs 47.7 years), more recently diagnosed (9.0 vs 12.7 years) and ART naïve (14.5% vs 6.0%), (all p< .01).
Men were significantly more likely (p< .05) to be IAs than RAs if they had used crystal meth (33.1% vs 17.6%; aOR=1.93 [95%CI: 1.13-3.29], p=.024) or GBL (32.4% vs 19.4%; aOR=1.82 [1.41-2.33], p=.001) but not mephedrone (37.2% vs 27.9%; aOR=1.73 [0.97-3.11], p=.06). Use of chemsex drugs was not significantly more likely among NAs than RAs.
**Conclusions:** Use of chemsex drugs is associated with irregular clinic attendance. This should be considered when developing interventions to improve engagement in HIV care among gay and bisexual men.

## TUPEB058

### RISK OF CLINICAL PROGRESSION AMONG PATIENTS RE-ENTERING IN CARE AFTER BEING LOST

C. Mussini[1], A. Mammone[2], G. Marchetti[3], M. Lichtner[4], A. De Luca[5], G. Lapadula[6], S. Lo Caputo[7], A. Antinori[2], A. d'Arminio Monforte[3], E. Girardi[2], ICONA Foundation Study
*[1]Infectious Disease Clinic, University of Modena and Reggio Emilia, Modena, Italy, [2]National Institute for Infectious Diseases 'L. Spallanzani', Rome, Italy, [3]Clinic of Infectious Diseases, San Paolo Hospital, University of Milan, Milan, Italy, [4]Infectious Diseases Unit, SM Goretti Hospital, Latina, Italy, [5]Infectious Diseases Unit, Siena University Hospital, Siena, Italy, [6]Division of Infectious Diseases, San Gerardo Hospital, Monza, Italy, [7]Department of Infectious Diseases, University of Bari, Bari, Italy*
*Presenting author email: antonella.darminio@unimi.it*

**Background:** A non negligible proportion of patients with HIV may re-engage in care after being lost at different steps of the cascade of care. We evaluated in the Icona cohort the risk of clinical progression of patients re-entering in care.
**Methods:** Persons enrolled in 1997-2014 were included. Patients were considered lost to care if they had no clinical visit for at least one year. CD4-cell count and HIVRNA before and after the gap in care (GIC) were evaluated by paired t-test or by McNemar's test. A Poisson regression analysis was used to investigate the association between having a gap in care and the risk of clinical events (AIDS, serious non-AIDS events (malignancies, severe infections, ESKD, cardiovascular events, ESLD) hospitalization or death).
**Results:** 2,708 (21.8%) out of 12,429 patients were lost to care; the incidence rate ranged from 12.3 in 1998 to < 1 per 100 PYFU in 2014. 433 patients (16.7%) re-entered the cohort after a mean gap in care of 2.8+/-2 years.
At last visit before GIC, median CD4 were 551+/-323 cells/uL while after re-entering care this value decreased to 444+/-359 (p< 0.001). The proportion of patients having CD4-cell count< 200 increased from 10.7% before to 25% after re-entering

in care (p< 0.001). An increase was observed in median HIVRNA (4,103 before vs 11,030 copies/mL after); also the proportion of patients with>100000 copies/mL doubled after re-entering in care (8.8% vs 15.2%, p=0.028).
Clinical events occurred in 100 patients (23%) within 6 months after re-entering in care: 9 (2%) died, 22 (5%) developed AIDS, 21 (5%) a serious non-AIDS event and 48 (11%) had an hospitalization. In a multivariable model adjusted for gender, risk factors, late presentation, HCV-coinfection and current CD4-cells count, patients with a GIC had an increased risk of clinical events (RR=2.36, 95%CI:2.06-2.71, p< 0.001).
**Conclusions:** Patients re-entering care after a gap of at least one year have an increased risk of presenting with a clinical event and viro-immunological deterioration and an increased potential for viral transmission linked to the increase in HIV viral load. HIV clinical cohorts data may contribute to the monitoring of HIV continue of care at national level.

## TUPEB059

### Lottery incentives to improve adherence to antiretroviral (ARV) drugs: Evidence from a randomized controlled trial in Uganda

S. Linnemayr[1], C. Stecher[2], B. Mukasa[3]
*[1]RAND Corporation, ESS, Los Angeles, United States, [2]UCLA, Economics, Los Angeles, United States, [3]Mildmay Uganda, Kampala, Uganda*
*Presenting author email: slinnema@rand.org*

**Background:** Innovative approaches are needed to improve adherence to ARV medication in sub-Saharan Africa to maintain HIV patients' health and avoid drug resistance. The objective of our study is to evaluate whether small prizes allocated by a drawing conditional on timely clinic visits and high levels of pill-taking can increase ARV adherence.
**Methods:** We implemented a randomized trial beginning in March 2013 for 20 months among 155 HIV-positive men and women aged 19-78 in Kampala, Uganda who were randomized to 1 of 2 intervention groups or a control group. Prizes were awarded to participants in the first intervention group conditional on timely clinic visits; eligibility in the second group was based on high adherence measured by medical event monitoring system (MEMS) caps. Upon drawing a winning number with a chance of 1:6, participants were given a prize valued at about 6,000 Ugandan shillings (≈US $2). The control group was not eligible to participate in the prize drawings.
**Results:** MEMS-caps measured 20-month mean ARV adherence was 8.5 percentage points higher in the pooled intervention groups (82.7%, 95% CI, 79.2 - 86.2) than in the control (74.3%, 95% CI, 67.5 - 81.1), and the pooled intervention groups were more likely to maintain 90% or higher adherence (OR 2.3, 95% CI, 1.2 - 5.4) than in the control group. Assignment to the directly incentivized intervention group was associated with a higher likelihood of at least 90% adherence relative to the control group (OR 2.5) than the intervention group eligible based on timely clinic visits (OR 1.7), but this differential treatment impact was not statistically significant (p=0.16). In the directly incentivized treatment group, mean adherence improvements persist through six months post-intervention (11.6% higher than control, 95% CI, 1.0 - 22.3), indicating a sustained effect of the intervention.
**Conclusions:** The promising results that lottery incentives worth only approximately US $2 resulted in a sizeable increase in ARV adherence among adults in HIV care in Uganda deserve further research, in particular into the appropriate frequency of rewards and the prize amounts that optimally support high adherence while also being sustainable.

## TUPEB060

### 6-months treatment outcomes of patients initiating ART under the WHO Test & Treat approach

B. Kerschberger[1], S. Mazibuko[2], I. Zabsonre[1], R. Teck[3,4], S. Kabore[1], D. Etoori[1], M. Ndlangamandla[1], B. Rusch[3], I. Ciglenecki[3]
*[1]Médecins Sans Frontières (OCG), Mbabane, Swaziland, [2]Swaziland National AIDS Program (SNAP), Ministry of Health, Mbabane, Swaziland, [3]Médecins Sans Frontières (OCG), Geneva, Switzerland, [4]Medecins Sans Frontieres, Southern Africa Medical Unit (SAMU), Cape Town, South Africa*
*Presenting author email: benadi11@yahoo.de*

**Background:** WHO recommends anti-retroviral therapy (ART) for all people living with HIV regardless of CD4 count, known as Test and Treat (T&T). However, T&T is feared to lead to inferior treatment outcomes in patients initiating ART at high CD4 counts, specifically in men. We report on early outcomes of one of the first T&T demonstration projects in the public health sector in Sub-Saharan Africa.
**Methods:** This is a prospective cohort of non-pregnant patients (aged ≥16 years) who initiated ART in 9 public health facilities in the rural Nhlangano health zone in Swaziland, from October 2014 to April 2015. Follow-up time was until the occurrence of an unfavourable treatment outcome (death/lost-to-follow), or censored at date of transfer-out and database closure (September 2015). Kaplan-Meier estimates described 6-months retention on ART rates, and Cox proportional hazard models assessed predictors of the unfavourable outcome while adjusting for baseline characteristics (gender, CD4 count, WHO stage, same-day treatment initiation, newly diagnosed/ known HIV+ case, body-mass index, baseline TB status).
**Results:** Of 625 patients initiated on ART, 427 (68.3%) were females, the median age was 33 (IQR 27-42) years and 302 (48.3%) were newly diagnosed with HIV. At ART initiation, 280 (44.8%) patients had a CD4 count ≤349; 159 (25.4%) between 350-499; 182 (29.1%) ≥500 and 4 (0.6%) had missing value. The overall crude six-month retention on ART was 86.8% and it was similar between women (87.0%) and men (86.2%) (p=0.74). Retention was higher in the CD4 strata 350-499 (89.2%) and CD4≥500 (90.0%) when compared to CD4≤349 (83.5%) (p=0.05). In multivariate analysis, there was not a difference in outcomes by gender (women: adjusted Hazard Ratio [aHR] 1.08, 95%CI 0.68-1.72). However, higher CD4 levels (CD4 350-499: aHR 0.75,95%CI 0.42-1.31; CD4≥500: aHR 0.71, 95%CI 0.40-1.24) showed a trend of decreased probability, and combined WHO stage III/IV (aHR 2.35, 95%CI 1.41-3.89) and same-day ART initiation (aHR 1.68, 95%CI 1.02-2.79) an increased probability of an unfavourable outcome.
**Conclusions:** Patients with high baseline CD4 counts and both gender had good early treatment outcomes when ART was started under the T&T approach. Program managers in similar settings should not fear to quickly adopt T&T.

## TUPEB061

### Re-initiation of antiretroviral therapy (ART) following treatment interruption among HIV-positive people who inject drugs (PWID)

W.G. Small[1], R. McNeil[1], M.J. Milloy[1], L. Maher[2], T. Kerr[1]
*[1]B.C. Centre for Excellence in HIV/AIDS, Faculty of Health Sciences, Simon Fraser University, Vancouver, Canada, [2]Kirby Institute, University of New South Wales, Sydney, Australia*

**Background:** HIV-positive people who inject drugs (PWID) often experience interruptions in antiretroviral therapy (ART), contributing to poor treatment outcomes among this population. ART re-initiation is critical to reducing HIV/AIDS-associated morbidity and mortality, and maximizing the preventive potential of HIV Treatment as Prevention (TasP) initiatives among PWID. We undertook this ethno-epidemiological study to explore individual, social, and structural influences on ART re-initiation among PWID in a setting with a community-wide TasP initiative (Vancouver, Canada).
**Methods:** Through a linkage between provincial pharmacy records and a prospective cohort comprised of HIV-positive people who use drugs, we recruited 39 participants who experienced ART interruptions (defined as ≥30 days without refilling an ART prescription) within the previous two years to participate in semi-structured qualitative interviews. We employed deductive and inductive methods of analysis to examine influences on ART re-initiation among a sub-sample of 24 PWID who had resumed treatment.
**Results:** While concerns regarding health-related impacts of ART interruptions (e.g., HIV disease progression) led some participants to re-initiate treatment, others resumed ART therapy as a result of efforts by a physician or a nurse, including outreach activities. Numerous participants re-initiated ART during periods of hospitalization or incarceration. Re-initiation often involved efforts to address forces that resulted in treatment interruptions, and managing these obstacles was important for participants' willingness to begin ART again. These efforts included changing to different ART regimens with simpler dosing requirements and/or fewer side effects, and altering dispensing arrangements to receive medications daily, observed ther-

apy and co-dispensation of ART with methadone. Similarly, re-initiation sometimes coincided with increased stability in participants' lives, stemming from reduced drug use or obtaining housing, which reduced potential for non-adherence.
**Conclusions:** Our findings illustrate how extra-individual forces influence ART re-initiation among PWID, and have the potential to inform targeted interventions to improve treatment retention for this key population. Programmatic interventions (e.g., housing, maximally assisted therapy, ART co-dispensation with methadone) have potential to engage PWID and promote re-initiation of ART. Barriers to adherence can be addressed as ART is re-initiated, and the process may provide an opportunity to optimize dispensing and care arrangements to minimize potential for further treatment interruptions.

## TUPEB062

### FACTORS ASSOCIATED TO ATTRITION AT THE ART PROGRAM IN MOZAMBIQUE

E. Karajeanes[1], O. Augusto[2], M.G. Lain[3], S. José[4], J. Pitta[5], N. Calú[2], S. Agostinho[6], V. Chavane[3], J. Sacarlal[2], P. Vaz[5]
*[1]Ariel Glaser Foundation, Maputo, Mozambique, [2]Faculdade de Medicina UEM, Maputo, Mozambique, [3]Fundação Ariel Glaser Contra SIDA Pediátrico, Maputo, Mozambique, [4]Direcção Provincial de Saúde Maputo, Maputo Provincia, Mozambique, [5]Fundação Ariel Glaser contra SIDA Pediátrico, Maputo, Mozambique, [6]Direcção Provincial de Saúde Cabo Delgado, Maputo, Mozambique*
*Presenting author email: ekarajeanes@arielglaser.org.mz*

**Background:** In Mozambique, 497.455 individuals initiated ART in 2013. Retention remains the main challenge despite efforts to provide life-saving therapy. High rates of lost-to-follow up (LTFU) characterize the Mozambican ART program and reached 30% in 2013. In this study we explored the clinical and sociodemographic factors associated to attrition in Maputo (MP) and Cabo Delgado (CD) provinces from January 2012 to December 2013.
**Methods:** This was a retrospective analysis of secondary data from patients on ART extracted from an electronic database. Risk factors were evaluated by data comparison from LTFU to patients that remained in care. Descriptive analysis was performed based on clinical and sociodemographic characteristics, and factors associated to LTFU assessed through uni- and multivariate logistic regression analysis. Statistical analysis was performed using STATA 13. Study was approved by the bioethics committee of the Faculty of Medicine of UEM.
**Results:** Of the 46123 patients who initiated ART, 7.5%(3451) were children with a median age at ART initiation of 4.1yrs (IQR 1.6-8.3) for MP and 2.5yrs (IQR 1.1-6.3) in CD. In total 23% (10639) were LTFU. Of the LTFU patients, 52% and 48% occurred in MP and CD, where the LTFU rate was 15.9 and 40.1 per 100pyr, respectively. Significantly higher rates were observed in male patients in both provinces (20.6 vs 13.9 per 100pyr, p< 0.001 and 41.3 vs 39.5 per 100pyr, p< 0.030). Male gender and living in rural area where factors associated to LTFU in both provinces. Education, being single, WHO stages II-IV at ART initiation and ART initiation in 2012 were factors associated to LTFU in MP. Immunosuppression and ART initiation in 2013 were associated to LTFU in CD. In children LTFU rate was 16.4/100pyr (CI95%:14.9-18.1) in MP and 44.5/100pyr (CI95%: 40.6-48.6) in CD. In both provinces, factors associated to LTFU were advanced disease staging [CD=RR1.51(1.09-2.10) p< 0.001 and MP= RR1.91 (1.35-2.71)p< 0.001] and age ≤2yrs [CD=RR1.43(1.15-1.76) p< 0.001 and MP=RR1.6(1.28-2.08)p< 0.001].
**Conclusions:** Our results identified key factors associated to LTFU such as education, gender and advanced disease staging in general population, and young children, showing the need for strategic directed interventions that would prevent and/or timely identify potential losses.

## TUPEB063

### PSYCHIATRIC DISORDER, SUBSTANCE ABUSE AND DISTRESS DURING THE FIRST SIX MONTHS OF EARLY ANTIRETROVIRAL TREATMENT

J. Joska[1], C. Mellins[2], R. Robbins[2], H. Gouse[1], C.-S. Leu[2], M. Henry[1], L. Myer[3], D. Stein[1], R. Remien[2]
*[1]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa, [2]New York State Psychiatric Institute and Columbia University, New York, United States, [3]University of Cape Town, Public Health, Cape Town, South Africa*
*Presenting author email: john.joska@uct.ac.za*

**Background:** Individuals initiating antiretroviral treatment (ART) experience high rates of psychiatric disorders and psychological distress, affecting many health-related outcomes (retention in care, virological control, quality of life). It is not clear whether these rates subside as individuals link to services, accept ART, and adjust to living with HIV. We examined whether psychiatric disorders, substance/alcohol use problems and psychological distress would diminish in a significant number of individuals six months after entering care and initiating ART.
**Methods:** IsiXhosa-speaking, Black South African HIV+ adults eligible for ART were enrolled into an ART adherence intervention trial and completed baseline (n=454) and six-month follow-up (n=343) assessments, which included the Kessler-10 and Substance Abuse and Mental Illness Symptoms Screener (SAMISS). Generalized estimating equations were used to examine changes in psychiatric and substance/alcohol problems status from baseline to follow-up.
**Results:** At baseline, 56.4% screened positive for a substance/alcohol problem, and 41.7% screened positive for a psychiatric condition. Using a cut-off score of ³16 on the K10, 35.2% reported at least mild psychological distress. At follow-up, 34.3% screened positive for a substance/alcohol use problem, 0% screened positive for a psychiatric condition, and only 12.3% had a K10 score of ³16. When controlling for baseline gender, age, CD4 count, and TB status, analysis indicated that participants were significantly less likely to screen positive for an alcohol/substance problem (OR=.28,95%CI=[0.19, 0.40],p< 0.001), and have a score of ³16 on the K10 (OR=.41, 95%CI=[0.32,0.52],p< 0.001) at follow-up (note: Odds Ratios not available when rate is 0% as with psychiatric conditions).
**Conclusions:** High rates of psychiatric disorders, substance/alcohol problems and psychological distress present in individuals initiating ART may be the result of a recent HIV diagnosis and or other life stressors. Following ART counseling, ART initiation and linkage to HIV services, the rates of substance/alcohol problems significantly dropped, particularly for psychiatric disorders. Rates of at least mild psychological distress also substantially abated. These findings suggest that ART counseling may play a substantially more important and broader role in recently diagnosed and treated HIV patients. ART counselors may greatly benefit from increased training and supervision to address mental health and substance use problems.

### NATIONAL LABORATORY DATA TO ASSESS RETENTION IN CARE AFTER CLINIC TRANSFER IN SOUTH AFRICA

I. Bassett[1,2,3], M. Huang[2,4], C. Cloete[5], S. Candy[6], J. Giddy[5], S. Frank[2,4], K. Freedberg[3,7,8], E. Losina[2,3,9], R. Walensky[3,7,10], R. Parker[2,3,11]
*[1]Massachusetts General Hospital, Department of Medicine/Division of Infectious Disease, Boston, United States, [2]Medical Practice Evaluation Center, Department of Medicine, Massachusetts General Hospital, Boston, United States, [3]Harvard University Center for AIDS Research (CFAR), Boston, United States, [4]Massachusetts General Hospital, Division of General Medicine, Boston, United States, [5]McCord Hospital, Durban, South Africa, [6]National Health Laboratory Service (NHLS), Johannesburg, South Africa, [7]Massachusetts General Hospital, Medical Practice Evaluation Center, Department of Medicine/Division of Infectious Disease, Boston, United States, [8]Harvard T.H. Chan School of Public Health, Departments of Epidemiology and Health Policy and Management, Boston, United States, [9]Brigham and Women's Hospital, Division of Rheumatology, Department of Medicine, and Department of Orthopedic Surgery, Boston, United States, [10]Brigham and Women's Hospital, Division of Infectious Disease, Boston, United States, [11]Biostatistics Center, Massachusetts General Hospital, Boston, United States*
*Presenting author email: ibassett@partners.org*

**Background:** PEPFAR funding changes have led to HIV clinic closures and patient transfers to government-funded, community-based clinics in South Africa. Data on retention in care following such transfers are limited.
**Methods:** All adults (≥18y) on ART who visited a PEPFAR-funded hospital-based HIV clinic in Durban from March-June 2012 were transferred to community-based clinics. As a proxy for retention in care, we used CD4 count or viral load (VL) follow-up in the National Health Laboratory Services (NHLS) centralized data warehouse (CDW). The NHLS provides laboratory services to >80% of South Africa. Deaths were ascertained from the National Population Registry. We matched patient records from the hospital-based HIV clinic with CDW data to estimate the proportion of patients with

a CD4/VL record in the CDW during the year before transfer. We then evaluated whether patients had a post-transfer CD4/VL documented at another facility within 2 years. Among those with a matched value pre-transfer, we assessed predictors of not having post-transfer laboratory data in the CDW using multivariable logistic regression.
**Results:** Of 3,905 patients transferred, 59% were female and median age was 39 years (IQR 34-46). 3,469 (89%) patients had at least one matched pre-transfer CD4/VL in the CDW. Excluding 270 participants who either died within 9 months of transfer or transferred to a private clinic, 3,635 patients were assessed for post-transfer matching, of whom 2,384 (66%) had a post-transfer laboratory test from another facility. Of those surviving who had a pre-transfer matched record (3,228 patients), being male (aRR 1.2, 95% CI 1.0-1.3) and shorter ART duration at transfer (≤ 3 months, aRR 1.5, 95% CI 1.1-2.1; 3 months - 1 year, aRR 1.3, 95% CI 1.1-1.5, each compared to >1 year) were predictors of not having a post-transfer record in the CDW.
**Conclusions:** Two-thirds of patients had evidence of a post-transfer visit to another facility after closure of a large South African HIV clinic. Males and those with shorter ART duration at transfer were at highest risk for lacking follow-up laboratory data. As PEPFAR-funded clinics close, national data sources can be used to evaluate the long-term patient care trajectories within public clinics.

## TUPEB065

### LOW RETENTION OF PATIENTS IN ANTIRETROVIRAL TREATMENT DURING RECENT EBOLA OUTBREAK IN CONAKRY

J.D.A. Ndawinz[1], P. Yaradouno[2], M. Cissé[3], C.T. Sidibé[4], E. Guillard[1], G. Breton[1], W. Ameyan[5]
*[1]NGO SOLTHIS, Paris, France, [2]NGO SOLTHIS, Conakry, Guinea, [3]Hôpital National Donka, Conakry, Guinea, [4]Programme National de Prise en Charge Sanitaire et de Prévention des IST/VIH/SIDA, Conakry, Guinea, [5]SOLTHIS NGO, Freetown, Sierra Leone*
*Presenting author email: medical-officer.sl@solthis.org*

**Background:** Rapid transmission of the Ebola virus, the associated high mortality rate and the concentration of health resources towards the fight against the recent Ebola epidemic have disrupted the health-care system, undermining efforts made in other health programs. We analysed the impact of epidemic on retention of people living with HIV (PLWH) in antiretroviral treatment (ART) care in Conakry, where 75% of people receiving ART in Guinea live.
**Methods:** The nationwide database with aggregate number of PLWH receiving ART and database with repeated visits of PLWH receiving ART during 2014-2015 at Donka national hospital (DNH) in Conakry were used. DNH is the largest HIV facility in Guinea and hosted one of the Ebola treatment centres. To increase sensitivity of the epidemic on continuity of HIV care, a patient was defined as not retained in ART care if they did not attend the last scheduled visit at least 30 days after a given time point. Kaplan-Meier estimates of retention were compared between groups. Cox models were used to identify factors associated with retention in ART care.
**Results:** In 2014, the number of PLWH receiving ART in Conakry increased from 16,400 to 19,400 between January and August and then decreased to 18,600 in November, while the cumulative number of PLWH receiving ART outside Conakry increased from 5,500 to 7,300. At DNH, 13,939 PLWH including 63% of women received ART from January 2014 to June 2015 during a total of 44,518 visits. The median duration of retention in ART care was longer among PLWH who initiated ART before the Ebola outbreak compared to PLWH who initiated ART during the Ebola epidemic (9.4 versus 5.9 months; p< 0.001). In multivariate analysis, initiating ART during the Ebola epidemic versus before (adjusted hazard risk (aHR)=2.56; p< 0.001) and be followed in a pediatric ward (aHR=1.3; p=0.004) or in a general medicine ward (aHR=1.55; p< 0.001) increased the risk of not being retained in ART care.
**Conclusions:** The number of people receiving ART declined during the recent Ebola epidemic in Conakry. This decrease is likely due to the quality of healthcare provision available. This study will contribute to improve epidemics preparedness.

## TUPEB066

### SOCIAL DETERMINANTS OF HEALTH AND RETENTION IN HIV CARE IN A CLINICAL COHORT IN ONTARIO, CANADA

B. Rachlis[1,2], A.N. Burchell[2,3,4], S. Gardner[5], L. Light[1], J. Raboud[5,6], T. Antoniou[3,4], J. Bacon[1], A. Benoit[2,7], C. Cooper[8], C. Kendall[9,10], M. Loutfy[2,7,11], W. Wobeser[12,13], F. McGee[14], A. Rachlis[11,15], S.B. Rourke[1,3,16], Ontario HIV Treatment Network Cohort Study
*[1]Ontario HIV Treatment Network, Ontario HIV Cohort Study, Toronto, Canada, [2]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [3]St. Michael's Hospital, Li Ka Shing Knowledge Institute, Toronto, Canada, [4]University of Toronto, Department of Family and Community Medicine, Toronto, Canada, [5]University of Toronto, Division of Biostatistics, Toronto, Canada, [6]University Health Network, Toronto General Research Institute, Toronto, Canada, [7]Women's College Hospital, Women's College Research Institute, Toronto, Canada, [8]Ottawa Hospital Research Institute, Ottawa, Canada, [9]Bruyere Research Institute, Ottawa, Canada, [10]University of Ottawa, Department of Family Medicine, Ottawa, Canada, [11]University of Toronto, Department of Medicine, Toronto, Canada, [12]Queen's University, Department of Medicine, Kingston, Canada, [13]Hotel Dieu Hospital, Kingston, Canada, [14]Ontario Ministry of Health and Long Term Care, AIDS Bureau, Toronto, Canada, [15]Sunnybrook Health Science Centre, Toronto, Canada, [16]University of Toronto, Department of Psychiatry, Toronto, Canada*
*Presenting author email: srourke@ohtn.on.ca*

**Background:** Continuous HIV care supports antiretroviral therapy initiation and adherence, and prolongs survival. We investigated the association of social determinants of health (SDH) and subsequent retention in HIV care in a clinical cohort in Ontario, Canada.
**Methods:** The Ontario HIV Treatment Network Cohort Study (OCS) is a multi-site cohort of patients at 10 HIV clinics. Data were collected from medical charts, interviews, and via record linkage with the provincial public health laboratory for viral load tests. For participants interviewed in 2009, we used three category multinomial logistic regression to identify predictors of retention in 2010-2012, defined as (1) continuous care (≥2 viral loads ≥90 days in all years; reference category); (2) discontinuous care (only 1 viral load/year in ≥1 year); and (3) a gap in care (≥1 year in 2010-2012 with no viral load).
**Results:** In total, 1838 participants were included. In 2010-2012, 71.7% had continuous care, 20.9% had discontinuous care, and 7.5% had a gap in care. Discontinuous care in 2009 was predictive (p< 0.0001) of future retention. SDH associated with discontinuous care in 2010-2012 were hazardous drinking (vs. none; Adjusted Odds Ratio, 95% Confidence Interval: 1.4, 1.1-1.8) and non-injection drug use (vs. no drug use; 1.4, 1.0-2.0). Indigenous ethnicity (vs. White) was positively associated with experiencing discontinuous care (1.9, 1.3-2.8). Participants who were 35-49 (0.6, 0.4-0.9) or >50 (0.6, 0.4-0.9) years of age (vs. < 35), who immigrated ≤ 10 years ago (vs. Canadian-born; 0.4, 0.2-0.8), and who were not in the labour force (0.5, 0.3-0.7) or on disability (vs. being employed; 0.7, 0.5-0.9) were less likely to experience discontinuous care. Being a heterosexual male (2.4, 1.4-4.4) was associated with having a gap in care compared to men who have sex with men. Participants who were 35-49 (0.4, 0.3-0.8) or >50 (0.3, 0.1-0.5) and married (vs. single; 0.6, 0.4-0.9) were less likely to experience a gap in care.
**Conclusions:** Various social determinants of health were associated with retention. Care discontinuity was highly predictive of future gaps. Targeted strategic interventions that better engage those at risk of suboptimal retention merit exploration.

# INDICATORS OF QUALITY OF CARE

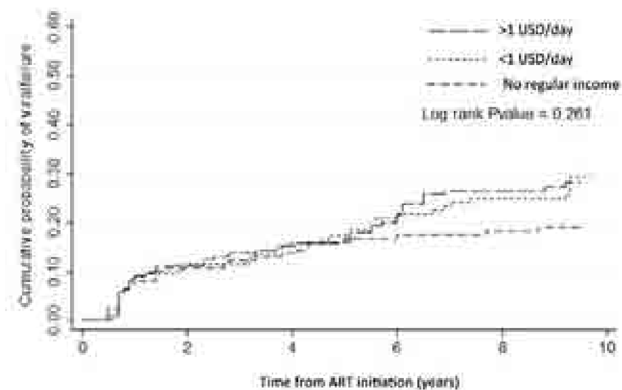
## TUPEB067

### SOCIOECONOMIC POSITION IS UNRELATED TO SURVIVAL AND VIROLOGIC OUTCOMES IN A TEN-YEAR FOLLOW-UP COHORT OF UGANDAN PATIENTS RECEIVING ANTIRETROVIRAL THERAPY

A. Flynn[1,2], G. Anguzu[1], F. Mubiru[1], A. Kiragga[1], M. Kamya[3], J. Wayama[1], J. Rhein[2], D. Meya[1,2], D. Boulware[2], A. Kambugu[1], B. Castelnuovo[1]
*[1]Infectious Diseases Institute, Kampala, Uganda, [2]University of Minnesota, Minneapolis, United States, [3]Makerere University College of Health Sciences, Kampala, Uganda*
*Presenting author email: apgflynn@gmail.com*

**Background:** Substantial evidence links low socioeconomic position with negative disease outcomes in various populations and settings. As ART access improves and HIV has become a chronic disease, differential outcomes are increasingly observed between patients of high and low socioeconomic position. We investigated if low socioeconomic position predicts mortality and HIV viral failure among individuals

receiving ART at an urban HIV clinic in Kampala, Uganda.
**Methods:** We enrolled 559 HIV-positive adults starting ART in a prospective cohort from 2004-2005 and followed them for 10 years. Upon enrollment we collected baseline demographic and clinical data and we measured socioeconomic position by assessing employment status, monthly household income, education level and housing description (to measure wealth). Follow-up visits, including laboratory testing, were completed every 6 months. Viral failure was defined as two consecutive measurements greater than 1000 copies/mL or a single measurement greater than 5000 copies/mL when a second measurement was not available. We used Cox regressions to assess if indicators of low socioeconomic status were associated with increased mortality or viral failure.
**Results:** 127/559 participants died (23%). We observed no independent associations between any socioeconomic indicator and mortality after controlling for clinical stage and CD4 count at presentation. 166/472 (35%) experienced viral failure. We observed no independent associations between any socioeconomic indicator and viral failure after controlling for clinical stage and CD4 count at presentation. There was no difference in the cumulative probability of viral failure when subjects were grouped by education level or monthly income (Figure).
**Conclusions:** In our cohort of HIV-infected Ugandan adults receiving ART we observed no significant differences in 10-year survival or virologic outcomes that could be attributed to household income, employment status, level of education or housing description. These results are encouraging for free ART programs that predominantly serve patients of low socioeconomic position.



*[Figure. Viral failure among patients receiving ART grouped by monthly household income]*

# ACROSS THE CASCADE FROM HIV TESTING TO CARE AND TREATMENT TO RETENTION

*[1]University of British Colombia, Faculty of Medicine, Vancouver, Canada, [2]Vancouver Coastal Health Authority, Vancouver, Canada, [3]Oak Tree Clinic, BC Women's Health Centre, Vancouver, Canada, [4]Division of Infectious Diseases, University of British Colombia, Department of Medicine, Vancouver, Canada, [5]Faculty of Health Sciences, Simon Fraser University, Burnaby, Canada, [6]British Colombia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [7]University of Victoria, Victoria, Canada, [8]Division of AIDS, University of British Colombia, Vancouver, Canada, [9]McMaster University, Department of Infectious Diseases, Hamilton, Canada, [10]Factor-Inwentash Faculty of Social Work, University of Toronto, Toronto, Canada, [11]Women's College Research Institute, Women's College Hospital, Toronto, Canada, [12]McGill University, Department of Family Medicine, Montreal, Canada, [13]Chronic Viral Illness Service, McGill University Health Centre, Montreal, Canada, [14]Management and Evaluation, University of Toronto, Department of Medicine and Institute of Health Policy, Toronto, Canada*
*Presenting author email: genevieve.kerkerian@gmail.com*

**Background:** In North American settings, women are less likely to be engaged across the HIV care cascade. Among Canadian women living with HIV (WLWH), we explored cascade attrition by stage and key sub-populations, and assessed correlates of attrition from 'antiretroviral (ART) adherence' to 'viral suppression'.
**Methods:** We analyzed baseline survey data from 1,425 WLWH (≥16 years; trans-inclusive) enrolled in the Canadian HIV Sexual and Reproductive Health Cohort Study (CHIWOS), Canada's largest community-based cohort of WLWH. We measured the proportion of women engaged in seven nested stages of the care cascade, via self-report: HIV-diagnosed, linked to HIV care, retained in HIV care, initiated ART, currently on ART, ART adherence (≥90%), and viral suppression (< 50 copies/mL). We examined attrition across stages overall and by age, ethnicity, housing stability, food security, illicit drug use, and violence. Among those currently on ART, multivariable logistic regression identified factors associated with not being suppressed.
**Results:** Median age was 43 (IQR: 35-50); 96% of women identified as cis-gender; 22% were Indigenous, 29% African/Caribbean/Black, and 41% Caucasian/White. Median years living with HIV was 11 (IQR: 6-17). Overall: 98% were linked to care; 96% retained; 88% initiated ART; 83% were currently on ART; 68% were adherent; and, among those on ART, 72% were virally suppressed with variation (45%-84%) by sub-population. The largest attrition occurred between 'on ART' and 'ART adherence' (-17%), with the greatest losses among women with Indigenous ancestry (-25%), current violence (-27%), and current illicit drug use (-32%). Substantial attrition also occurred between 'linked to HIV care' and 'initiated ART'(-11%), with the greatest losses occurring among women 16-29 years (-20%) and with unstable housing (-27%). Adjusted odds of not being virally suppressed were significantly higher among women who were young [aOR: 1.4 (95% CI: 1.1-1.79) per 10 years younger], food insecure [1.77 (1.03-3.05)], incarcerated in the past year [3.84 (1.56-9.45)], and currently using illicit drugs [3.25 (1.46-7.25)].
**Conclusions:** Nearly one-in-three WLWH in this Canadian cohort were lost across the HIV care cascade, with significant differences by stage, sub-population, and social inequities. Targeted interventions are needed to improve engagement across the care cascade for a diverse community of WLWH.

## TUPEB069

### INVESTIGATIVE STUDY ON MASSIVE HIV TESTING AND LINKAGE TO CARE AT HIGH BURDEN COMMUNITIES IN BENUE STATE, NIGERIA

E. Duile[1], F. Oluwasina[2], O. Gbadamosi[3], A. Towolawi[4]
*[1]AIDS Healthcare Foundation Nigeria, Prevention, Abuja, Nigeria, [2]AIDS Healthcare Foundation Nigeria, Monitoring and Evaluation, Abuja, Nigeria, [3]AIDS Healthcare Foundation Nigeria, Advocacy / Marketing, Abuja, Nigeria, [4]AIDS Health Care Foundation Nigeria, Hit Treatment, Abuja, Nigeria*
*Presenting author email: elizabeth.duile@aidshealth.org*

**Background:** HIV counseling and Testing (HCT) remains the entry point for HIV prevention, care and treatment. Despite this fact HCT uptake in Nigeria is still low. Mass HIV testing campaigns, in high burden communities with low uptake have proven to scale up HCT access and lead to successful linkage to care and treatment. Models such as PITC have showed promising results. This study demonstrates that structured HCT campaigns in communities with poor HIV treatment services, through client initiated counseling and testing leads to expansion of HCT services and consequently scale up clients enrolled to care and treatment.
**Methods:** A descriptive cross-sectional study was used by AHF Nigeria to select 15,785 individuals between 8 hours in a day from high burden communities of Agasha, Awuapila, Agu and Pevi in Guma, Buruku and KatsinaAla LGAs in Benue State who volunteered for testing. Participants were counseled, tested and received results according to the Nigeria National guidelines using an approved semi-structured questionnaire to collect socio-demographic information, knowledge and HIV risk assessment.
**Results:** Of all 15,785 participants that were screened for HIV according to the national HIV testing algorithm, 10,558 (67.5%) were males while 5,104 (32.3%) were females. 18.6% of the testers were between 0 months old-14 years of age, 43.3% were between 15 and 25 years of age, 31.4% were 25 to 49 years of age, the remaining group (6.7%) were aged 50 years and older. 73.2% got tested because they had unprotected sex, 13.1%, 9.4% and 4.3% got screened due to blood transfusion, MTCT and Injection Drug Use, respectively. 366 (2.3%) reactive cases were identified and 295 (80.6%) linked to care & treatment within 30 days. Majority (56.3) of the clients had no prior access to HIV test and were unaware of their status.
**Conclusions:** Mass testing campaigns in high burden communities without access to HIV services significantly increased knowledge of people's HIV status. Essential is that after testing active client follow-up enhances and scales up linkage to care and treatment.
It is recommended that structured HCT campaigns in communities with poor access to testing services will promote HIV treatment and contribute to the fight against AIDS.

## TUPEB070

### FEASIBILITY AND EFFECTIVENESS OF PEER NAVIGATORS TO INCREASE UPTAKE OF HIV TESTING, CARE AND TREATMENT AMONG STREET CHILDREN AND YOUTH IN ELDORET, KENYA

P. Braitstein[1], A. Kamanda[2], L. Embleton[1], E. Apondi[2], K. MacDonald[3], B. Genberg[4], M. Callaghan[1], J. Wachira[5], D. Ayuku[5]
*[1]University of Toronto, Toronto, Canada, [2]Moi Teaching and Referral Hospital, Eldoret, Kenya, [3]Indiana University, Indianapolis, United States, [4]Brown University, Providence, United States, [5]Moi University, Eldoret, Kenya*
*Presenting author email: mike.callaghan@mail.utoronto.ca*

**Background:** Preliminary research suggests a substantial epidemic of HIV among street-connected children and youth (SCY) in Eldoret, Kenya. It also suggests that very few HIV-positive SCY are engaging with HIV care or using antiretroviral therapy (ART).
We piloted and evaluated the use of Peer Navigators (PN), used successfully in other settings, to increase SCY's uptake of interventions along the HIV prevention-care continuum.
**Description:** We defined a PN as an HIV-positive person aged <25 years, with >1 year of direct experience being street-connected, current knowledge of the local SCY community, and an ability to read, write, and do arithmetic up to a Standard/Grade 4 level. One male and one female PN underwent multi-disciplinary training and subsequent mentorship and supervision. Using community outreach including daily visits to known locations SCY frequent, and accompaniment to the facility, the PN engaged 330 SCY aged <25 between May-December 2015, 28% female. Twenty-nine (9%) SCY were known positive at first contact (including 21/93, 23% of females). Another 261/301 (87%) agreed to HIV testing (including (72/72, 100% of females), of whom 27/261 (10%) tested positive (including 18/72, 25% of females). Overall, 56/330 (17%) SCY in this program were HIV-positive; 7% of males and 33% of females. Twelve are connected to care intermittently, and only 2 were on ART.
**Lessons learned:** The pilot was successful at getting SCY to test for HIV. One PN was discovered mid-way through the pilot to be HIV-negative. It was decided to maintain them in the position as having PN of mixed serostatus was thought to reduce potential stigma from having only 'known HIV-positive' PN. The very low number of positive SCY who accessed care and ART was found to be caused by HIV stigma among the SCY community, generalized stigma against SCY among healthcare providers and other HIV-positive patients, long clinic waits, a lack of safe storage for medicines, and food insecurity.
**Conclusions/Next steps:** The PN program is feasible and in some ways very effective. Next steps are to pilot creative strategies to facilitate uptake of and adherence to ART in this vulnerable and hard-to-reach population.

## TUPEB071

### TIME SINCE DIAGNOSIS TO ART INITIATION IN INDONESIA: IMPLICATIONS FOR CARE LINKAGES

A. Rahadi[1,2], L. Nevendorff[3], Y. Wirastra[4], F. Gorilla[5], A. Wardana[1]
*[1]Indonesia AIDS Coalition, Jakarta, Indonesia, [2]University of Melbourne, Centre for Health Policy, Melbourne, Australia, [3]Alma Jaya Catholic University, Centre for HIV Research, Jakarta, Indonesia, [4]Asian Network of People Who Use Drugs, Bangkok, Thailand, [5]GWL-INA, Jakarta, Indonesia*
*Presenting author email: arie.rahadi@gmail.com*

**Background:** This study examined the trend in time intervals between diagnosis to ART initiation in the periods leading up to the test-and-treat ART regime in application since 2013. We estimated the time taken to initiation by risk group, gender, and across diagnosis time.
**Methods:** Dataset was a Community Access to Treatment, Care and Support (CAT-S) study in 7 provinces of Indonesia, comprising 1,655 HIV+ surveyed participants. We used data from 1,098 on-ART participants, or 89% of the total in this category. Finite mixture models were used to differentiate distributions based on the length of time to ART initiation. These two distributions were labeled 'slow' and 'swift', respectively.
Our final model comprised risk groups, gender identity, age (and age-squared), year of initiation, whether symptoms were present at diagnosis (yes/no), and self-reported initial CD4 count.
**Results:** We included participants initiating ART from as earliest as year 2001. The 'swift' initiation group had a mean length of time to initiation of 4.78 months, whereas the comparable figure for the 'slow' initiation group was 25.37 months. People who inject drugs had the longest time to initiation in both groups. By gender, transgenders on average took an extra 3.27 months (95% CI: 2.42-4.12) to initiation compared to males. Each calendar year added less than one month to initiation time but this was highly significant for both 'slow' and 'swift' groups ($p < 0.001$). Older age was associated with more timely initiation.
**Conclusions:** Being symptomatic at diagnosis was an indication of deferred ART initiation, yet shortens time to initiation for those in the 'slow' group. People who inject drugs, younger age groups, and transgenders were at an increased risk of late ART initiation.

## TUPEB072

### INTERVENTION AND IMPACTS: TREND ANALYSIS OF RETENTION CASCADE OVER 5 YEARS IN RAJASTHAN, INDIA

M. Bamrotiya[1], R. Soni[2], V. Purohit[3], B.B. Rewari[4], S. Lamba[2]
*[1]National AIDS Control Organization, Ministry of Health and Family Welfare, New Delhi, India, [2]Rajasthan State AIDS Control Society, Jaipur, India, [3]I-TECH, New Delhi, India, [4]WHO India, New Delhi, India*
*Presenting author email: bamrotiya.manish@gmail.com*

**Background:** Rajasthan is a low prevalence state with high vulnerability for HIV, geographically largest state situated in Western India, having an estimated 103148 PLHIV. There are 23 ART Centers catering to 30,153 PLHIV, of whom 25,995 were on ART. The number of ART centers have been scaled up from 02 in 2005 to 23 in 2015. Analysis of retention cascade for 2010-11 revealed that there were significant gaps at each step.
**Description:** Review and analysis of the cascade at state level was done to identify the gaps that existed between HIV diagnosis and linkage to care, baseline CD4 testing, ART initiation and retention at 12 months. Large number of vacancies and delays in recruitment, lack of optimal coordination between the testing and treatment divisions and incomplete and poor data (for linkages, referral and drug stocks) were the key bottlenecks identified that contributed to these gaps. Programmatic and administrative interventions coupled with supportive supervision and follow up visits to all the ART centers, regular review meetings and mentoring of the staff on guidelines, data management, collection and validation were done. Capacity building at all levels for undertaking the cascade analysis, identify and fill the gaps was done. A system of sending quarterly feedback to the nodal officers and head on institutions was started to enhance the ownership of the ART centers.
**Lessons learned:** There was a rapid improvement in all the steps of the treatment cascade form 2010-11 to 2014-15.

| Year | ICTC-ART center Linkage | Baseline CD4 testing for eligibility for ART | ART initiation in eligible PLHIV | Retention at end of year |
|---|---|---|---|---|
| 2010-11 | 76% | 97% | 69% | 38% |
| 2011-12 | 81% | 98% | 68% | 39% |
| 2012-13 | 85% | 99% | 79% | 51% |
| 2013-14 | 87% | 98% | 85% | 79% |
| 2014-15 | 90% | 99% | 89% | 83% |

*[5 year performance of retention cascade]*

**Conclusions/Next steps:** Existing programmatic guidelines if implemented and enforced well can have a remarkable impact on the retention cascade. Supportive supervision and on site mentoring as well as training of the state level managers is important for resolving the administrative and programmatic issue in program implementation.

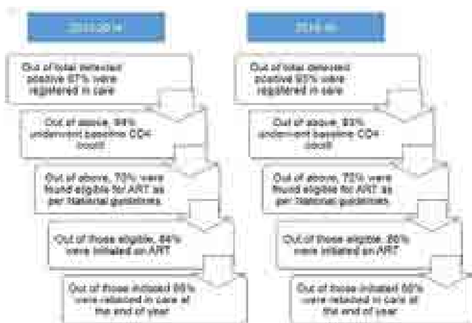
## TUPEB073

### RETENTION CASCADE IN HIV CARE SETTINGS IN INDIA: TRENDS OVER TWO YEARS

M. Bamrotiya[1], A. Sinha[1], B.B. Rewari[2], M. Mhetre[1], A.S. Rathore[1], V. Purohit[3], S. Kumar[1], R. Rana[1]
*[1]National AIDS Control Organization, Ministry of Health and Family Welfare, New Delhi, India, [2]WHO India, New Delhi, India, [3]I-TECH, New Delhi, India*
*Presenting author email: drmmnaco@gmail.com*

**Background:** Approximately 0.2 million newly detected HIV positive person register every year in National ART programme at 520 ART across the country. The National programme aims in providing universal access to comprehensive care package and improvement in quality of life of PLHIV through a network of ART facilities and Care and support centers. Retention in care is a vital component of programme to achieve and sustain high level of viral suppression. Cascade model for measuring sequential retention at each stage is a useful way of monitoring trends and planning need based interventions.
**Description:** The retention cascade refers to the flow of patients from diagnosis of HIV to screening for ART eligibility, ART initiation for eligible patient and retention of patients who start ART. It outlines the proportion of individuals living with HIV who

are engaged at each stage of cascade. It provides information that is very important for programme to constitute measures to plug the losses at each steps. It also gives an indirect measure of quality of services provided at service delivery site.
**Lessons learned:** As per data available from Monthly reports of HIV care settings, it was observed that in year 2013-14, out of total new HIV +ve diagnosed in 2013-14 and 2014-15 following is the scenario:



[National level retention cascade-comparing two consecutive years]

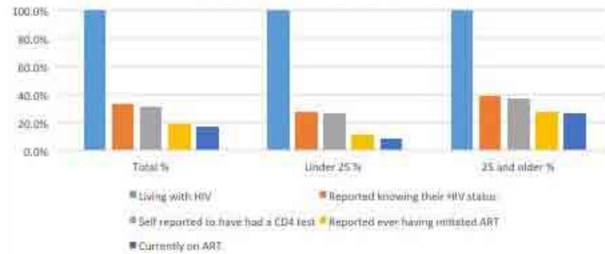
The improving trend has been observed in critical steps of linkages from testing to treatment sites and initiation of ART, also programme continues to maintain high level of retention. This is mainly due to regular facility level cascade analysis, supportive supervision and mentoring by regional coordinators and administrative interventions. However continuous focus is needed to sustain and improve performance to achieve target of universal coverage.
**Conclusions/Next steps:** Close monitoring of data using cascade based approach can be an effective way of improving programme performance. Need based interventions should be planned to plug the leaky cascade.

## TUPEB074

### THE HIV TREATMENT CASCADE AMONG MEN WHO HAVE SEX WITH MEN IN COTE D'IVOIRE: CHARACTERIZING THE ABSOLUTE AND RELATIVE UNMET TREATMENT NEEDS

D. Diouf[1], R. Ezouatchi[2], F. Drame[3], M. Thiam[1], A. Kouamé[4], C. Lyons[5], S. Ketende[5], B. Liestman[6], A. Bamba[1], S. Baral[5]
*[1]Enda Sante, Dakar, Senegal, [2]Gaston Berger University, Abidjan, Cote D'Ivoire, [3]Gaston Berger University, Saint-Louis, Senegal, [4]Programme National de Lutte contre le Sida, Ministère de la Santé et de la Lutte contre le Sida, Abidjan, Cote D'Ivoire, [5]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States*
*Presenting author email: dioufda@endatiersmonde.org*

**Background:** Men who have sex with men (MSM) are disproportionately affected by HIV compared to other men—globally. In the West African nation of Cote D'Ivoire (CDI), MSM have consistently been shown to have high prevalence of HIV in small studies with separate qualitative data suggesting significant structural barriers to the uptake of anti-retroviral therapy (ART). The objectives of these analyses are to characterize the determinants of engagement in the HIV treatment cascade among MSM in CDI to inform the scale and implementation of ART programs.
**Methods:** From 03/2015-10/2015, 1101 MSM were sampled in 4 cities Abidjan(n=351), Bouake (n=350), Gagnoa (n=150), Yamoussoukro (n=250), administered a structured-survey instrument, and completed HIV testing according to national guidelines. EpiData was used for data management, and Stata 14 was used for data cleaning and analysis including fisher's exact test for comparison of proportions by age and city.
**Results:** The HIV prevalence varied significantly ($p < 0.01$) by city with the highest prevalence in Abidjan (29.3%), then Yamoussoukro (10%), Gagnoa (4.7%), and then Bouake (3.5%) for an overall HIV prevalence of 12.9% (Figure 1). Overall, 32.8% (n=45/137) of those living with HIV reported knowing their status, of whom 95.6% had a CD4 count (n=43/45), 57.8% had ever initiated ART (n=26/45), of whom 88.5% (n=23/26) reported current ART use with no viral load (VL) data available. However, those >25 years were significantly more likely to have ever initiated ART and currently be on ART ($p < 0.05$).
**Conclusions:** These data demonstrate significant losses in the HIV treatment cascade especially where MSM have limited awareness of their HIV status. Moreover, this may represent an overestimation of ultimate viral suppression given known ART adherence challenges and the lack of VL data. Taken together, these data suggest the need for significant scale-up of linkage and retention to ART programs for MSM in CDI implemented together with stigma mitigation programs to optimize the provision and uptake of these services.



*[Figure 1. HIV cascade amongst MSM by age]*

## TUPEB075

### UPTAKE OF AND EARLY ADHERENCE TO LIFELONG ART (OPTION B+) AND ASSOCIATED FACTORS AMONG PREGNANT WOMEN IN UGANDA

A.D. Mukose[1,2], F. Makumbi[1], H. Bastiaens[3], E. Buregyeya[4], R. Naigino[5], J.-P. Van Geertruyden[2], R. Wanyenze[4]
*[1]Makerere University School of Public Health, Epidemiology and Biostatistics, Kampala, Uganda, [2]University of Antwerp, Epidemiology and Social Medicine, Antwerp, Belgium, [3]University of Antwerp, Primary and Interdisciplinary Care, Antwerp, Belgium, [4]Makerere University School of Public Health, Disease Control and Environmental Health, Kampala, Uganda, [5]Makerere University School of Public Health, Global Fund-PMTCT Study, Kampala, Uganda*
*Presenting author email: amukose@musph.ac.ug*

**Background:** Use of antiretroviral treatment (ART) by HIV+ pregnant women has significantly reduced mother-to-child transmission of HIV. However, uptake of and adherence to lifelong ART, and associated factors among pregnant women have not been fully evaluated in many Ugandan settings.
**Methods:** A cross-sectional study was conducted in six health facilities offering ART in Masaka, Mityana, and Luwero districts in Uganda. We analyzed data for 385 women who came for their first post enrollment visit during antenatal and were part of 507 women enrolled into a prospective cohort within four weeks of ART initiation. Uptake was defined as the proportion of women that had swallowed ARVs, while adherence was classified as good if women reported swallowing at least 95% of ART doses in the 30-days prior to the interview or poor adherence if swallowed less than 95%. Independent factors associated with adherence were obtained through multivariable logistic regression model using STATA version 12.
**Results:** Half (50.7%) of women were young (16-24 years). 96.9% (373/385) were prescribed ART with Mityana Hospital at 100% (170/170) followed by Luwero HCIV and Masaka RRH at 98.8% (79/80) and 91.9% (124/135) respectively prior to the first follow-up visit. Uptake of ART was nearly universal (362/373, 97.1%), and early adherence was suboptimal (78.4%). Being immediately ready to start ART (adj. PRR= 3.2; 95% CI: 1.16-8.87) and disclosure of being on ART (adj. PRR= 1.22; 95% CI: 1.04-1.44) were associated with higher prevalence of good adherence. The prevalence of good ART adherence was higher at Mityana Hospital (adj. PRR= 1.47; 95% CI: 1.19 - 1.81) and Masaka RRH (adj. PRR=1.35; 95% CI: 1.09-1.67) relative to Luwero HCIV.
**Conclusions:** Uptake of lifelong ART was nearly universal but adherence in the first 2 months was sub-optimal. Efforts to enhance education and support HIV status disclosure are required to maximize the benefits of ART for HIV positive pregnant women.

## TUPEB076

### INNOVATIVE MODELS FOR MONITORING LINKAGE AND ADHERENCE TO ART AMONG KEY POPULATIONS TO ACHIEVE THE 90-90-90 STRATEGY IN MARPI ART CLINIC

G. Katushabe[1], J.R. Lule[1], R. Kindomunda[2], P. Kyambadde[3], B. Abio[1], J. Katende[1]
*[1]Most At Risk Population Intiative (MARPI), ART Clinic, Kampala, Uganda, [2]UNFPA, Kampala, Uganda, [3]STD/MOH, STD/AIDS Control Program, Kampala, Uganda*
*Presenting author email: sanlulejr@gmail.com*

**Background:** Majority of KPs in Uganda access services within their hotspots including HCT, thus requiring referrals for linkage to care. Once linked the next challenge is retention in care accompanied by adherence to medications for populations that face a lot of stigma and discrimination and often live hidden and sometimes mobile lives. Retention in care and adherence to medications has remained a very big challenge for many providers of ART care to sex workers and many get lost to follow-up given the test and treat policy for SW once diagnosed with HIV. This is also not helped by hostile legal environment. We developed a model of care involving KPs in the delivery of ART care to improve retention in care and adherence to ART for KPs attending the MARPI clinic.

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

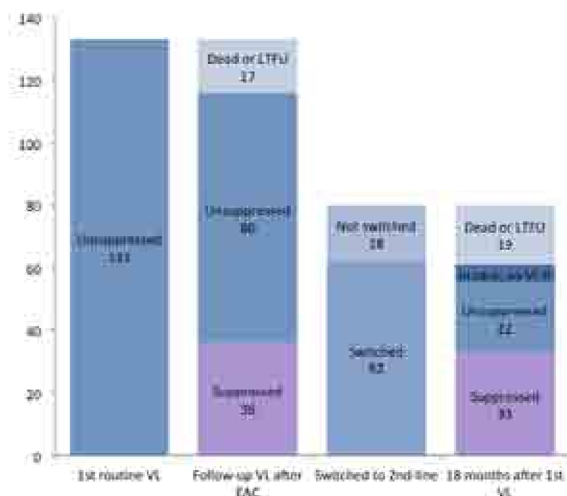
**Methods:** KPs diagnosed with HIV are linked to the MARPI clinic by KP peers and once enrolled onto ART are followed by K-peers at the hotspots for adherence to medication, honoring clinic appointments and following and finding those that fail to return to the clinic either by refusal or after moving to another hotspot. KPs with HIV are initiated on ART using standard procedures by a health team that includes the hotspots KP peer as the facility-community liaison.
**Results:** From April 2013 to the end of 2015, 750 KPs were enrolled in MARPI ART clinic (89% were sex workers and 11% LGBTI) and have been in care for at least 6 months. Of these 83% were initiated on ART and by the end of 2015, 14% (106 KPs) had not returned to the clinic for 3 or more months. Of those attending 83 (15%) were in another health unit. Of those in the clinic 16 (3%) had died). Of the remaining 445, after 6 months on ART, 79% had undetectable viral load.
**Conclusions:** Including KPs as part of the health care team for KPs on ART achieves a reasonable degree of viral suppression by improving adherence and clinic attendance. ART Care Models for KPs on ART should include KPs on the health team if ART care among KPs is to achieve the 90-90-90 target.

## TUPEB077

### LEAKS IN THE HIV TREATMENT FAILURE CASCADE: THE REALITY IN RURAL LESOTHO

I. Ringera[1], D. Puga[2], M. Motlatsi[1], C. Fritz[3], B. Cerutti[4], T.I. Lejone[1], T. Klimkait[5], N.D. Labhardt[6]
*[1]SolidarMed, Swiss Organization for Health in Africa, Butha-Buthe, Lesotho, [2]Partners in Health, Maseru, Lesotho, [3]SolidarMed, Swiss Organization for Health in Africa, Maseru, Lesotho, [4]University of Geneva, Medical Faculty, Geneva, Switzerland, [5]Department of Biomedicine - Haus Petersplatz, Molecular Virology, Basel, Switzerland, [6]Swiss Tropical and Public Health Institute, Medical Services and Diagnostics, Basel, Switzerland*
*Presenting author email: i.ringera@solidarmed.ch*

**Background:** Based on WHO recommendations many resource-limited settings have started rolling out routine viral load (VL) monitoring. In a prospective study on comorbidity and virologic outcomes among patients on ART in rural Lesotho (CART-1, clinicaltrials-ID: NCT02126696) we followed clinical and virological outcomes of patients who had unsuppressed viremia at their first-time VL.
**Methods:** Adult patients ($^{\geq}$16 years) on first-line ART for $^{\geq}$6 months at 10 facilities of two districts in Lesotho received a first routine VL. As recommended by the WHO guidelines, patients with unsuppressed VL received enhanced adherence counselling (EAC) and follow-up VL after 3 months. Patients with sustained unsuppressed VL, defined as both VL ≥100copies/mL, were considered eligible for switch to second-line ART. Clinical and virological outcomes were assessed 18 months after the first unsuppressed VL.
**Results:** The treatment failure cascade of 133 individuals on first-line ART (65.9% female) with VL≥100copies/mL is shown in figure 1.



*[Figure 1: The treatment failure cascade in 133 adult patients on first-line ART with a first-time unsuppressed viral load (VL)]*

A considerable loss in the effectiveness of the roll-out of VL testing could be observed at all steps: Of 80 patients with sustained unsuppressed VL 33 (41%) were retained in care with documented viral suppression at 18 months. Among the 62 switched to second-line 33 (53%) fully resuppressed HIV. Age, gender, household wealth, self-reported adherence, distance to facility, time on ART, educational level were found not to be associated with successful viral resuppression.
**Conclusions:** Attrition from care and incorrect management of patients with unsuppressed VL (i.e. failure to switch to second-line despite sustained unsuppressed VL) were the main drivers decreasing effectiveness of VL-monitoring in this setting. In addition, among those who switched to second-line only 53% had documented viral resuppression 18 months after first indication of treatment failure, indicating that persistently poor adherence may be the main parameter in the treatment failure cascade.

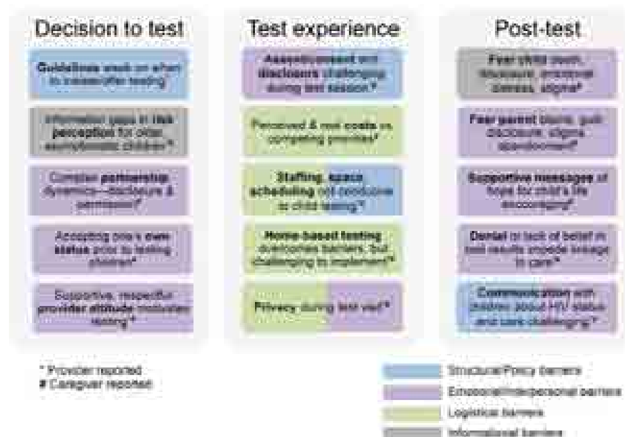
# DIAGNOSIS OF HIV DISEASE IN INFANTS, CHILDREN, AND ADOLESCENTS

## TUPEB078

### HIV TESTING FOR OLDER CHILDREN: A MIXED-METHODS STUDY EXAMINING CHALLENGES IN DECISION TO TEST, TESTING PROCESS, AND COPING POST-TESTING

A.D. Wagner[1], G. O'Malley[1], O. Firdawsi[1], C. Mugo[2], I. Njuguna[1,2], E. Maleche-Obimbo[2], I. Inwani[3], D. Wamalwa[2], G. John-Stewart[1], J. Slyker[1]
*[1]University of Washington, Global Health, Seattle, United States, [2]University of Nairobi, Pediatrics & Child Health, Nairobi, Kenya, [3]Kenyatta National Hospital, Nairobi, Kenya*
*Presenting author email: anjuliw@uw.edu*

**Background:** Prompt testing and treatment of HIV-infected children is critical; yet, programs that routinely test older children prior to symptomatic disease are largely absent. Testing children of HIV-infected adults in care presents an opportunity for efficient case detection prior to symptomatic illness; understanding the challenges associated with this testing model can provide insights to increase uptake of testing.
**Methods:** Three focus group discussions with health care workers and 18 semi-structured, in-depth interviews with HIV-infected adults in care with children of unknown status were conducted at Kenyatta National Hospital. Structured questionnaires were conducted with 116 HIV-infected adults in care with children of unknown HIV status, and quantitative data were used to generalize and validate the qualitative findings.
**Results:** Qualitative data revealed challenges during three periods of the pediatric HIV testing process: concerns about the decision-making process to test, the test visit itself, and coping during the post-test period. The greatest challenges from both qualitative and quantitative sources were inaccurate information about the likelihood of child infection and prognosis (most parents assumed either that older children could not be infected or were inevitably infected), challenges with permission and disclosure with partners, experiences with discouraging provider attitudes, lack of clear pediatric testing guidelines around consent/assent and disclosure to children, insufficient staff and inappropriate space for children, concerns about privacy, and real and perceived costs of testing and treatment.
**Conclusions:** Interventions are needed to address client, provider, and clinic-level challenges to pediatric HIV testing. Assisted disclosure services, small financial incentives, peer support groups, in-service provider training, and weekend and school holiday clinic dates merit evaluation to address challenges to pediatric testing.



*[Challenges to pediatric HIV testing]*

## TUPEB079

### WHO HIV TESTING ALGORITHM FAILS TO IDENTIFY SUBSTANTIAL PROPORTION OF INFANTS WITH HIV INFECTION

A.D. Wagner[1], I. Njuguna[1,2], R. Asiko Andere[3], L. Cranmer[4], H. Okinyi[2], S. Benki-Nugent[1], E. Maleche-Obimbo[2], D. Wamalwa[2], G. John-Stewart[1]
*[1]University of Washington, Global Health, Seattle, United States, [2]University of Nairobi, Pediatrics & Child Health, Nairobi, Kenya, [3]Kenyatta National Hospital, Nairobi, Kenya, [4]Emory University, Atlanta, United States*
*Presenting author email: anjuliw@uw.edu*

**Background:** The WHO HIV testing algorithm for infants at sick care visits involves HIV serologic testing followed by virologic testing if seropositive. Additionally, in PMTCT programs, HIV-exposed infant testing algorithms include virologic testing at 6 weeks, and serologic testing at 9 and 18 months. PCR testing is conducted on infants with positive HIV serology while seronegative infants receive repeat serotesting at future visits.
**Methods:** Within a clinical trial (NCT02063880) conducted among critically ill, hospitalized children in 4 Kenyan hospitals, serologic and virologic tests on all HIV-exposed infants ≤9 months were performed. Maternal and infant serologic tests (using Determine® or KHB® for first test and Unigold® or First response® for second test per Kenyan guidelines) were performed in tandem. Dry blood spots were collected and tested using HIV DNA PCR irrespective of serological test results to determine the proportion of infant infections missed by the WHO algorithm.
**Results:** Among 142 HIV-exposed infants ≤9 months with both serologic and PCR testing, 44 (31%) were PCR positive. Among 50 seronegative infants 12 (24%) were PCR positive; among 82 seropositive infants 29 (35%) were PCR positive; among 10 serology indeterminate infants 3 (30%) were PCR positive. The research algorithm, which included PCR testing of seronegative infants, identified 38% more infant infections, compared to the WHO algorithm (44 vs 32 infections, respectively). Among the 12 serology negative, PCR positive infants, 7 (58%) were missed by PMTCT programs because their mothers reported testing HIV negative during pregnancy, likely representing acute infections during latepregnancy and postpartum; 2 (17%) infants of known HIV-infected mothers had tested negative earlier during infancy, likely representing breastfeeding transmissions; 2 (17%) infants were not previously tested despite known maternal HIV status; and 1 infant's mother was not tested for HIV in pregnancy.
**Conclusions:** The current WHO HIV testing algorithm for sick infants using serology for screening did not detect a substantial number of infants with HIV infections detected by PCR. Virologic testing of HIV-exposed infants presenting for sick visits, regardless of their serologic status, may be warranted to improve early detection and treatment of HIV.

## TUPEB080

### THEY ARE LIKELY TO BE THERE: FAMILY TESTING APPROACH TO FACILITATE ACHIEVEMENT OF 90-90-90 STRATEGY IN KENYA

N. Okoko[1], P. Oyaro[1], E. Akama[1], M. Mburu[1], F. Otieno[1], C. Blat[2], H. Muttahi[3], L. Abuogi[4], E.A. Bukusi[5], C.R. Cohen[2], J.L. Kulzer[2]
*[1]Kenya Medical Research Institute (KEMRI), Center for Microbiology Research, Kisumu, Kenya, [2]University of California San Francisco, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV&TB, Nairobi, Kenya, [4]University of Colorado, Department of Pediatrics, Denver, United States, [5]Kenya Medical Research Institute (KEMRI), Center of Microbiology Research, Kisumu, Kenya*
*Presenting author email: awuornicollate@gmail.com*

**Background:** In Kenya, less than half of all children 18 months to 14 years old with a HIV-positive parent have ever been tested for HIV. Strategies to identify and test children at increased risk for HIV are critical. This study examined the impact of a family-centered approach to reach children (0-14 years) with HIV testing.
**Methods:** We conducted a retrospective review of clinical records among a convenience sample of 60 high-volume clinics in Kisumu, Homabay and Migori counties. We reviewed the records of adult index patients who were enrolled in family-centered HIV care between May-July 2015 and followed family outcomes through October 2015. Family member testing status, results, enrollment in care and ART initiation for those positive were abstracted; chi-square test was used to compare the positivity proportion differences among children to
1) prior studies[1,2] that used the family approach in the same region and
2) outpatient and inpatient testing data performed in the same region from July-September 2015.
**Results:** Review of 1,937 adult patient charts led to the identification of 3,033 eligible children for testing. There were 1,869 (62%) children tested, among which 100 (5.4%) were HIV-positive, of whom 87 (87%) were successfully linked to care and 73 (84%) had initiated ART by October 2015. Compared to prior evaluations, a declining trend in HIV positivity among children was found with the family-centered approach: the proportion of children testing positive went from 18% in 2009 to 7.4% in 2012 to 5.4% in 2015 (p< 0.001). Positive proportions among children reached through the family approach were higher than inpatient 24/1,636 (1.5%; p< 0.001) and outpatient 309/46,002 (< 1%; p< 0.001) testing proportions.
**Conclusions:** The family approach leads to high proportion of HIV positive children identified, linked to care, and initiated on ART. Although HIV positive proportions among children were lower than observed in previous family approach studies and appear to be declining, it continues to have a higher yield than program-wide inpatient and outpatient testing. The family-testing approach offers an important entry point for identification of children at risk of HIV and the opportunity for targeted follow-up through the HIV care cascade.

### EVALUATION OF HIV TESTING AND ANTIRETROVIRAL THERAPY INITIATION AT BIRTH: PRELIMINARY RESULTS FROM A PRIMARY AND SECONDARY CARE SETTING IN JOHANNESBURG, SOUTH AFRICA

N. Mvundla[1], N. Chandiwana[1], L. Fairlie[1], N. Dumakude[1], S. Mdada[1], E. Mabanga[2], T. Ncube[2], N. Madonsela[2]
*[1]Wits Reproductive Health and HIV Institute(WRHI), University of Witwatersrand, Johannesburg, South Africa, [2]Department of Health, Johannesburg, South Africa*
*Presenting author email: nmvundla@wrhi.ac.za*

**Background:** In June 2015, birth HIV testing for all HIV-exposed infants was included in the South African National Consolidated Guidelines for the first time. We describe the preliminary impact of very early infant diagnosis on combined antiretroviral therapy (cART) initiation and the feasibility of implementation in a primary (PHC) and secondary care setting.
**Methods:** A retrospective review of all birth HIV PCRs was conducted at the labour wards of two large health care facilities in Johannesburg from 1st June to 31st December, 2015. Infant birth HIV status was determined by heel prick HIV dried blood samples at the referring National Health Laboratory Service (NHLS), with results available within 48 hours. All mothers were counselled regarding HIV testing and results. At the 3-day postnatal visit, infants found to be HIV-positive were initiated on ART either at the facility's HIV clinic or referred to the nearest initiating facility.
**Results:** Of 2170 infants delivered at the PHC facility, 27% (576/2170) were HIV-exposed and tested at birth. Of these infants, 7(1.2%) had a positive HIV-DNA PCR. The HIV sero-prevalence rate in this maternal population is around 25%, a proxy for the expected number of HIV-exposed infants requiring birth testing. Of these, 6 infants were initiated on cART, with a median time to initiation of 7 days. 1 infant was lost to follow-up despite vigorous tracing. Of 1701 infants delivered at the secondary facility, 18% (318/1701) were tested for HIV at birth and 2(0.6%) were found to be HIV-positive. All infants at this facility are down-referred to a PHC facility before birth HIV DNA PCR results are available; therefore initiation of these infants could not be confirmed and could not be traced.
**Conclusions:** Our preliminary results suggest that HIV birth testing at PHC level is both feasible and effective at identifying HIV-exposed infants early and initiating them on cART. However, gaps in the referral system at secondary level hindered early initiation of HIV-positive infants, ultimately undermining the goal of the new consolidated guidelines of birth testing. Further studies and consideration from policy makers are required.

## TUPEB082

### THE VALUE OF A POSITIVE ANTIBODY TEST AT 9, 12, AND 15 MONTHS IN HIV EXPOSED INFANTS ENROLLED AT THE BAYLOR CENTER OF EXCELLENCE (COE) IN MWANZA, TANZANIA

J. Gwimile[1], S. Shea[2], E. Batungi[1], B. Mgiriwa[1], P. Mrema[1], E. Kateng'anyi[1], M. Chimwanda[1], M. Minde[1], L. Mwita[1,2]
*[1]Baylor College of Medicine Children's Foundation Tanzania, Mwanza, Tanzania, United Republic of, [2]Baylor International Pediatric AIDS Initiative, Pediatrics, Mwanza, Tanzania, United Republic of*
*Presenting author email: sshea@bcm.edu*

**Background:** Tanzania national guidelines recommend different HIV testing algorithms based on age: 0-9 months DNA/PCR is the initial test and at 9-18 months rapid antibody tests are performed first then DNA/PCR if the rapid test is positive. At the COE, DNA/PCR is done at 4-6 weeks or at the initial visit for children under 9 months at enrollment who have not previously been tested, and rapid tests at 9, 12, 15 and 18 months. This study compares the results of rapid tests and DNA/PCR at 9, 12 and 15 months.
**Methods:** This is a cross-sectional descriptive study looking at exposed infants enrolled in care from January 2014 to December 2014. Patient test results were ob-

tained from reviewing the patients' electronic medical records. Data analysis was done by SPSS 20.

**Results:** 146 infants (72 males, 74 females) were enrolled. 88 were <6 months, 27 were 6-12 months and 31 were 12-18 months. Modes of feeding: 57 infants were exclusively breastfed, 53 were mixed feeding, 3 were formula fed and 33 did not have their feeding status documented. 64.4% of mothers were on ART and 58.3% infants received NVP for 6 weeks.

| Age | Rapid Test Done | Rapid Test (+) | Rapid Test (-) | DNA PCR Done | DNA PCR (+) | DNA PCR (-) |
|---|---|---|---|---|---|---|
| < 6 months | | | | 108 | 17 | 91 |
| 9 months | 99 | 44 | 45 | 41 | 6 (14%) | 35 |
| 12 months | 37 | 13 | 24 | 11 | 8 (72%) | 3 |
| 15 months | 23 | 10 | 13 | 8 | 7 (88%) | 1 |

*[Rapid test and DNA/PCR results]*

Infants with positive DNA/PCR were more likely to be enrolled in care late, be mixed feeding, have mothers who were not on ART, and not to have received NVP prophylaxis.

**Conclusions:** Rapid antibody tests done at 12 and 15 months were more reflective of a child's true status than at 9 months. With frequent shortages of DNA/PCR test kits and a poor correlation between rapid antibody tests and DNA/PCR at 9 months, delaying surveillance testing using rapid antibody tests until 12 months may improve the clinical utility of the test as well as provide a more cost effect approach to early infant diagnosis.

*Presenting author email: ckiyaga@gmail.com*

**Background:** Early infant diagnosis (EID) testing to identify HIV-infected children remains the gateway for life-saving pediatric anti-retroviral treatment (ART). Despite notable progress in elimination of mother-to-child transmission (EMTCT) programming, EID testing coverage of the annual UNAIDS estimated 1.3 million HIV-exposed infants in sub-Saharan Africa remains inadequate; less than 50% received an EID HIV test within the first two months of life in 2014, and only 30% of HIV-infected infants are on ART. EID programs continue to face unique challenges, including where to find the children who are in need of this test. Current WHO guidelines suggest the expansion of testing and screening outside of EMTCT, but an assessment of prevalence and yield at various entry points has not been explored previously. Our study assessed the HIV infection prevalence of children receiving care at various service entry points in health facilities in Uganda.

**Methods:** We consecutively enrolled and tested infants 24 months of age and below at four major hospitals across Uganda. Six hundred children across four hospitals were included for each of the six major infant/child service entry points of the facilities: EMTCT, immunization, inpatient, nutrition, outpatient, and outreach. Each infant received a virological EID test to determine infection status.

**Results:** A total of 117 infants were HIV-positive for an overall prevalence of 3.25%. The traditional EID entry point, EMTCT, had a prevalence of 3.84%, representing 19.6% of the HIV-infected infants identified. Fifty percent of the 117 identified HIV-positive infants were found in the nutrition wards, which had a prevalence of 9.83% (p< 0.001 compared to EMTCT). Inpatient wards had a prevalence of 3.50% and yielded 17.9% of the infected infants identified. Immunization wards and outreach had the prevalence at less than 0.35%, and yielded 0.8% and 1.7% of the infected infants identified, respectively.

**Conclusions:** More effective identification of HIV-infected infants is critical to improve case-finding and initiate infants on life-saving ART. While EID testing should remain at EMTCT, strengthened, testing approaches should consider high HIV prevalence rates at nutrition and inpatient wards, which indicate that universal virological testing should be prioritized routinely at those entry points.

# PHARMACOKINETICS / PHARMACODYNAMICS / PHARMACOGENOMICS IN INFANTS, CHILDREN, AND ADOLESCENTS

## TUPEB084

### IMPACT OF HIV INFECTION ON THE PHARMACOKINETICS OF FOUR FIRST-LINE ANTITUBERCULOSIS DRUGS IN CHILDREN WITH TUBERCULOSIS IN GHANA

A. Kwara[1,2], H. Yang[3], A. Enimil[4,5], A. Sarfo[4], D. Ansong[4,5], F. Gillani[1,2], A. Dompreh[6], A. Ortsin[4], T. Opoku[4], D. Bosumtwe[4], L. Wiesner[7], J. Norman[7], C. Peloquin[8], S. Antwi[4,5]

*[1]Alpert Medical School of Brown University, Medicine, Providence, United States, [2]Miriam Hospital, Medicine, Providence, United States, [3]University of Rochester School of Medicine and Dentistry, Department of Biostatistics and Computational Biology, Rochester, United States, [4]Komfo Anokye Teaching Hospital, Directorate of Child Health, Kumasi, Ghana, [5]Kwame Nkrumah University of Science and Technology, Department of Child Health, Kumasi, Ghana, [6]Komfo Anokye Teaching Hospital, Kumasi, Ghana, [7]University of Cape Town, Department of Medicine, Cape Town, South Africa, [8]University of Florida, College of Pharmacy and Emerging Pathogens Institute, Gainesville, United States*

*Presenting author email: awewura_kwara@brown.edu*

**Background:** HIV/TB co-infected children have a higher risk of dying from TB than children with TB alone during antituberculosis (anti-TB) therapy. The poor outcome may in part be due to lower anti-TB drugs exposure in the co-infected children. This study compared the pharmacokinetics of four first-line anti-TB drugs in children with TB/HIV coinfection to those with TB alone.

**Methods:** Children with TB with or without HIV coinfection on first-line anti-TB therapy for at least 4 weeks had blood samples collected at pre-dose, 1, 2, 4, and 8 hours post-dose. Drug concentrations were determined by validated liquid chromatography mass spectrometry methods and pharmacokinetic parameters calculated using noncompartmental analysis. Differences in PK parameters for each drug between children with TB alone and those with HIV/TB coinfection were compared.

**Results:** Of the 113 study participants, 59 (52.2%) had HIV coinfection, 63 (55.8%) were male, the median (IQR) age was 5.0 (2.2 - 8.5) years old, 23 (20.3%) were aged < 2 years old and 53 (46.9%) aged < 5 years old. The baseline characteristics and drug dosages for the two groups were similar except HIV/TB co-infected patients were more likely to have a lower weight-for-age and height-for age z-scores ($P < 0.05$). The median plasma area under the concentration-time curve from 0 to 8 hours for isoniazid in the children with TB/HIV coinfection and TB alone were (18.4 vs. 21.2 µg*hr/mL; $P$=0.231), rifampin were (24.9 vs. 30.5 µg*hr/mL; $P$ = 0.030), pyrazinamide (126.5 vs. 151.0 µg*hr/mL; $P$ = 0.034) and ethambutol (4.8 vs. 7.6 µg*hr/mL; $P$ = 0.0003), respectively. The median weight-normalized apparent oral clearance for isoniazid in the children with TB/HIV coinfection and TB were (0.50 vs. 0.44 L/hr/kg; $P$=0.405), rifampin were (0.53 vs. 0.45 L/hr/kg; $P$=0.044), pyrazinamide (0.12 vs. 0.10 L/hr/kg; $P$=0.010) and ethambutol (2.95 vs. 1.96 L/hr/kg; $P$=0.0009), respectively.

**Conclusions:** HIV coinfection is associated with a higher clearance and a lower plasma exposure of rifampin, pyrazinamide and ethambutol in Ghanaian children with TB. Whether higher drug dosages may improve drugs pharmacokinetics and treatment outcomes in co-infected children need to be investigated.

## TUPEB085

### GROWTH RESPONSE TO ANTIRETROVIRAL THERAPY (ART) INITIATION AMONG HIV-INFECTED CHILDREN IN CARE IN WESTERN KENYA

S. Olwambula Ayaya

*Moi University, Child Health and Pediatrics, Eldoret, Kenya*

*Presenting author email: ayaya.samuelaluanga@gmail.com*

**Background:** In children HIV infection may cause growth failure which can be a proxy for treatment failure and disease progression. We investigated the rapid growth response to initiation of antiretroviral therapy shown by studies among HIV-infected children and associated factors.

**Methods:** We conducted a retrospective of analysis of prospectively collected data in the database on HIV infected ART-naïve children aged below 13 years attending the AMPATH pediatric clinics between 2005 -2009.A two-piece structural causal model was used to characterize the effect of ART initiation on anthropometric measures. Models were fitted separately by age (<2 vs >2 years) and CDC class at enrollment.

**Results:** Of 4147 participants included, 2208 (53%) were ever on ART and 3362 (81%) were aged below 2 years at enrollment. Average baseline weight-for age (WAZ), height-for-age (HAZ) and weight-for-height (WHZ) z scores among those <2 years were -1.97 ±1.83, -1.69 ± 1.60 and -0.57 ± 1.76 respectively. Those aged <2 years had dramatic improvement in WAZ scores during the first year stabilizing at

-1; those aged >2 years, had rapid improvement in WAZ scores during the first 6 months stabilizing at -1.5. Within CDC classes, benefits of ART on WAZ were realized within the first year.
**Conclusions:** ART initiation in children leads to growth recovery which plateaus below normal. Degree of recovery is more pronounced among younger children.

## CLINICAL TRIALS AND ANTIRETROVIRAL THERAPY IN INFANTS, CHILDREN, AND ADOLESCENTS

### TUPEB086

### STRUCTURED ANTIRETROVIRAL TREATMENT INTERRUPTIONS IN VERTICALLY HIV-1 INFECTED CHILDREN WITH COMPLETE PRO-VIRAL DNA PCR REVERSIONS IN NAMIBIA, FOLLOWING DURABLE VIRAL SUPPRESSION, LED TO RAPID REBOUND VIREMIAS AND SIGNIFICANT IMMUNOLOGIC DESTRUCTION

T. Mekonen[1], R. Mulang[2], H. Nghiimbwasha[2], S. Mpariwa[2], J. Kamangu[2], N. Odon[2], J. Hango[2], N. Hamunime[1]
*[1]Ministry of Health and Social Services of Namibia, Sub-division HIV and STI Control, Windhoek, Namibia, [2]Ministry of Health and Social Services, Ohangwena Regional Health Directorate, Eenhana, Namibia*
*Presenting author email: tadeteferi@gmail.com*

**Background:** Early anti-retroviral therapy (ART), in vertically HIV-1 infected children, can lead to reversion of pro-viral HIV DNA PCR test to negative. This may pose clinical dilemmas to healthcare workers (HCWs) leading to misclassification of HIV status. We followed five children who had DNA PCR and antibody reversions, in whom primary healthcare providers erroneously ruled-out HIV infection.
**Description:** Review of the medical records revealed that three of them were females. Four were tested positive with single HIV DNA PCR within six months of age and one at 10 months. Four started ART before the age of 1 year and one at 21 months. Viral loads (VLs) were undetectable in all children by 21-35 months of treatment. After about 2 years of ART, HIV antibody and DNA PCR tests turned negative in all cases. Undetectable VLs in these children prompted HCWs to repeat DNA PCR and antibody tests, both of which returned negative. HCWs then mistakenly informed the parents that their children were HIV un-infected. To clear the clinical dilemma, we instituted structured treatment interruption with close follow up and VL monitoring.
**Lessons learned:** Following structured treatment interruption for a median duration of 6 weeks, we detected high level rebound viremias in all children in the range of 135,409 and 8,400,337 RNA copies/ml. CD4 loss of up to 15% was observed within 3 months from the points of ART interruption. Care givers received counseling and the children were re-started and maintained on ART. All children fully suppressed the virus again within 6 to 9 months of re-treatment and maintained suppression for 18 to 24 months now.
**Conclusions/Next steps:** These cases illustrated pro-viral HIV DNA reversions in vertically HIV-1 infected children, on ART, following durable viral suppression. The rapid post-treatment interruption viral rebound illustrated that prolonged viral remission is unlikely unless very early treatment is started. Treatment interruptions lead to significant immunologic destructions and shall not be implemented in such children in resource constrained settings. Reversion phenomena may become commoner with increasing access to early ART in vertically infected children in Africa. HCWs shall be made aware of such phenomena and children should receive timely HIV disclosure.

### TUPEB087

### TARGETING GUT MICROBIOTA OF VERTICALLY HIV-INFECTED CHILDREN AND ADOLESCENTS: A PILOT STUDY

T. Sainz[1], N. Jiménez-Hernández[2], J. Vazquez-Castellanos[2], M.J. Mellado[3], S. Guillén[4], J.T. Ramos[5], S. Serrano-Villar[6], S. Moreno[7], M.J. Gosalbes[2], M.L. Navarro[8], Spanish National Network for HIV-infected Children and Adolescents, CoRISpeS
*[1]Hospital Universitario La Paz e IdiPAZ, Pediatrics, Madrid, Spain, [2]FISABIO, Valencia, Spain, [3]Hospital Universitario La Paz e IdiPAZ, Madrid, Spain, [4]Hospital de Getafe, Madrid, Spain, [5]Hospital Clinico San Carlos, Madrid, Spain, [6]Hospital Ramon y Cajal, Infectious Diseases, Madrid, Spain, [7]Hospital Universitario Ramon y Cajal, Madrid, Spain, [8]HGU Gregorio Marañon, Madrid, Spain*
*Presenting author email: tsainzcosta@gmail.com*

**Background:** Recent studies have confirmed a microbial gut dysbiosis in HIV adults on antiretroviral therapy (ART) that correlates with chronic bacterial translocation and systemic inflammation. Changes in microbial communities in vertically HIV-infected children, whose immune system has developed in the presence of the virus and bacterial products from the impaired gut, remain unexplored. We aim to characterize the intestinal microbiota of HIV-infected children compared to healthy children, and to modulate it using a nutritional supplement.
**Methods:** Pilot, double blind, randomized placebo-controlled study including HIV-infected children receiving a pre/probiotic supplement. DNA was extracted at baseline and after a 4-week intervention from stool samples and 16S rRNA gene amplicons were pyrosequenced. The sequences were analyzed using the Qiime pipeline. Bacterial biomarkers were identified using the LEfSe Biomarker discovery tool. Uninfected siblings were recruited as controls.
**Results:** 22 HIV-infected children completed the follow-up, and were compared to 11 controls. Mean age was 11.4±3.4, 8 (32%) were male. All were on ART and had VL< 50/ml. Their microbiota showed reduced alpha diversity compared to controls (P=0.042) and distinct composition at the genus level (Adonis P=0.042). Patients showed decreased abundance of commensals Faecalibacterium and Lachnospira and increase of the pathogenic Fusobacterium but not imbalance of Prevotella trade-off, as observed in adults. After the intervention, changes between the microbiota of cases and controls were non-significant and an increase of the butyrate producers Faecalibacterium and Butyricicoccus was documented.
**Conclusions:** Vertical HIV infection is characterized by intestinal dysbiosis despite ART, but the abnormalities at the compositional level are distinct to the ones observed in adults. Although not fully effective to restore the microbiota, a short intervention with pre/probiotics attenuated bacterial dysbiosis, increasing butyrate producing bacteria, which may play an anti-inflammatory role.

## ADHERENCE IN CHILDREN AND ADOLESCENTS

### TUPEB088

### SUCCESSFUL TRAINING OF HIV+ YOUTH IN A TRAUMA-INFORMED COGNITIVE BEHAVIORAL INTERVENTION FOR HIV+ ADOLESCENTS IN RWANDA

M.R. Fabri[1], J. Tuyishime[2], C. Umurungi[3], M.J. Maliboli[4], C. Ingabire[2], O. Uwimana[2], S. Nsanzimana[4], G. Donenberg[5], M. Cohen[6], Kigali Imbereheza Project- KIP
*[1]Women's Equity in Access to Care & Treatment (WE-ACTx), Mental Health, Chinle, United States, [2]WE-ACTx for Hope, Kigali, Rwanda, [3]CHUK, Kigali, Rwanda, [4]RBC, Kigali, Rwanda, [5]University of Illinois at Chicago, Chicago, United States, [6]Cook County Health and Hospital Systems, Chicago, United States*
*Presenting author email: mrfabri@hotmail.com*

**Background:** ART adherence among HIV+ adolescents is a global concern. Innovative responses include training peers to provide interventions. The Kigali Imbereheza Project (KIP) trained HIV+ Rwandan youth to deliver a trauma-informed cognitive behavioral intervention to improve adherence to ART in HIV+ adolescents. Rigorous training, supervision, and in-person mentoring were integral components of the program.
**Description:** Rwandan psychologists provided general counseling and group facilitation skills training to 16 youth leaders (YLs) (ages 21-25). US-based and Rwandan psychologists conducted 14 days of training, five-days on basic cognitive behavioral concepts and nine-days learning and practicing the structured six-session intervention. Four YL's were selected as facilitators (YFs), four as observers (YOs), based on demonstrated skills in practice sessions.
A RCT compared the intervention to standard of care. Rwandan psychologists provided supervision following each completed session and preparation prior to the next session. Individual supervision and training to increase knowledge was available as needed. Rwandan psychologists participated in weekly mentoring Skype calls with US-based psychologist. In addition, the US-based psychologist returned for in-person review and refresher trainings twice annually over the course of the study.
**Lessons learned:** To assess fidelity and skill, YFs were rated by YOs (e.g. followed script, explained and demonstrated activities, responded appropriately to questions). Ratings ranged from 0 "not very well" to 4 "very well." Observers mean ratings were between 3.25-3.83 indicating YF's performed "well" in adhering to curriculum and responding appropriately (e.g. praised correct responses, provided corrective feedback, limited unproductive discussion). YFs' self-evaluations were rated as: 1 "poor," 2 "fair," 3 "good," 4 "very good," 5 "excellent". YFs reported at least "good" for how well they delivered intervention except where one facilitator reported "fair." Measures by YOs and YFs suggest they learned and delivered with fidelity the trauma-informed cognitive behavioral intervention.
**Conclusions/Next steps:** With rigorous training and supervision, HIV+ youth can successfully provide mental health interventions. Monitoring and evaluating are important. Including biannual in-person mentoring with a senior psychologist promoted continuing skill development. The successful implementation of a cognitive behavioral intervention by YLs has important program implications within HIV care for adolescents and in-country capacity building.

### "IT IMPROVES OUR SKILLS TO HELP OUR CHILDREN": INVOLVING CAREGIVERS IN THE CARE OF HIV+ YOUTH IN RWANDA

C. Ingabire[1], J. Tuyishime[2], M. Gasana[3], O. Uwimana[2], C. Umurungi[3], G. Donenberg[4], S. Nsanzimana[5], M. Cohen[6], M.R. Fabri[7]

*[1]WE-ACTx for Hope, Research, Kigali, Rwanda, [2]WE-ACTx for Hope, Kigali, Rwanda, [3]CHUK, KIgali, Rwanda, [4]University of Illinois at Chicago, Chicago, United States, [5]RBC, Kigali, Rwanda, [6]Cook County Health and Hospital Systems, Chicago, United States, [7]WE-ACTx, Chinle, United States*

*Presenting author email: mardge.cohen@gmail.com*

**Background:** Caregiver and home environment are important sources of support for antiretroviral therapy adherence among adolescents with HIV. The Kigali Imbereheza Project (KIP) in Rwanda trained HIV+ youth leaders to conduct a six-session intervention for HIV+ adolescents utilizing trauma-informed cognitive behavioral strategies to improve adherence. Additionally, caregivers were invited to participate in two sessions focusing on assessing and improving child-caregiver relationships to support adherence.

**Methods:** KIP enrolled 198 14-21 year old, HIV+ youth and 187 identified caregivers in a 2-arm randomized controlled trial at two HIV treatment sites for adolescents in Kigali. Caregivers (biologic parent or guardian who lived with the youth) participated in two 2-hour sessions conducted by Rwandan study psychologists at midpoint and conclusion of the youth intervention period. Sessions were didactic and experiential with a focus on HIV knowledge and stigma, parent-child communication, and adherence problem solving strategies. Caregivers provided demographics and reported information on psychosocial variables and attitudes, including HIV knowledge and stigma. Data was collected using audio computer assisted technology at baseline, 6-, 12-, and 18-months. Using SPSS, we performed t-test analyses comparing change in scores from baseline to 6-months.

**Results:** The average age of a caregiver was 45 years, 78% were female, 60% had cared for youth their entire life, 59% were also HIV+, and 57% were single parents. Caregivers reported low income with 43% being currently employed. 89% were literate, 59% had completed primary education and 47% reported a mental health or substance abuse problem. Caregiver baseline data showed 82% had correct HIV knowledge, 76% reported supervising medication adherence 95% of the time, 94% indicated they ask youth about clinic visits, and 80% reported accompanying youth to clinic. Significant findings at six months post-intervention, showed that caregivers in the intervention group reported greater HIV knowledge (p=< .0001) and less HIV stigma (p=.0002) compared to baseline and compared to control group (p=.0084 and p=.0319 respectively).

**Conclusions:** In this study, the caregivers' intervention demonstrated improvement in HIV knowledge and reduction in HIV stigma that potentially will improve parent-child relationships, enhance antiretroviral adherence and improve health outcomes. Caregiver education is a valuable component of care for HIV+ adolescents.

## TUPEB090

### FACTORS ASSOCIATED WITH TREATMENT FAILURE AND DEVELOPMENT OF DRUG RESISTANCE AMONG HIV-1 INFECTED CHILDREN IN A SLUM-BASED TREATMENT PROGRAM IN KENYA

J. Mogire[1], E. Wairuri[2], L. Ochieng[3]

*[1]Queen Margaret University, Institute of Global Health and Development (IGHD), Musselburgh, United Kingdom, [2]AHF Kenya, Nairobi, Kenya, [3]AHF Kenya, Mathare Integrated Clinic, Nairobi, Kenya*

*Presenting author email: jobsm2005@yahoo.com*

**Background:** There's limited data from the developing countries on antiretroviral drug resistance among HIV-1 infected children failing antiretroviral therapy, especially in the context of extreme poverty and a high tuberculosis co-infection burden. We used treatment records to evaluate the risk factors for the development of HIV resistance-associated mutations among a cohort of slum-dwelling children.

**Methods:** We analyzed data of children that initiated antiretroviral therapy in a large slum-based clinic in Nairobi; we singled out all cases that had developed virological failure (WHO's definition: two consecutive viral loads >1000 copies/ml 3 months apart) between 2011 and 2013 and received genotypic drug resistance testing. We performed logistic regression analysis to determine frequencies of drug resistance mutations and related them to biomedical and socio-economic associations.

**Results:** We included 57 children (median age 27.8 months). At ART initiation, most had advanced clinical disease (78.3% WHO stage III or IV), high baseline HIV viral load (median 7.12 log10) and TB co-infection (73%), severe malnutrition (median weight-for-age Z-score -2.5, median height-for-age Z-score -2.9. All children were initiated on PI-based regimens. Median time-to-virological failure was 15.1 months (11.3-19.8, p< 0.03). The commonest mutations were M184V (41), V90M (13), and K103N (8). 34(59%) children had multi-class resistance mutations, in 16(47%) of whom M184V in reverse transcriptase was linked to PI resistance mutations. Factors co-related to presence of resistance mutations were: low weight-for-age and height-for-age (p=0.04; p=0.03); longer duration on PI regimens and virological failure (p=0.003; p=0.006); unsuppressed HIV viral load at 12, 24 and 36 months of ART (p=0.001); tuberculosis treatment at ART initiation (p=0.039); lack a regular primary care-giver (49% p=0.002), orphans (p=0.004), parent/guardian failing ART (p=0.002). Multivariate analysis showed significance of cumulative months on PI regimens and use of ritonavir as single PI (p=0.013; p=0.028).

**Conclusions:** Multiclass resistance mutations were the common in this cohort of HIV-1-infected children failing therapy. Duration of therapy, PI-regimen use, co-infection/TB treatment and lack of a consistent primary caregiver showed a multifactorial association to development of resistance. There's need for more interventions to address the treatment challenges of children in extreme poverty.

## TUPEB091

### BEYOND CLINICAL TRIALS: ASSOCIATIONS BETWEEN ANTIRETROVIRAL THERAPY (ART) AND REPORTING MULTIPLE MEDICATION SIDE-EFFECTS AMONG ADOLESCENTS IN SOUTH AFRICA

H.P. Mbaziira Natukunda[1,2], L. Cluver[1,3], E. Toska[1], A. Yakubovich[1], V. Musiime[4,5], The Mzantsi Wakho Adolescent Health Team

*[1]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [2]Medical Research Council, Pathology Department, Harwell, United Kingdom, [3]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [4]Makerere University College of Health Sciences, School of Medicine, Paediatrics and Child Health, Kampala, Uganda, [5]Joint Clinical Research Centre, Kampala, Uganda*

*Presenting author email: helenpretty75@yahoo.com*

**Background:** Pragmatic studies investigating ART-associated side-effects among adolescents in resource-limited settings are rare beyond clinical trial settings. This study examines cross-sectional associations between various ART regimens and reporting multiple medication side-effects, conducted with the largest community-traced sample of HIV-positive adolescents at present.

**Methods:** N=1059 ART-initiated adolescents aged 10-19 years attending 53 health facilities in Eastern Cape were interviewed and included in 2014-15. Adolescents also provided names and/or photographs of their current medication. Adolescents with unclear or missing medication/identification data (n=319, 30.1%) were excluded from analyses leaving a final sample of n=740 (69.9%).The major outcome—multiple medication side-effects (MMSEs)—was defined as experiencing 3 or more side-effects in the past 6 months by self-report. Potential confounders included age, gender, rural residence, overall health, food insecurity, lacking basic necessities, antibiotics/TB medication, pill burden, medication frequency, ART non-adherence, CD4 count < 500 cells/mm$^3$, recent treatment failure (viral load >1000 copies/mL), ART stock-outs, vertical infection and time on treatment. Multivariate logistic regression analyses followed by post-estimation computation of adjusted predicted probabilities for each ART were conducted in Stata 13.

**Results:** Prevalence of MMSEs was 61.0% (95% CI: 56.9-64.4). Prevalence of symptoms included in computing the outcome was: tiredness (44%), nausea/vomiting (42%), diarrhoea (42%), skin rash (42%), stomach problems (40%), dizziness (34%), insomnia/bad dreams (33%), ear problems (32%), weight loss (29%), and anxiety (3%). Frequent ART regimens were: Abacavir + Lamivudine + Efavirenz (ABC/3TC/EFV, n=165, 22%) and Tenofovir Disoproxil Fumarate + Emtricitabine + Efavirenz (TDF/FTC/EFV, n=116, 16%). NRTI-based regimens: ABC-containing (31%), TDF-containing (19%), Zidovudine (AZT)-containing (7%) and Stavudine (d4T)-containing (4%); NNRTI-based: EFV-containing (48%) and Nevirapine (NVP)-containing (0.4%); PI-based: Lopinavir/Ritonavir (LPV/r)-containing regimens (12%). d4T-containing regimens and the fixed dose combination containing TDF/FTC/EFV independently increased the likelihood of MMSEs (aOR: 2.83, CI: 1.14-6.99, p=0.025) and (aOR:1.66, CI: 1.05-2.62, p=0.029) respectively whereas LPV/r-based regimens were independently associated with fewer side-effects (aOR: 0.46, CI: 0.28-0.75, p< 0.005). The adjusted predicted probability of MMSEs was highest for d4T-containing regimens (82%), TDF/FTC/EFV (72%) and lowest for LPV/r-based ART (46%). However, findings from analyses linking ART to past-week non-adherence show that only TDF/FTC/EFV significantly reduced the likelihood of non-adherence among adolescents independent of clinic staff problems, clinic transport problems, food insecurity and past-year ART stock-outs (aOR: 0.51, CI: 0.32-0.82, p< 0.01).

**Conclusions:** d4T-containing and TDF/FTC/EFV-containing regimens are associated with many side-effects whereas LPV/r-containing regimens are associated with fewer side-effects among adolescents. However, adolescents on TDF/FTC/EFV were the most adherent subgroup. These findings underpin the importance of once daily cART in the management of adolescent HIV and provide the evidence needed to enable clinicians achieve a balance between the decision to prescribe low toxicity ART with the imperative to promote adherence amongst adolescents.

## TUPEB092

### FIRST-LINE ART REGIMEN DURABILITY AMONG SOUTH AFRICAN HIV-POSITIVE PEDIATRIC PATIENTS

R. Bonawitz[1,2], A. Brennan[1,3], L. Long[4], I. Sanne[4,5,6], T. Heeren[7], D. Thea[1], M. Fox[3,4]
*[1]Boston University School of Public Health, Department of Global Health, Boston, United States, [2]Boston University School of Medicine, Department of Pediatrics, Boston, United States, [3]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [4]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [5]University of the Witwatersrand, Clinical HIV Research Unit, Department of Internal Medicine, Johannesburg, South Africa, [6]Right to Care, Johannesburg, South Africa, [7]Boston University School of Public Health, Department of Biostatistics, Boston, United States*
*Presenting author email: rebonawi@bu.edu*

**Background:** Regimen durability is crucial for survival to adulthood. In South Africa, first-line ART for children older than five years was stavudine-based (d4T) until April 2010, when tenofovir (TDF) replaced d4T. We investigated predictors of single-drug substitutions (SDS), treatment interruptions (TI), and switches to second-line therapy (SLT).
**Methods:** Prospective study of patients 5-19.9 years initiating ART between April 2004-April 2012 at 8 public-sector HIV clinics. SDS was defined as change of nucleoside reverse transcriptase inhibitor without switching to SLT; TI was defined as ART cessation; SLT switch was defined by at least two drug changes across two classes. Adjusted Cox models were used to determine predictors of outcomes.
**Results:** 1978 children were eligible. Over 24-months follow-up, 310 (15.7%) SDSs; 67 (3.4%) SLT switches and 304 (15.4%) TI occurred. SDS frequency peaked in 2010 (24%), then declined in 2011 (11%). TI peaked in 2006 (22%) with decline in 2011 (12%), while SLT switches remained near 5%. Patients initiated on d4T (vs. TDF) had a 500% increase in the hazards of SDS (HR 6.01, 95% CI 2.2-16.41). ART initiation in 2009 and 2010 (vs. 2011) had a 100% increase in the hazards of SDS (HR 2.16, 95% CI 1.14-4.11). Initiation on d4T trended towards increased hazards of TI (HR 1.52, 95% CI 0.9-2.56). ART initiation in 2006 (vs. 2011) had 100% increase in the hazards of TI (HR 2.03, 95% CI 1.07-3.87). Neither initiation on d4T or year of initiation was associated with increase in SLT switch.
**Conclusions:** The SDS peak in 2010 likely resulted from treatment-experienced patients switching from d4T to TDF. Declines in SDS and TI may have resulted from fewer side-effects/toxicities from TDF, but TDF initiation doesn't account for decreased TI since 2006. The proportion of SLT switches hasn't changed, though regimen durability overall has improved after introduction of TDF.

*Presenting author email: gem.patten@uct.ac.za*

**Background:** Treatment failure in HIV-infected children on antiretroviral therapy (ART) in resource-limited settings is a growing concern given poor access to new drugs and lack of targeted strategies to improve adherence. Lamivudine monotherapy (LM) has been used as a holding regimen whilst psychosocial barriers to adherence are addressed. There are few studies of LM outcomes in children. We aimed to investigate characteristics of children placed on LM and their outcomes.
**Methods:** We included children (age < 16 years at ART start) who received LM. Kaplan-Meier estimates and Cox-proportional hazards modelling were used to determine probability and predictors of immunological failure (IF), defined as a drop in CD4 below 500, or, in those who initiated LM with CD4< 500, a drop in CD4 of > 10%. The Wald's test was used to obtain p-values for categorical variables.
**Results:** Characteristics and outcomes of patients on LM are summarized in table 1.

| Characteristics at ART start | Male (%) | 117 | 62% | Outcomes on LM | Median time in days on LM | 310 | (85-671) |
|---|---|---|---|---|---|---|---|
| | Median age in years (IQR) | 6.8 | (2.4-9.7) | | Resumed ART (n,%) | 121 | 64% |
| | Median CD4 count (IQR) (n=130) | 345.5 | (176-583) | | Remained in care on LM (n,%) | 46 | 24% |
| | Median CD4% (IQR) (n=126) | 13.0 | (7.6-18.0) | | Died on LM (n,%) | 3 | 2% |
| Characteristics at LM start | Median age in years (IQR) | 11.1 | (6.5-13.9) | | Transferred out on LM (n,%) | 11 | 6% |
| | Median CD4 count (IQR) (n=177) | 613 | (427-868) | | Lost to follow-up on LM (n,%) | 8 | 4% |
| | Median CD4% (IQR) (n=177) | 23.0 | (16.9-28.2) | | | | |
| | CD4 < 500 cells/uL (n=177) | 59 | 33% | | | | |
| | Median VL (IQR) (n=178) | 13291 | (4085-51000) | | | | |
| | On efavirenz-based regimen (%) | 102 | 54% | | | | |

*[Characteristics of children on lamivudine monotherapy (LM) from 5 IeDEA-SA cohorts (N=189)]*

Of those on LM for >90 days, 42% (55/130) experienced IF; 21% (27/130) experiences a gain in CD4 of > 10%. Among 102 patients on LM for > 6 months, the 6 month risk of IF was 22% (95% CI 15.9%-29.9%). Predictors of IF included older age, treatment interruptions prior to LM start, immunosuppression at ART start, and CD4 at LM start (Table 2). Ever having been on a PI regimen was not associated with IF.

| Characteristic at ART or LM start | | Adjusted HR (95% CI), n=130 | p | Characteristic at ART or LM start | | Adjusted HR (95% CI), n=130 | p |
|---|---|---|---|---|---|---|---|
| Age in years at ART start | <2 | 1 | - | Immune suppression at ART start | Not immune suppressed | 1 | - |
| | 2-6 | 2.05 (0.90-4.68) | 0.0213 | | Immune suppressed | 2.25 (1.18-4.3) | 0.0439 |
| | 6-9 | 2.82 (1.38-5.76) | | | Missing | 2.10 (1.06-4.17) | |
| | >9 | 3.07 (1.39-6.79) | | Ever on a PI-based regimen | | 1.08 (0.68-1.72) | 0.738 |
| Prior Treatment Interruption | | 2.27 (1.32-3.88) | 0.003 | | | | |
| CD4 at LM start | <500 | 1 | - | | | | |
| | 500-750 | 1.28 (0.77-2.15) | 0.014 | | | | |
| | 750-1000 | 0.91 (0.46-1.78) | | | | | |
| | >=1000 | 0.42 (0.20-0.89) | | | | | |

*[Mulitvariate associations with a decline in CD4 of > 10% from LM start or a drop in CD4 count <500 cells/uL in those with CD4>500, stratified by site]*

**Conclusions:** Most children on LM experienced immunologic decline. The clinical significance of this decline warrants further investigation including comparison with those who interrupt treatment or remain on triple therapy.

## TUPEB094

### ADHERENCE MEASUREMENT AND SUPPORT SERVICES FOR HIV-INFECTED CHILDREN AND ADOLESCENTS FOLLOWED IN GLOBAL SITES OF THE INTERNATIONAL EPIDEMIOLOGIC DATABASES TO EVALUATE AIDS (IEDEA)

R. Vreeman[1,2], S. Ayaya[2,3], A. Sohn[4], A. Edmonds[5], M.L. Lindegren[6], R. Hazra[7], E. Arrive[8,9], L. Feinstein[5], K. Razali[10], J. Pinto[11], B. Musick[1,2], M.-A. Davies[1,2], C. McGowan[6], V. Leroy[12], K. Wools-Kaloustian[1,2], the International Epidemiologic Databases to Evaluate AIDS (IeDEA) Consortium

*Presenting author email: kwools@iu.edu*

**Background:** Sustaining adherence to antiretroviral therapy (ART) is central to successful long-term HIV care for children and adolescents. We do not know the most effective strategies to improve adherence in resource-limited settings or have a clear picture of the services currently available. We sought to describe how global HIV care programs measure and support pediatric ART adherence.

**Methods:** Using a web-based survey (REDCap), we assessed adherence measurement, support services, and relevant pediatric care system characteristics at sites caring for pediatric patients in 6 global regions of the International Epidemiologic Databases to Evaluate AIDS (IeDEA) consortium.

**Results:** Clinical staff from 180 pediatric sites in 45 countries completed the adherence survey between June 2014-March 2015. Sites were in Asia (n=16 sites; 4,357 children), Central and South America (n=7; 1,746 children), Central Africa (n=18; 906 children), East Africa (n=33; 12,218 children), Southern Africa (n=95; 45,641 children), and West Africa (n=11; 8,932 children.) Most sites managed both adults and children (82%). Open clinician adherence assessment (used at 87% of sites) and pharmacy refills (86% of sites) were the most common adherence measurement methods used globally (Table 1). All sites used at least one measure. Structured recall items (77%) and targeted HIV viral loads (75%) were also common. Available adherence support services varied widely across sites, with counseling most common and few sites using SMS reminders (Table 2).

| Adherence Measure | Asia-Pacific (16 sites) | Latin America (7 sites) | Central Africa (18 sites) | East Africa (33 sites) | Southern Africa (95 sites) | West Africa (11 sites) |
|---|---|---|---|---|---|---|
| Clinical Assessment | 13 (81%) | 7 (100%) | 13 (72%) | 22 (67%) | 93 (98%) | 9 (82%) |
| Structured Recall (one recall item, any time period) | 7 (44%) | 3 (43%) | 14 (78%) | 20 (61%) | 87 (92%) | 8 (73%) |
| Instrument with Multiple Adherence Questions | 4 (25%) | 0(0%) | 7 (39%) | 16 (48%) | 78 (82%) | 5 (45%) |
| Pill Counts | 10 (63%) | 2 (29%) | 14 (78%) | 27 (82%) | 13 (14%) | 6 (55%) |
| Liquid Measures | 5(31%) | 2(29%) | 12(67%) | 8(24%) | 8(8%) | 5 (45%) |
| Pharmacy Refills | 7 (44%) | 4(57%) | 16 (89%) | 27(82%) | 90 (95%) | 10 (91%) |
| Electronic Dose Monitoring | 0(0%) | 0(0%) | 0(0%) | 1(3%) | 3(3%) | 0(0%) |
| Viral Load Monitoring at Routine Intervals | 10 (63%) | 5(71%) | 13(72%) | 26(79%) | 12(13%) | 8(73%) |
| Viral Loads if Suspect Non-Adherence | 9 (56%) | 3(43%) | 14(78%) | 16(48%) | 86(91%) | 7(64%) |

*[ART Adherence Measurement Methods Used for Children by Global IeDEA Sites]*

| Adherence Support Available | Asia (16 sites) | Latin America (7 sites) | Central Africa (18 sites) | East Africa (33 sites) | Southern Africa (95 sites) | West Africa (11 sites) |
|---|---|---|---|---|---|---|
| Pill Boxes | 12 (75%) | 2 (29%) | 1 (6%) | 9 (27%) | 8 (8%) | 2 (18%) |
| Counseling (Any) | 16 (100%) | 7 (100%) | 16 (89%) | 32 (97%) | 89 (94%) | 10 (91%) |
| Case Management | 13 (81%) | 5 (71%) | 13 (72%) | 28 (85%) | 89 (94%) | 10 (91%) |
| Educational Classes | 9 (56%) | 3 (43%) | 15 (83%) | 29 (88%) | 89 (94%) | 8 (73%) |
| Support Groups: For caregivers For children | 13 (81%) 9 (56%) | 6 (86%) 5 (71%) | 12 (67%) 13 (72%) | 28 (85%) 26 (79%) | 88 (93%) 92 (97%) | 8 (73%) 9 (82%) |
| Peer adherence supporters | 3 (19%) | 2 (29%) | 10 (56%) | 25 (76%) | 87 (92%) | 5 (45%) |
| Home Visits | 10 (63%) | 4 (57%) | 17 (94%) | 25 (76%) | 81 (85%) | 8 (73%) |
| SMS Adherence Reminders | 4 (25%) | 2 (29%) | 1 (6%) | 9 (27%) | 2 (2%) | 1 (9%) |
| Nutritional Support | 12 (75%) | 4 (57%) | 14 (78%) | 32 (97%) | 88 (93%) | 9 (82%) |

*[ART Adherence Support Available at Global IeDEA Sites]*

**Conclusions:** Global pediatric HIV care services routinely measure adherence, but few use objective or validated measures. General support services are available, but more targeted adherence support may not be present.

## TUPEB095

### DOES NEUROCOGNITIVE FUNCTION AND/OR ANXIETY/DEPRESSION PREDICT ADHERENCE TO ANTIVIRAL THERAPY AMONG PERINATALLY HIV-INFECTED ADOLESCENTS IN ENGLAND?

A. Judd[1], F. Parrott[1], D. Melvin[2], C. Foster[2], M. Le Prevost[1], M. Evangeli[3], A. Winston[4], A. Arenas-Pinto[1], K. Sturgeon[1], K. Rowson[1], D. Gibb[1]
[1]*University College London (UCL), MRC Clinical Trials Unit, London, United Kingdom,* [2]*Imperial College Healthcare NHS Trust, London, United Kingdom,* [3]*Royal Holloway University of London, London, United Kingdom,* [4]*Imperial College London, London, United Kingdom*
*Presenting author email: a.judd@ucl.ac.uk*

**Background:** Perinatally HIV-infected (PHIV) young people are entering adulthood, often with complex clinical and psychosocial issues which may affect adherence to ART. This is at a time when they are increasingly expected to self-manage their HIV care.

**Methods:** 296 PHIV aged 13-21 years were recruited into the AALPHI cohort in England from 2013-15. Baseline data included (via computer-assisted self-interview) short-term adherence (any v. no missed doses in last three days), anxiety/depression (HADS), quality of life (PedsQL), drug/alcohol use, and self-perception about having HIV (composite score of level of upset, worry, sadness, loneliness, concern

about future health). A summary (NPZ-6) z-score was calculated for neurocognitive function. Logistic regression examined predictors of short-term non-adherence.
**Results:** 261(88%) of 296 PHIV were on ART (94% once-daily) at recruitment. 111(43%) were male, 220(84%) black, median age was 16 years [IQR 15,18] and for 87(35%) one/both biological parents had died. 72(28%) had CDC Stage C; 78% had viral load (VL) ≤50copies/ml. 242(93%) were in full-time education, 236(91%) lived with their parents/carers, and 50(19%) had transferred to adult care. 17% and 5% had moderate/severe anxiety and depression respectively, and mean NPZ-6 score was -0.58(SD 0.86).
Overall 70(27%) reported missing ≥1 ART dose in the last 3 days, most often due to forgetting (68%) and being away from home (37%). Of those with VL>50copies/ml, 51% reported missing doses, vs. 20% for those with VL< 50. Multivariable analysis (Table) identified those with decreased QL, negative perceptions about having HIV, and cigarette smokers, as having higher odds of non-adherence. Anxiety/depression, NPZ-6, CDC C diagnosis, alcohol/drugs, and having transferred to adult care did not predict adherence.

| Variable | | Adjusted Odds Ratio (95% CI) | P value |
|---|---|---|---|
| Quality of life (PedsQL) | Per 100 units decreased quality of life | 1.1 (1.0, 1.2) | 0.029 |
| Perception about having HIV | Per 5 units decreased (negative) score | 1.1 (1.0, 1.2) | 0.043 |
| Ever smoked cigarettes | No | Ref | |
| | Yes | 2.7 (1.3, 5.7) | 0.010 |
| *All variables adjusted a priori for gender, age at interview, born UK v. abroad, ethnicity | | | |

*[Table: Multivariable* predictors of 3 day non-adherence]*
**Conclusions:** More than one in four PHIV reported poor adherence to ART in the previous three days. Lower quality of life, poorer perception about having HIV, and cigarette smoking were the main predictors of recent non-adherence. Cognitive function and anxiety /depression may act as mediating influences for these associations rather than directly predicting adherence.

## TUPEB096

### AN ADHERENCE INTERVENTION AND DRUG RESISTANCE AMONG HIV-POSITIVE ADOLESCENTS FAILING SECOND-LINE TREATMENT AT A PUBLIC HEALTH CLINIC

T.D. Chawana[1], B. Ngara[2], K. Nathoo[3], D. Katzenstein[4], C. Nhachi[1], ATF Study
*[1]University of Zimbabwe, Clinical Pharmacology, Harare, Zimbabwe, [2]University of Zimbabwe, Community Medicine, Harare, Zimbabwe, [3]University of Zimbabwe, Paediatrics, Harare, Zimbabwe, [4]Stanford University, Division of Infectious Diseases, San Francisco, United States*
*Presenting author email: tdchawana@gmail.com*

**Background:** Sustaining virologic suppression among HIV-infected adolescents is challenging due to poor adherence. From 20-50% fail 2nd line ART. Enhanced adherence support may improve treatment outcomes. This study sought to characterize self-reported adherence and drug resistance mutations among adolescents failing 2nd line treatment and evaluate a home-based adherence intervention with SMS test outreach compared to standard care.
**Methods:** HIV positive participants aged 10-18 years on boosted atazanavir-based 2nd line treatment from a public clinic in Zimbabwe with virologic failure (VL ≥1 000 copies/ml) were randomized to standard care (SC) or modified directly administered antiretroviral therapy (mDAART) for 3 months. SC included 3 monthly clinic reviews and adherence counseling. The mDAART intervention included SC, home visits and SMS outreach by research assistants. Viral load was measured and questionnaires administered at baseline and at 3 months after enrolment. Genotyping was done for participants with continued treatment failure. Primary outcome was suppression to VL < 1 000 copies/ml evaluated by Fisher's test. Data was recorded in Redcap.
**Results:**

| Variable | Outcome (n=33) |
|---|---|
| Age, mean(SD); range in years | 15.8 (1.6); 13 - 18 |
| Gender: Female Male | 67% 33% |
| Baseline self-reported adherence by visual analogue scale (VAS): ≥95% 80-94% <80% | 29% 29% 42% |
| Post self-reported adherence by VAS : ≥95% 80-94% <80% | 45% 30% 25% |
| Self-reported adherence by VAS: Decreased Increased | 20% 80% |
| Baseline viral load, median (range) copies/ml | 77 022 (1 501 - 6 279 197) |
| Post viral load , median (range) copies/ml | 23 720 (20 - 736 198) |
| Viral load change: Decreased Increased | 18 (67%) 9 (33%) |
| % with re-suppression at 3 months (VL< 1 000copies/ml) | 33.3% |

*[Participant characteristics]*

Time on 2nd line ART, mean (SD); range months was 19.4 (6.0); (8.8 - 29.8) months.

| Variable | SC (n=15) | mDAART (n=18) | p-value |
|---|---|---|---|
| Age, mean (SD) in years | 16.0 (1.5) | 15.6 (1.7) | 0.568 |
| Gender-Female | 80% | 55.6% | 0.339 |
| Time on 2nd line ART, mean (SD) in months | 18.0(5.1) | 19.8(8.3) | 0.5104 |
| Increased self-reported adherence (VAS) | 56% | 100% | 0.026 |
| Decreased viral load | 57% | 71% | 0.445 |
| % with re-suppression at 3 months (VL< 1 000copies/ml) | 13.3% | 50% | 0.0342 |

*[Association between treatment arms with outcome]*

Treatment arms were well matched. Genotyping was done in 20/22 participants with continued failure. [n(%)] of resistance mutations by ARV class were: PIs- Q58E [2(10.5%)]; V82M, L90M, A71T, L10F, M46I, A71I, I84V and I50L [1(5.3%)]. NNRTIs-Y181C [7(36.8%)]; G190A [6(31.6%)]; A98G [5(26.3%)] and K103N [3(15.8%)]. NRTIs-M184V [6(31.6%)]; D67G, T69N and M41L [5(26.3%)]; K70R, T69D, V75I and T215F [3(15.8%)]. High level atazanavir resistance was identified in 2(6.1%) continued virologic failures.
**Conclusions:** The mDAART intervention resulted in improved self-reported adherence and virologic suppression. High level atazanavir resistance was demonstrated.

## TUPEB097

### ADHERENCE TO ANTIRETROVIRAL TREATMENT (ART) AMONG ADOLESCENTS IN NAIROBI COUNTY, KENYA

P. Memiah[1], J. Mbizo[1], B. Onyuka[2], A. Igowu[3], C. Kingori[4], A. Hill[1], C. Swain[1], M. Wairimu[5], K. Owour[6]
*[1]University of West Florida, Public Health, Penscaola, United States, [2]Save the Children, Health Information Systems, Nairobi, Kenya, [3]Morgan State University School of Community Health and Policy, Department of Public Health Analysis, Baltimore, United States, [4]Ohio University, Social and Public Health, Athens, United States, [5]University of North Carolina, Charlotte, United States, [6]USAID-FIRM Project, Nairobi, Kenya*
*Presenting author email: pmemiah@gmail.com*

**Background:** AIDS is the leading cause of death among adolescents in Africa and the second leading cause of death among adolescents globally. Despite adherence to ART being critical in controlling viral replication, maintaining health and reducing onward viral transmission, there are limited data on ART adherence amongst Adolescents and Youth globally. We undertook a study to examining the factors associated with poor ART adherence among adolescents in Nairobi County.
**Methods:** The study utilized routinely collected patient-level data for antiretroviral treatment (ART)-naive HIV-infected patients, aged 10-24 years. The total sample of 1800 adolescents had been enrolled in care between 2006-2015 at 16 Health Facilities in Nairobi. The dependent variable was adherence to HAART. Less than 95% adherence was considered "poor". Chi square tests and logistic regression analysis was used to examine the relationship between explanatory variables (Socio- demographic and Clinical and Immunological) and adherence to ART.
**Results:** The median age at enrollment was 20.9 (IQR: 18.5,22.6). Females comprised of 81.6% of the sample. On bivariate analysis, youth on ART for more than 1 year comprised of significantly higher proportion of those with poor adherence compared to good adherence (p = 0.028). Clients with WHO staging 3 or 4 also comprised of significantly higher proportions of poor adherence compared to good adherence (p < 0.001). The logistic model found poor adherence was trending towards association with: age (OR=2.73); having a higher CD4 (1.03) having a longer duration on ART >1 year (OR= 1.73), lower WHO stage (OR=5.36); ever using a family planning method (OR=3.13); and longer duration of time between HIV testing and ART start (OR=2.02).
**Conclusions:** This study suggest the importance for health facilities and HIV youth-centered organization to address:
1) age-specific challenges of adherence;
2) longer duration on ART, and
3) sexual behavior.
The first step toward addressing the problem of non-adherence is to accurately identify patients whose risk is sufficient to undermine clinical outcomes (viral suppression). Further research from the program data will assist in obtaining a better understanding of the etiology of poor adherence and to design effective intervention to improve adherence in Kenya.

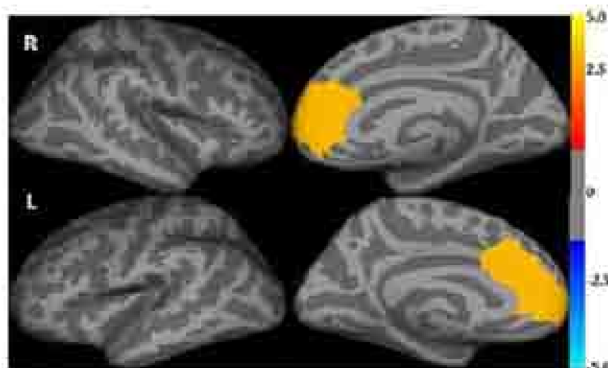
# COMPLICATIONS OF HIV AND THEIR THERAPY IN CHILDREN AND ADOLESCENTS

## TUPEB098

### GYRIFICATION DIFFERENCES IN 7 YEAR OLD HIV-INFECTED CHILDREN STARTING ART BEFORE OR AFTER 12 WEEKS OF AGE

E.C. Nwosu[1], F.C. Robertson[1], M.J. Holmes[1], M.F. Cotton[2], E. Dobbels[2], F. Little[3], B. Laughton[2], E.M. Meintjes[1], A. van der Kouwe[4,5]
*[1]University of Cape Town, MRC/UCT Medical Imaging Research Unit, Department of Human Biology, Cape Town, South Africa, [2]Stellenbosch University, Family Clinical Research Unit, Department of Paediatrics & Child Health, Tygerberg Children's Hospital and Faculty of Health Sciences, Cape Town, South Africa, [3]University of Cape Town, Department of Statistical Sciences, Faculty of Sciences, Cape Town, South Africa, [4]Massachusetts General Hospital, A.A. Martinos Centre for Biomedical Imaging, Department of Radiology, Charlestown, United States, [5]Harvard Medical School, Department of Radiology, Boston, United States*
*Presenting author email: emmanuel.c.nwosu@gmail.com*

**Background:** Early antiretroviral therapy (ART) has been found to improve outcomes for HIV-infected infants, however, long-term effects on brain development require further investigation. This study used magnetic resonance imaging (MRI) to compare brain morphometry in 7-year-old vertically-infected children who started ART before or after 12 weeks of age.
**Methods:** MRI scans were done on participants from the follow-on study of the Children with HIV early Anti-retroviral (CHER) trial without sedation according to protocols approved by the Ethics Committees of Universities of Cape Town and Stellenbosch. FreeSurfer software v5.1.0 was used for automated segmentation and reconstruction. Whole-brain cortical thickness and gyrification - measure of cortical folding - and regional brain volumes were compared between children who started ART after 12 weeks and those who started before 12 weeks and to HIV-unexposed (HU) controls using a linear regression model controlling for sex and duration of ART interruption.
**Results:** Sixty-one HIV-infected isiXhosa children (28 boys, age 7.21 ± 0.12 years) and 23 HU (13 boys, age 7.24 ± 0.18 years) controls were scanned. 46 HIV-infected children started ART before (Before-12w) (28 interrupted), while 15 started after 12 weeks of age (After-12w). Cortical thickness and regional volumes did not differ between After-12w and Before-12w children. After-12w children had significantly greater gyrification than Before-12w children in a large bilateral medial frontal region ($p< 0.05$), where there was also positive association between age at ART initiation and gyrification (Figure 1). Before-12w children had less gyrification than HU controls in an overlapping right frontal region ($p< 0.05$) but there was no difference between After-12w children and HU controls in this region at the same significance level.



*[Figure 1. Yellow regions show clusters of points on the medial frontal brain surface where age at ART initiation showed a positive relationship with gyrification at a significance threshold of p<0.05]*

**Conclusions:** Gyral formation in childhood is sensitive to ART initiation timing. ART started before 12 weeks, irrespective of interruption, may impact development of cortical folding during early critical period compared to delayed ART.

## TUPEB099

### THE ROLE OF *APOL1* VARIANTS IN THE DEVELOPMENT OF FOCAL SEGMENTAL GLOMERULOSCLEROSIS IN SOUTH AFRICAN CHILDREN WITH IDIOPATHIC AND HIV-RELATED NEPHROTIC SYNDROME

W.P. Qulu[1], R. Bhimma[1], B. Sartorius[2], E. Naicker[3], K. Asharam[4], T. Naicker[5], C. Winkler[6]
*[1]University of KwaZulu Natal, Paediatrics and Child Health, Durban, South Africa, [2]University of KwaZulu Natal, Public Health Medicine, Durban, South Africa, [3]Albert Luthuli Central Hospital, Paediatric and Child Health, Durban, South Africa, [4]University of KwaZulu Natal, Ocupational and Environmental Health, Durban, South Africa, [5]University of KwaZulu Natal, Optics and Imaging Center, Durban, South Africa, [6]National Cancer Institute, Centre for Cancer Research, Frederick, United States*
*Presenting author email: wenkosi.qulu@yahoo.com*

**Background:** Kidney disease is more frequent and its advancement to end-stage kidney disease occurs more rapidly among patients of African ancestry compared to other racial groups. Coding variants with the APOL1 gene are strongly associated with kidney diseases in patients of African ancestry. This study aims to determine the role of genetic variants at the *APOL1* locus in the development of focal segmental glomerulosclerosis (FSGS) in South African children with idiopathic and HIV-related nephrotic syndrome.
**Methods:** Ethical approval was obtained from the Biomedical Research Ethics Committee, University of KwaZulu-Natal. Patient recruitment was conducted at Inkosi Albert Luthuli Central Hospital and King Edward VIII Hospital, KwaZulu-Natal South Africa. The study population consisted of 163 Black South African children (ages 0-16yrs) with biopsy proven idiopathic FSGS (n=56), HIV associated nephrotic syndrome (n=14), patients without nephrotic syndrome or other renal disease (n=76) and HIV-1 infected patients without nephrotic syndrome or other renal disease (n=17). We genotyped three SNPs rs73885319, rs60910145 and rs71785313 utilizing a Taqman pre-designed genotyping assay.
**Results:** Our results demonstrated no significant association with the *APOL1* rs73885319 risk variant across the study groups. A majority of the HIV $^{+}$FSGS patients (10/14 or 71.4%) showed no presence of the APOL1 G1 and G2 risk alleles. Fifty three percent of patients with idiopathic FSGS (HIV$^{-}$) showed no presence of the APOL1 G1 and G2 risk alleles. In the HIV $^{+}$FSGS patients, G1 risk allele frequencies were 2/14 or 14% whilst G2 deletion was 2/14 or 14%. In the idiopathic FSGS group, the odds of carrying two copies of G1 and/or G2 risk alleles was 2.4 (95%CI 0.26 to 30, $p$=0.38) and Inf (0.03, inf, $p$=0.45) for the HIV with FSGS in a recessive model.
**Conclusions:** This novel study demonstrates no association between the *APOL1* risk variants and biopsy proven HIV associated FSGS and idiopathic FSGS in paediatric Black South African population within the KwaZulu-Natal region of South Africa.

## TUPEB100

### LONG-TERM MAINTENANCE OF UNDETECTABLE VIRAL IS ASSOCIATED WITH BETTER RESPONSE TO IMMUNIZATION WITH *NEISSERIA MENINGITIDIS* C CONJUGATED VACCINE AMONG HIV VERTICALLY-INFECTED CHILDREN, IN RIO DE JANEIRO, BRAZIL

A.C. Frota[1], L. Milagres[2], B. Ferreira[1], D. Menna-Barreto[1], G. Pereira[2], R. de Castro[2], L. Harrison[3], L. Evangelista[1], T. Abreu[1], R. de Oliveira[1], C. Barroso Hofer[1]
*[1]UFRJ, Rio de Janeiro, Brazil, [2]UERJ, Rio de Janeiro, Brazil, [3]University of Pittsburgh, Pittsburgh, United States*
*Presenting author email: cbhofer@hucff.ufrj.br*

**Background:** Immunization guidelines use CD4 cells count and/or percent as the main condition to immunize HIV infected children. The impact of undetectable viral load in children with high CD4 cells at immunization was not evaluated. The aim of this is study is to compare the immune response after two doses (12-18 months interval between doses) of *Neisseria meningitidis* C conjugated vaccine (C Polysaccharide/$CRM_{197}$) at dose (10 µg/0.5 ml) between individuals who were able to maintain undetectable viral load (UVL) through study follow up (at least 12 months) or not (non-UVL).
**Methods:** HIV vertically-infected patients, aged 2-18 years old, with CD4+ cell > 15% or 350 cell/mm$^3$, without active infection were immunized. One month after the second dose, post-immunization protective antibody titer, defined as a serum bactericidal assay(SBA) ≥ 1:4 (with human complement), was evaluated. Children were classified as responders SBA≥1:4 or otherwise non-responders. The Bivariate analysis was performed, and variables with p-value < 0.15 were independently evaluated through logistic regression analysis.
**Results:** 124 children using cART before the study initiation were enrolled: 62 (50%) were able to maintain UVL through the follow up. The median of study follow up was 13.1 and 13.3 months for UVL and non-UVL group respectively, p=0.11. At the study entry, the median of cART duration was 6.2 years for UVL and 6.4 for non-UVL, p=0.71. 57 (92%) and 41 (66%) were able to present immune response

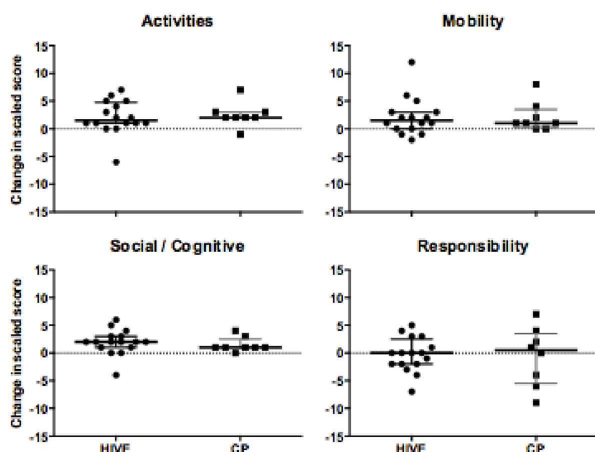
to the vaccine (responders) in the UVL and the non-UVL groups, respectively p< 0.01. The median age was 12.5 years for the non-responders group and 12 for the responders, p=0.14. 53 (57%) were female in the responders group and 13 (50%) in non-responders, p=0.52. Among the non-responders the median of the CD4 cells percent was 26% in the non-responders group and 29% in the responders, p< 0.01. Factors associated with protective antibody concentration were: maintenance of UVL through study (OR=5.1, 95%CI=1.7-14.9) and higher CD4 cells percent at the study entry (OR=1.1, 95%CI=1.0-1.2).
**Conclusions:** Although the CD4 cell percent is an important variable associated with immunization response, long-term maintenance of undetectable viral load must also be considered when planning immunization of HIV infected children.

## TUPEB101

### CHANGE IN LEVEL OF ACTIVITY AND PARTICIPATION IN CHILDREN WITH HIV ENCEPHALOPATHY AND BILATERAL LOWER LIMB SPASTICITY COMPARED TO CHILDREN WITH CEREBRAL PALSY: A ONE YEAR FOLLOW-UP STUDY

B.E. Veerbeek[1], T.N. Mann[1,2], B. Laughton[3], K.A. Donald[4], N.G. Langerak[1]
*[1]University of Cape Town, Neurosurgery, Cape Town, South Africa, [2]Stellenbosch University, Orthopaedic Surgery, Cape Town, South Africa, [3]Stellenbosch University, 3Children's Infectious Diseases Clinical Research Unit, Department of Paediatrics and Child Health, Cape Town, South Africa, [4]Red Cross War Memorial Children's Hospital, University of Cape Town, Paediatrics and Child Health, Cape Town, South Africa*
*Presenting author email: nellekelangerak@hotmail.com*

**Background:** Level of daily activity and participation in children with HIV encephalopathy (HIVE) and bilateral lower limb (BLL) spasticity is unclear, creating uncertainty in the management of secondary abnormalities. Should these children receive the same surgical interventions as children with BLL spasticity due to Cerebral Palsy (CP)? The first aim of the study was to investigate change in level of activity and participation over one year in children with BLL spasticity due to HIVE and due to CP. A secondary aim was to compare the magnitude of the change between children with HIVE and with CP.
**Methods:** This one year follow-up study (1.1 ± 0.2 years) was based on 16 children with BLL spasticity due to HIVE (8.8 ± 2.2 years, 10 girls) and 8 children with BLL spasticity due to CP (8.7 ± 2.0 years, 3 girls), who were recruited in state hospitals in Cape Town, South Africa. The Computer-Adapted Pediatric Evaluation of Disabilities Inventory (PEDI-CAT) was used to determine the level of activity (Activity, Mobility and Social/Cognitive domains) and participation (Responsibility domain). A Wilcoxon test was used to address aim 1, and a Mann-Whitney test for aim 2.
**Results:** HIVE and CP groups both showed a significant increase in score for the Activities, Mobility and Social/Cognitive domains (p≤0.01) with no significant change in Responsibility domain score (p=0.84). In addition, there was no significant difference in the median change in score over 1 year between the HIVE and CP groups for any of the PEDI-CAT domains (p>0.05) (Figure 1).



*[Figure 1. Change in PEDI-CAT scores between baseline and one year follow-up study for Activity, Mobility, Social/Cognitive and Responsibility domains]*

**Conclusions:** These findings suggest little change in participation over time, while level of daily activity in the HIVE and CP group improved with similar magnitude. Although the changes are statistically significant, the clinical significance is unclear. More research is needed to provide evidence-based guidelines for surgical interventions in this HIVE population.

# COMORBIDITIES IN CHILDREN AND ADOLESCENTS (INCLUDING NON-COMMUNICABLE DISEASES)

## TUPEB102

### A HOSPITAL BASED CROSS-SECTIONAL OBSERVATIONAL STUDY OF COGNITIVE, ADAPTIVE AND BEHAVIOUR PROFILES OF 2-9 YEAR OLD HIV-INFECTED AND HIV-AFFECTED CHILDREN

S. Mukherjee[1], S. Devamare[1], A. Seth[1], S. Sapra[2]
*[1]Lady Hardinge Medical College, Pediatrics, New Delhi, India, [2]AIIMS, Pediatrics, New Delhi, India*
*Presenting author email: theshormi@gmail.com*

**Background:** This study aimed to compare cognitive, adaptive and behavior profiles of HIV infected and HIV affected children aged 2- 9 years and to evaluate the influence of clinical and environmental factors on their profile. The profiles of HIV infected and affected children in the preschool age (2- 5 years) and school age( 5 - 9 years) were also compared.
**Methods:** Fifty HIV infected, 25 HIV affected and 25 presumably unaffected 2-9 year old children were enrolled excluding children with known neurodevelopmental disorders. Parents were administered Developmental Profile (DP3), Vineland Adaptive Behavior Scale (VABS 2) and Child Behavior Checklist (CBCL) for assessing cognitive function, adaptive function and behavioral profile respectively. Primary outcomes included the number of children with significant cognitive or adaptive impairment or maladaptive behavior. Inter-group mean scores were compared with unpaired t test and correlation using regression analyses. Strength of the association between primary outcome variables and combinations of clinical and environmental variables was derived by Multiple Correlation Coefficient (R).
**Results:** Significant cognitive impairment was observed in 76% HIV infected, 64% HIV affected and 24% controls. Significant adaptive impairment was observed only in 24% HIV infected and 8% HIV affected children.Mean General Developmental Scores (GDS) and Mean Adaptive Composite scores (ABC) was significantly lower for HIV infected than HIV affected and controls. Maladaptive behavior was not found in any group.

| Primary Outcome Variable | HIV infected (n=50) (1) | HIV affected (n=25) (2) | controls (n=25) (3) | p value (1 vs 2) | p value (1 vs 3) | p value (2 vs 3) |
|---|---|---|---|---|---|---|
| GDS (MEAN±SD) | 59.2±16.9 | 70.1±13.4 | 77.3±13.4 | **0.007** | **0.0001** | **0.043** |
| ABC (MEAN±SD) | 75.2±8.9 | 82.4±9.1 | 85.3±7.3 | **0.005** | **0.0001** | 0.224 |
| T SCORES (MEAN)±SD) | 29.2±6.0 | 25.9±1.7 | 26.6±1.7 | **0.011** | **0.040** | 0.203 |

*[Table 1]*

Advanced stages of HIV infection (clinical stage T 3 and 4) were predictive of poor outcomes in adaptive function in HIV infected children.Higher socioeconomical class (class 2) was predictive of better outcomes in cognitive and adaptive function in HIV infected children. Strong associations were found between combined clinical and environmental covariates with cognitive and adaptive impairment in HIV infected children (R 0.81, 0.84 respectively).
**Conclusions:** A large proportion of HIV infected and HIV affected Indian pre-school and school aged children have significant cognitive and adaptive impairment. Global impairment among various domains of cognitive and adaptive was observed in HIV infected children.

## TUPEB103

### PREVALENCE OF HIV AND PRE-CERVICAL CANCER CO-MORBIDITY IN WOMEN UNDER 25 YEARS OF AGE COMPARED TO WOMEN OVER 25 YEARS OF AGE: LESSONS FROM ZAMBIA

Y. Mulenga[1], C. Makoane[2], M. Kasonde Kayama[1], F. Banda[3], J. Musonda[4], E. Graeber[5]
*[1]Project Concern International (PCI), Programs, Lusaka, Zambia, [2]Project Concern International, HIV/AIDS, Washington DC, United States, [3]Defence Force Medical Services, Health, Lusaka, Zambia, [4]Project Concern International (PCI), Management, Lusaka, Zambia, [5]Project Concern Inernational (PCI), Monitoring and Evaluation, Gaborone, Botswana*
*Presenting author email: ymulenga@pciglobal.org*

**Background:** Zambia has one of the highest HIV prevalence rates in Sub-Saharan Africa at 13%. The prevalence rate among women is 15% compared to men at 11%. Zambia also has the world's fourth highest cervical cancer incidence rate at 58.0 per 100,000. National cervical cancer guidelines recommend screening for women 25 to 59 years old. However in countries with generalized HIV epidemics like Zambia, the World Health Organization recommends screening HIV positive and sexually active young women and girls below age 25.

**Description:** Between March 2015 and November 2015, PCI implemented an integrated mobile HIV testing/ cervical cancer screening program in 19 ZDF sites (9 rural, 10 urban). Women 25 to 59 years old were primarily targeted while young women and girls below 25 years were incidentally enrolled. HIV Testing and Counseling (HTC) was offered by trained lay counselors; and women accessing HTC services were offered opt-out cervical cancer screening services. Trained nurse midwives screened women for cervical cancer using visual inspection with acetic acid (VIA). VIA positive women with small precancerous lesions were treated on-site using cryotherapy. Women with large lesions were referred to district hospitals for further management.
**Lessons learned:** Of 3,793 total women screened, 843 (22.2%) were below 25 years old (15 - 23 years, median age 18). For women under 25 years, 59 (6.9%) were HIV positive; 35 (4.1%) were VIA positive; and 8 (0.9%) were VIA and HIV positive. A total of 2,950 (77.8%) women were the primary target (25 years and above, median age 35). For women 25 to 59 years, 580 (19.7%) were HIV positive; 133 (4.5%) were VIA positive; and 43 (1.5%) were VIA positive and HIV positive.
**Conclusions/Next steps:** The high prevalence of lesions in young women mirrors prevalence in older women, indicating that sexually active women, regardless of age, should be targeted for cervical cancer screening and treatment. Although the HIV prevalence rate in older women was almost three times higher than in younger women, HIV/pre- cervical cancer co-morbidity rates indicate increased risk among the younger population in generalized epidemics, requiring further study for impact mitigation.

## OPPORTUNISTIC INFECTIONS IN INFANTS, CHILDREN, AND ADOLESCENTS

### TUPEB104

#### MORTALITY AND ASSOCIATED FACTORS IN ART-NAÏVE HIV-INFECTED CHILDREN WITH A SUSPICION OF TUBERCULOSIS

O. Marcy[1,2], M. Tejiokem[3], P. Msellati[4], H.K. Truong[5], B. Nacro[6], F. Ateba-Ndongo[7], V. Ung[8,9], B. Dim[2], L. Borand[2], C. Delacourt[10], S. Blanche[11]

*Presenting author email: oliviermarcy@gmail.com*

**Background:** Tuberculosis is a major opportunistic infection with specific diagnostic and treatment challenges in HIV-infected children. We studied mortality and its determinants in antiretroviral treatment (ART)-naïve HIV-infected children presenting a suspicion of tuberculosis.
**Methods:** From April 2011 to May 2014, HIV-infected children aged ≤13 years with a suspicion of tuberculosis were enrolled in pediatric HIV clinics in Burkina Faso, Cambodia, Cameroon, and Vietnam, and followed for 6 months in the ANRS 12229 PAANTHER cohort. After tuberculosis diagnostic procedures, ART and tuberculosis treatments were initiated following national recommendations. We assessed mortality rates and identified associated factors using Cox proportional hazard models.
**Results:** We enrolled 267 ART-naïve children in the cohort (138 (51.2%) male) with the following baseline characteristics [all median (IQR)]: age 6.2 (2.3 - 9.1) years, weight-for-age Z score -2.5
(-3.6 to -1.9), CD4% 9.0 (2.0 - 18.0), aspartate aminotransferase (AST) 48 (36 - 83) UI/L. During the study, 152 (56.9%) children started tuberculosis treatment after a median time of 7 (IQR: 5 - 11) days, and 216 (80.9%) initiated ART after a median time of 24.5 (14 - 41) days. Overall, 52 (19.5%) children died; 28 before and 24 after ART initiation. Mortality rates were 92.6 (95%CI 62.8 - 131.8) and 29.6 (95%CI 19.4 - 43.3) deaths per 100 Person-Years before and after ART initiation, respectively. In multivariate analysis, factors significantly associated with overall mortality were, as expected, an age
< 2 years [Hazard Ratio (HR) 3.30; 95%CI 1.21 - 8.98], CD4 < 10% (HR 2.39; 95%CI 1.13 - 5.04), culture-confirmed tuberculosis (HR 2.77; 95%CI 1.27 to 6.06), miliary radiographic patterns (HR 4.25; 95%CI 1.66 - 10.87), and more surprisingly, elevated baseline AST above 2.5 and 5xULN [(HR 3.68; 95%CI 1.49 - 9.11) and 3.78 (95%CI 1.23 - 11.60), respectively]. Young age, low CD4%, culture-confirmed tuberculosis, and miliary were associated with early mortality before ART; elevated AST was the only factor independently associated with mortality on ART.
**Conclusions:** Mortality remains high in the first 6 months following suspicion of tuberculosis in ART-naïve children, especially before ART introduction. Suspicion of tuberculosis should not postpone initiation of ART in children with very low CD4 count.

### TUPEB105

#### A CASE REPORT: IRIS-LIKE PRESENTATION OF BACILLIARY ANGIOMATOSIS IN A HIV-INFECTED CHILD IN THE SOUTHERN HIGHLANDS ZONE OF TANZANIA

J. Bacha[1,2], L. Campbell[1,2], N. El-Mallawany[3], C. Kovarik[4], G. Shutze[5], S. Shea[6]
*[1]Baylor International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine Children's Foundation - Tanzania, Mbeya, Tanzania, United Republic of, [3]Baylor College of Medicine, Texas Children's Cancer and Hematology Centers, Houston, United States, [4]Hospital of the University of Pennsylvania, Department of Dermatology, Philadelphia, United States, [5]Baylor College of Medicine, Houston, United States, [6]Baylor College of Medicine Children's Foundation - Tanzania, Baylor International Pediatric AIDS Initiative (BIPAI), Mbeya, Tanzania, United Republic of*
*Presenting author email: sshea@bcm.edu*

**Background:** Bacillary angiomatosis (BA) is an opportunistic gram-negative infection occuring primarily in immunocompromised individuals, though rarely seen in children, and often confused with Kaposi sarcoma (KS). Worsening of BA during immune reconstitution inflammatory syndrome (IRIS) after initiation of ART is not well described in children. We report a case of likely BA IRIS in a HIV-infected child.
**Methods:** Retrospective chart review. Full consent was obtained from patient and family.
**Results:** A 12 year old HIV-infected boy with severe malnutrition was referred to the Mbeya COE for treatment of widespread sores and fungating lesions. Seven months prior, he was diagnosed with HIV and started on ART, baseline CD4 of 76. His lesions began one month after ART initiation and progressively worsened. He had multiple admissions and courses of antibiotics without improvement prior to referral, and was referred for concern of possible KS.
The patient was admitted and skin biopsy done. A clinical diagnosis of BA was favored, and empiric treatment with doxycycline 100mg BD was started. Chemotherapy for KS was withheld. Imaging, sputa for geneXpert and smear, and chemistries all were normal. Viral load was undetectable. CBC showed severe anemia (Hb of 4.0) requiring blood transfusion. Biopsy results showed histology consistent with BA and bacilli seen with Warthin-Starry staining. Following doxycycline and malnutrition care, the patient made remarkable improvement of his lesions and overall condition.

*[Initial presentation and response to treatment of bacillary angiomatosis in HIV-infected child]*

**Conclusions:** We describe a case that supports the diagnosis of BA IRIS in a HIV-infected child that was successfully treated with doxycycline. While a systemic disease, BA frequently presents as lesions in cutaneous or subcutaneous tissues that can mimick KS - as in our patient - and clinicians must keep a high index of suspicion for BA in immunocompromised patients with unusual skin lesions not responding to standard treatments, particularly in the context of immune restoration.

## HIV-EXPOSED UNINFECTED CHILDREN (INCLUDING EFFECTS OF ART EXPOSURE DURING PREGNANCY)

Martinos Centre for Biomedical Imaging, Department of Radiology, Charlestown, United States, [5]Harvard University, Department of Radiology, Boston, United States, [6]New Jersey Institute of Technology, Department of Biomedical Engineering, Newark, United States, [7]African Institute for Mathematical Sciences, Muizenberg, South Africa, [8]National Institutes of Health, Scientific and Statistical Computing Core, Bethesda, United States*

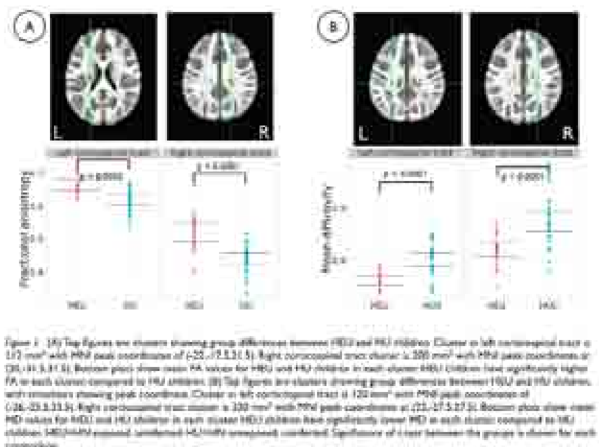
*Presenting author email: martha.j.holmes@gmail.com*

**Background:** A result of the high success of PMTCT programs in South Africa is a burgeoning population of HIV-exposed, uninfected (HEU) children. The long-term effects of exposure to ART/HIV in utero (and during breast feeding) are still relatively unknown, and multimodal magnetic resonance imaging (MRI) can help quantify the possible long-term effects of ART/HIV exposure on neurodevelopment.

We present significant group differences between measures of brain structure, function and metabolism in a cohort of HEU and HIV-unexposed, uninfected (HU) children at age 7.

**Methods:** Fifty-one 7-year-old children were scanned (23 Female; mean age ± sd: 7.2 ± 0.1; 9 Cape Coloured/42 Xhosa; 23 HEU/28 HU) in an on-going longitudinal study on a 3T Allegra Scanner (Siemens, Erlangen, Germany) in Cape Town, South Africa. HEU children were exposed to treatment for PMTCT.

The protocol included structural MRI, single voxel $^1$H magnetic resonance spectroscopy (MRS), diffusion tensor imaging (DTI), and resting state functional MRI (RS-FMRI). Specific exclusion criteria were applied to each modality to ensure quality data. Group comparisons between HEU and HU children were performed. Statistical analyses included gender and ethnicity confounds.



*[Comparison of DTI measures between HEU and HUU children at age 7 years]*

**Results:** Compared to HU children, we found that HEU children had significantly:

**(1)** Higher local gyrification indices (LGIs) ($p < 0.05$) in the left precuneus region,

**(2)** Higher mean choline levels ($p = 0.02$) and lower mean NAA/Creatine ratios ($p$=0.05) in the midfrontal gray matter (MFGM),

**(3)** Higher mean connectivity ($p < 0.05$) from seeds within the default mode, executive control, motor, salience networks, and

**(4)** Higher FA ($p < 0.0005$) and lower MD ($p < 0.0001$) in bilateral corticospinal tract clusters (figure 1).

**Conclusions:** Significant differences between HEU and HU children across all neuroimaging modalities suggest differences in maturation throughout the brain related to HIV/ART exposure - involving cortical folding, localized metabolism, numerous functional networks and white matter microstructure properties.

### INCREASED RISK OF MORBIDITY/MORTALITY AMONG FORMULA FED HIV-EXPOSED UNINFECTED INFANTS IN SOCIOECONOMICALLY CHALLENGED HOUSEHOLDS IN BOTSWANA: FINDINGS FROM THE MPEPU STUDY

K. Powis[1,2,3], S. Lockman[2,3,4], G. Ajibola[3], K. Bennett[5], M. Hughes[6], O. Batlang[3], K. Ramogothobeng[3], E. van Widenfelt[3], J. Makhema[3], M. Essex[2,3], R.L. Shapiro[2,3,7]

*[1]Massachusetts General Hospital, Departments of Internal Medicine and Pediatrics, Boston, United States, [2]Harvard TH Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [3]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [4]Brigham and Women's Hospital, Infectious Disease Division, Boston, United States, [5]Bennett Statistical Consulting Inc, Ballston Lake, United States, [6]Harvard TH Chan School of Public Health, Department of Biostatistics, Boston, United States, [7]Beth Israel Deaconess Medical Center, Infectious Diseases Department, Boston, United States*

*Presenting author email: kpowis@mgh.harvard.edu*

**Background:** A South African observational study, conducted when policy promoted HIV-infected maternal infant feeding choice based upon formula feeding acceptability, feasibility, affordability, sustainability, and safety, identified > 3-fold increased mortality risk among HIV-exposed formula fed infants in households without piped water, electricity, or gas for fuel, compared with breastfed infants. We sought to determine the applicability of these findings in Botswana, where the prevention of mother-to-child HIV transmission program promotes exclusive formula feeding for all HIV-exposed uninfected (HEU) infants.

**Methods:** Demographic and health outcomes data from the Mpepu study, a Botswana-based randomized double-blinded clinical trial investigating prophylactic cotrimoxazole as a means of reducing mortality among HEU infants, were used to quantify differences in the combined end point of hospitalizations and mortality between breastfed and formula fed HEU infants residing in households without piped water, electricity, or gas for a fuel source. Per Botswana guidelines, infant feeding was according to maternal choice, with free formula provided by the Botswana government for mothers choosing to formula feed.

**Results:** A total of 680 (21%) of 3,164 Mpepu enrolled infants resided in households without piped water, electricity or gas for fuel source, 552 (81%) formula fed and 128 (19%) breastfed. Formula fed infants experienced a higher prevalence of hospitalization or death in the first six months of life (10.0% versus 3.9%; p = 0.04). In multivariate analysis including infant feeding practice and randomized treatment, formula feeding was associated with increased odds of hospitalization or death in the first six months of life (aOR 2.73; 95% CI 1.07-6.96; p=0.04), but there was no benefit of Cotrimoxazole prophyalxis (aOR 0.97; 95% CI 0.57-1.65; p=0.91).

**Conclusions:** Formula fed HEU infants residing in socioeconomically challenged households in Botswana experienced significantly higher hospitalizations or mortality through 6 months, supporting the South African study's generalizability. Infants in our population were confirmed HIV-uninfected, and morbidity and mortality rates were low in the cohort as a whole, highlighting the excess risk associated with formula feeding even in regions of Africa where formula feeding may currently be considered a safe option.

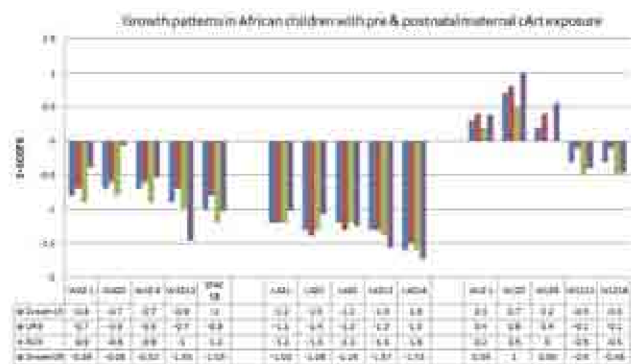
plementation with growth and health monitoring until 18 months. Data on growth parameters of children exposed to maternal pre/postnatal cART to 12 months are presented and compared to a cohort breastfed for 6 months.

**Methods:** Over a two year period, HIV-exposed infants were followed prospectively with weight and length measured and weight-for-age, height-for-age, and weight-for-height Z-scores (WAZ, LAZ; WLZ) calculated at various time points through the WHO Anthro software. Retention in the program was reinforced by peer to peer and health worker counselling. Statistical analysis was performed using IBM SPSS software.

**Results:** Growth assessment data was collected from 3907 children enrolled in Mozambique (n=2305) and Malawi (n=1602) from 01/2012 to 12/2013. The figure shows Z-scores for pediatric populations from 2015 and 2009 (breastfed for 12 and 6 months respectively) and 2015 data dichotomized according to rural (RUR) or urban (URB) environments from 1 to 18 months. The 2015 cohort had the best growth parameters especially at 12 and 18 months. Growth failure observed in the 2009 cohort at 6-12 months was greatly reduced in the 2015 cohort. Growth retardation in the 2015 rural cohort was significantly higher in comparison to the 2015 urban population. Binary logistic regression identified 3 independent predictors of malnutrition: WLZ < 3 z scores at 18 months: HIV+ status (HR: 5.5 p< 0.0001), rural environment (HR:2.3 p < 0.0001) and number of clinical events (HR:1.6 p< 0.003).



*[Z-scores over time]*

**Conclusions:** Provision of maternal cART pre and postnatally with 12 months of breastfeeding plus careful weaning practices and food supplementation favorably impact infant growth and development.

## ARV management strategies: children and adolescents cohort studies

#### Trends in global pediatric HIV programmatic capacity among sites of the International epidemiologic Databases to Evaluate AIDS (IeDEA) Consortium

R. Vreeman[1,2], M.L. Lindegren[3], C.W. Wester[3], M. Blevins[3], A.H. Sohn[4], M.-A. Davies[5], A. Edmonds[5], C. Quinn[3], S. Nwosu[3], K. Wools-Kaloustian[1,2], V. Leroy[6], C. McGowan[3], M.J. Vinikoor[7,8], International Epidemiologic Databases to Evaluate AIDS (IeDEA) Consortium

*[1]Indiana University, Pediatrics, Indanapolis, United States, [2]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [3]Vanderbilt University School of Medicine, Nashville, United States, [4]TREAT Asia/amfAR, Foundation for AIDS Research, Bangkok, Thailand, [5]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Department of Epidemiology, Chapel Hill, United States, [6]Inserm U 897, Bordeaux, France, [7]Centre for Infectious Disease Research, Lusaka, Zambia, [8]University of Alabama at Birmingham School of Medicine, Birmingham, United States*

*Presenting author email: kwools@iu.edu*

**Background:** Global pediatric HIV care sites push to expand access to care and implement recommended guidelines. We sought to describe trends in site capacity and comprehensiveness of services among global pediatric HIV care programs between 2009 and 2014.

**Methods:** In 2009, we assessed available services at sites caring for pediatric patients in 6 global regions of the International Epidemiologic Database to Evaluate AIDS (IeDEA) consortium. Between September 2014 and January 2015, we repeated this assessment, using a web-based survey across IeDEA regions. The surveys asked about facility characteristics and capacity to deliver WHO-recommended pediatric HIV prevention, care, and treatment services. We created a measure of comprehensiveness of available pediatric care services based on the WHO's current 9 categories of essential services. In the subset of sites with data from both 2009 and 2014, we evaluated trends in service delivery capacity.

**Results:** Clinical staff from 172 pediatric sites in 45 countries completed the 2014-2015 site survey. The available services in 2014 varied across regions and sites overall; only 40% of sites provided HIV counseling and testing, whereas 99% offered adherence counseling (Table 1). Overall, 35% of sites (n=61) offered comprehensive services (8-9 essential services out of 9), while 55% (n=94) offered 5-7 essential services and 10% (n=17) offered only 3-5. In the 2014 survey, the median comprehensiveness score across all of the sites was 7.0 (IQR 6.0-8.0), a significant increase from the median of 6.0 (IQR 4.2-6.0) in 2009 ($p$< 0.001), and the magnitude of change varied by region ($p$< 0.001). The two WHO essential services with most varied provision across global regions were 1) HIV counseling and testing and 2) both CD4 and HIV viral load testing (Table 1).

| Essential Services | % Offered, 2009 (N=38*) | % Offered, 2014 (N=38*) | % Offered, 2014 (N=172) | Asia Pacific (N=16), 2014 | CCASAnet (N=7), 2014 | Central Africa (N=7), 2014 | East Africa (N=34), 2014 | Southern Africa (N=86), 2014 | West Africa (N=12), 2014 |
|---|---|---|---|---|---|---|---|---|---|
| ART Adherence | 76% | 100% | 99% | 16 (100%) | 6 (86%) | 17 (100%) | 34 (100%) | 86 (100%) | 12 (100%) |
| Nutrition | 11% | 68% | 56% | 12 (75%) | 4 (57%) | 4 (24%) | 25 (74%) | 45 (52%) | 7 (58%) |
| PMTCT | 87% | 97% | 96% | 13 (81%) | 7 (100%) | 17 (100%) | 34 (100%) | 85 (99%) | 9 (75%) |
| CD4 and HIV Viral Load Testing | 3% | 53% | 51% | 11 (69%) | 4(57%) | 12 (71%) | 17 (50%) | 34 (40%) | 9 (75%) |
| TB Screening | 82% | 84% | 87% | 16 (100%) | 7 (100%) | 12 (71%) | 32 (94%) | 76 (88%) | 7 (58%) |
| HIV Counseling and Testing | 18% | 42% | 40% | 11 (69%) | 6 (86%) | 4 (24%) | 16 (47%) | 25 (29%) | 6 (50%) |
| Co-trimoxazole | 76% | 92% | 97% | 16 | 7 (100%) | 17 | 31 | 83 (97%) | 12 |
| Immunizations | 68% | 58% | 73% | 13 (81%) | 7 (100%) | 12 (71%) | 24 (71%) | 64 (74%) | 5 (42%) |
| Outreach | 68% | 95% | 95% | 14 (88%) | 4 (57%) | 15 (88%) | 34 (100%) | 86 (100%) | 11 (92%) |

*[Distribution of WHO Essential Services for Pediatric HIV Care and Treatment in 2009 and 2014, and by Global IeDEA Region]*

**Conclusions:** This global survey demonstrates significant gains in the comprehensiveness of services available for HIV-infected children worldwide, while identifying gaps to target resources.

Chan School of Public Health, Boston, United States, [6]Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom, [7]Emma Children's Hospital, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [8]CESP, INSERM U 1018, Paris, France, [9]University of Padua, Padua, Italy, [10]PENTA Foundation, Padua, Italy*

*Presenting author email: jeannie.collins@ucl.ac.uk*

**Background:** There are scarce data on poor immune response (PIR) despite viral suppression (VS) on ART in children. We assessed PIR prevalence, associated factors and clinical outcomes in EPPICC.

**Methods:** Children aged< 18-years at ART start, with ≥1 year follow-up, ≥1 viral load (VL) and CD4 measurements were eligible. VS was defined as VL≤400 copies/mL within 12-months of ART initiation
(< 18-months for infants) and sustained VL≤400 c/mL for ≥1 year (allowing unconfirmed rebound < 10,000 c/mL). PIR was defined as WHO 'advanced' or 'severe' immunological stage (CD4%< 30 for age< 12-months, CD4%< 25 for 12-35 months, CD4%< 20 for 35-59 months; CD4%< 15 or CD4< 350 cells/mm$^3$ for ≥5-years). Follow-up was censored at confirmed VL>400c/mL, unconfirmed VL≥10,000c/mL or VL measurements gap of ≥15-months. Factors associated with PIR were explored using logistic regression. Rates of clinical events (death/CDC C) during VS were calculated by time-updated WHO immunological stage.

**Results:** Of 3,510 children starting ART, 2210(63%) had VS for ≥1 year: 47% male, 92% perinatally-infected. At ART initiation, median[IQR] age was 6.3yrs[2.1,10.4], CD4% 16% [8,24], 15% and 55% were WHO advanced and severe immunologi-

cal stage, respectively. PIR was observed in 13%(248/1863), 7%(102/1437) and 4%(50/1155) of patients at 1-, 2- and 3-years of sustained VS. PIR was strongly associated with older age and worse immunological stage at ART start (Table). Among patients with VS for ≥1-year, there were 4 deaths and 50 CDC C events (2 and 15 among PIRs, respectively). The rate of clinical events was 1.94(95%CI 1.20, 3.12) per 100 person-years among PIRs versus 0.39(0.27,0.56) among responders (WHO immunogical stage "none"), p< 0.0001.
**Conclusions:** PIR despite VS was relatively rare in children but was associated with significantly increased risk of AIDS/death as compared to immune-responders. Predictors of PIR include older age and lower CD4 at ART start, supporting recommendations for immediate ART in all children.

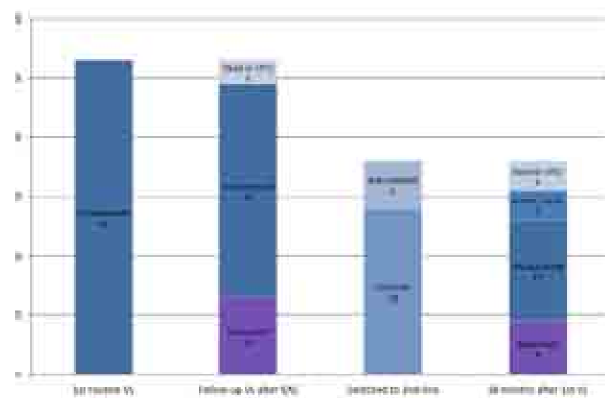
### THE TREATMENT CASCADE OF CHILDREN WITH UNSUPPRESSED VIRAL LOAD: A REALITY CHECK IN RURAL LESOTHO, SOUTHERN AFRICA

T.I. Lejone[1], I. Ringera[1], M.A.T. Klaas[2], J. Ehmer[3], K. Pfeiffer[3], C. Fritz[4], T. Klimkait[5], N.D. Labhardt[6,7]
*[1]SolidarMed, Swiss Organization for Health in Africa, Butha-Buthe, Lesotho, [2]Ministry of Health of Lesotho, Laboratory Services Butha-Buthe, Butha-Buthe, Lesotho, [3]SolidarMed, Swiss Organization for Health in Africa, Lucerne, Switzerland, [4]SolidarMed, Swiss Organization for Health in Africa, Maseru, Lesotho, [5]Department of Biomedicine - Haus Petersplatz, Basel, Switzerland, [6]Swiss Tropical and Public Health Institute, Medical Services and Diagnostics, Basel, Switzerland, [7]University of Basel, Basel, Switzerland*
*Presenting author email: t.lejone@solidarmed.ch*

**Background:** Viral load (VL) monitoring for children on anti-retroviral therapy (ART) allows early recognition and management of treatment failure. However, there is currently few data on outcomes of children failing first-line ART in resource-limited settings. This registered prospective observational study (CART-1 study; clinical trials-ID: NCT02126696) assessed clinical and virological outcomes of children with unsuppressed VL in 10 rural, nurse-led clinics in Lesotho, Southern Africa.
**Methods:** Children < 16 years, on first-line ART≥6 months with unsuppressed VL (≥100copies/mL) at first measurement in May/June 2014 were included. As per guidelines children with unsuppressed VL received enhanced adherence counselling (EAC) and a follow-up VL after three months. Those with sustained unsuppressed VL were considered eligible for switch to second-line. In November/December 2015 (18 months later) their outcomes were assessed.
**Results:** Of 191 children receiving a first-time VL, 53 (28%) had unsuppressed viremia. The care-cascade for these 53 children is displayed in the figure. 49 (92%) received a follow-up VL 3 months after EAC. At this follow-up VL, 36 (73%) remained unsuppressed, 28 (78%) of these 36 were switched to second-line. Reasons for not switching were: Loss to follow-up or procedural errors at health facilities. Of the 36 children eligible for second-line, 9 (25%) were switched, retained, and virally suppressed at 18 months of follow-up. Socio-economic characteristics (age, sex, orphanhood, household-wealth, self-reported drug-adherence) were not associated with outcomes after the first measurement of unsuppressed VL.



*[Cascade of care for children with a first unsuppressed viral load (≥100copies/mL). LTFU: Lost to follow-up]*

**Conclusions:** Among 36 children with sustained virologic failure on first-line ART only 9 (25%) had achieved viral suppression through switch to second-line 18 months after the first measurement of an unsuppressed VL. These figures reflect the real-life outcomes of children with unsuppressed viremia under first-line ART in rural resource-limited settings. Interventions targeted to children and their caregivers are needed for improving effectiveness of roll out programs for VL-monitoring in resource-limited settings.

## TUPEB112

### CAN CHILDREN WITH HIV REACH THE 90-90-90 GOALS? VIRAL SUPPRESSION IN A PEDIATRIC PATIENT POPULATION IN WESTERN KENYA

B. Patterson[1], J. Kadima[2], M. Mburu[2], C. Blat[3], E. Bukusi[2], C. Cohen[3], L. Abuogi[4]
*[1]University of Colorado School of Medicine, Aurora, United States, [2]Family AIDS Care and Education Services (FACES), Research Care and Training Program (RCTP), Centre for Microbiology Research (CMR), Kenya Medical Research Institute (KEMRI), Kisumu, Kenya, [3]University of California, San Francisco, United States, [4]University of Colorado Denver, Department of Pediatrics, Aurora, United States*

**Background:** BackgroundRoutine viral load monitoring is critical in measuring treatment efficacy and achieving the UNAIDS 90-90-90 goals. In this study, we investigated potential risk factors associated with failure to reach virologic suppression in a pediatric patient population in western Kenya.
**Methods:** MethodsIn November 2013, viral load (VL) testing 6 months after initiation of antiretroviral therapy (ART) and yearly thereafter was rolled out in clinics throughout western Kenya. This nested case-control study was conducted among HIV-infected children < 15 years old who underwent routine VL testing June 2014-May 2015. A random sample of 299 children with approximately 1 case [VL ≥1000 copies (cp) per milliliter (ml)] per every 2 controls (VL < 1000 cp/ml) was chosen from five Family AIDS Care & Education Services (FACES)-supported facilities. Chart abstraction was performed to determine demographic and clinical factors associated with failure to suppress. Logistic regression analysis was used to assess factors associated with failure to suppress VL.
**Results:** ResultsAmong all children undergoing routine VL testing, 63% (748/1190) were virologically suppressed. Of the 98 unsuppressed cases and 201 controls, the majority (72%) were between ages 3 and 10 years old at time of VL testing. Baseline WHO stage and CD4, and time since ART initiation were not associated with failure to suppress. In multivariable analysis, unsuppressed children were more likely to be male (adjusted Odds Ratio (aOR)=2.1, 95% Confidence Interval (CI): 1.2-3.5) and be on lopinavir as a second line regimen (aOR=5.3, 95% CI: 2.4-11.8) (Table 1). Additionally, children with a history of tuberculosis (TB) were more likely to suppress than those without TB (aOR=0.4, 95% CI: 0.2-0.9).
**Conclusions:** ConclusionsApproximately a third of children undergoing routine VL testing failed to suppress. Traditional risk factors for pediatric treatment failure including baseline CD4 and clinical stage were not shown to have a significant effect on VL, highlighting the importance of routine VL testing to evaluate treatment efficacy. Reasons for gender differences in suppression and surprisingly higher rates of VL suppression amongst children with history of TB require further exploration. Additional effort will be required in order to reach the final "90" among children in Kenya.

| Measure | VL ≥1000 cp/ml (case) n (%) or median (IQR) | VL <1000 cp/ml (control) n (%) or median (IQR | p-value | | OR (95% CI) | p-value | aOR (95% CI)1 | p-value |

## BEHAVIOURAL HEALTH OUTCOMES IN CHILDREN AND ADOLESCENTS (INCLUDING SEXUAL RISKS, SUBSTANCE USE)

### TUPEB113

### TABLET-BASED RESOURCES FOR DISCLOSURE COUNSELING FOR HIV-INFECTED ADOLESCENTS AND THEIR FAMILIES IN KENYA: A PILOT STUDY OF PERSPECTIVES FROM PROVIDERS

M. McHenry[1,2], E. Apondi[2,3], C. Mcateer[1,2], W. Nyandiko[2,3], L. Fischer[4], R. Ombitsa[2], J. Aluoch[2], M. Scanlon[1,2], R. Vreeman[1,2,3]

*[1]Indiana University School of Medicine, Children's Health Services Research, Indianapolis, United States, [2]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [3]Moi University, College of Health Sciences, School of Medicine, Department of Child Health and Paediatrics, Eldoret, Kenya, [4]Indiana University School of Medicine, Indianapolis, United States*

*Presenting author email: rvreeman@iu.edu*

**Background:** Overwhelmed, under-trained medical staff working in resource-limited settings need efficient resources to help support families during the process of HIV disclosure to children. This study evaluated providers' perceptions of using tablet computers for disclosure-related counseling with HIV-infected children and their caregivers in western Kenya.

**Methods:** This study used a mixed-methods design at three large, rural HIV clinics in western Kenya (Bumala, Busia, and Port Victoria) within Academic Model Providing Access to Healthcare (AMPATH). Healthcare providers involved with pediatric disclosure were recruited. Initial interviews focused on understanding current disclosure practices and barriers. Tablets containing disclosure-related resources were distributed. Resources included short narrative videos created in this context to highlight issues relevant to child HIV disclosure. Self-reported use was tracked with five monthly surveys, followed by repeat interviews. Interviews were transcribed and coded using a grounded theory approach to identify key themes. Survey data were analyzed using Wilcoxon signed ranks test and paired t-tests.

**Results:** 21 healthcare providers participated (8 clinical officers, 5 nurses, 8 social support staff). Most believed caregivers should disclose their children's status to them, with healthcare providers offering encouragement and answering children's questions. Major perceived barriers for caregivers to disclose were lack of parental HIV knowledge and stigma. Surveys indicated tablets were used during 75% or more of clinic encounters by 67% (14/21) of providers one month after tablet distribution, and 85% (18/21) at the end of the study. Provider comfort with disclosure increased significantly during the study (8.29 vs 9.33, 95%CI: -2.018 to -0.077). At follow-up, all (n=21) providers reported tablets improved clinic disclosure process. Many (n=16) reported child participation and adherence improved and children increasingly attended clinic specifically to watch tablet disclosure videos. Providers reported caregivers and children began initiating dialogue about critical issues such as medication adherence after watching the disclosure videos. Additionally, all (n=21) reported reviewing materials during their free time, in particular outside of work, to increase their own knowledge and comfort with disclosure. No technical issues were reported.

**Conclusions:** Tablet computers with resources for disclosure are an acceptable and potentially effective resource to help providers support families through the disclosure process.

### TUPEB114

### ACHIEVING FIRST 90 (90:90:90) GOAL IN ADOLESCENT/YOUNG ADULTS! ADOLESCENT PEER-LED COMMUNITY OUTREACH AND KNOWLEDGE DISSEMINATION: THE WAY TO GO

M. Akolo[1], J. Kimani[2], L. Gelmon[2]

*[1]Kenya AIDS Control Project, Clinic, Nairobi, Kenya, [2]University of Manitoba, UNITID, Nairobi, Kenya*

*Presenting author email: molly_akolo@yahoo.com*

**Background:** The University of Nairobi/Manitoba STI/HIV research center started in 1986, enrolling and following up mothers and their newborn babies from Pumwani Maternity Hospital. HIV testing, care and treatment was one of the services offered. In 2006 the Pumwani Clinic opened up to the general population and offers HIV prevention, care and treatment to all eligible. Recently a gap of not reaching many adolescents was identified and measures were put in place to collect baseline data on HIV prevention knowledge, attitude and practice among the adolescents from the community.

**Methods:** A crossectional KAP study that utilized mixed methods of data collection was carried out for three months on adolescents/ young adults aged between 15-24 years. Ten peer adolescents were trained and sent into the community to refer their peers to the clinic. HIV testing was offered and data collected on HIV prevention knowledge, attitude and practice.

**Results:** 1107 adolescents/young adults were reached 43.9 %( 486) were male and 56.1 %( 621) female. 13.0% (144) were married. Only 49.7% (550) had tested for HIV before while 100% reported being sexually active. HIV prevalence in this group was 5.9 %( 65) which is higher than the Kenyan national average. 25% (277) had their sex debut between ages 12-14 years, 60.7 %( 672) at age 15-17 years while 14.3 %( 158) at age 18-19 years. 46.5 %( 515) reported condom use of which consistent condom use was 54.3 %( 280). Correct condom use demonstration was achieved by 3.4% (38). Only 19.1% (199) of the HIV negative had knowledge on PrEP, while 68.2 %( 755) were willing to use PrEP after being taught on PrEP. 11.7% (122) had knowledge on PEP while 98% (1084) were willing to use PEP after sensitization.

**Conclusions:** Despite a high level of early onset of sexual activity in this adolescent population, the HIV testing rate, PEP and PrEP knowledge is quite low, with an alarmingly low level of basic knowledge about condom use. Use of peer led initiative in reaching out to them may reduce the HIV testing gap and enhance HIV prevention knowledge hence, achieving the first 90 goal.

### TUPEB115

### SIMILAR LEVELS OF SEXUAL RISK BEHAVIOUR AMONG PERINATALLY HIV-INFECTED AND HIV-AFFECTED ADOLESCENTS, AND THE GENERAL POPULATION, IN ENGLAND

M. Le Prevost[1], K. Sturgeon[1], C. Foster[2], F. Parrott[1], E. Jungmann[3], K. Rowson[1], D. Gibb[1], A. Judd[1], Adolescents and Adults Living with Perinatal HIV (AALPHI) Steering Committee

*[1]University College London (UCL), MRC Clinical Trials Unit, London, United Kingdom, [2]Imperial College Healthcare NHS Trust, London, United Kingdom, [3]Central and North West London NHS Foundation Trust, London, United Kingdom*

*Presenting author email: m.leprevost@ucl.ac.uk*

**Background:** Perinatally HIV-infected (PHIV+) adolescents are surviving into adulthood, and gaining insight into sexual behaviour and the prevalence and predictors of HIV transmission is important. Previous studies report PHIV+ adolescents having less sex than their HIV-negative (HIV-) peers. Here we report findings for PHIV+ and HIV- youth in England.

**Methods:** 296 PHIV+ aged 13-21 years and 96 HIV- affected (45 siblings of PHIV+) adolescents aged 13-23 years were recruited to the AALPHI cohort in 2013-15. Computer-assisted self-interview questionnaires collected data on sexual activity (including type of sex, number of partners in last year and condom use), alcohol and recreational drug use. NPZ-6 scores were calculated for neurocognitive function, and IDACI scores measured household deprivation. T-tests compared means, and $\chi^2$ proportions; logistic regression examined predictors of ever having sex.

**Results:** 120(41%) PHIV+ and 31(32%) HIV- were male, 254(86%) and 70(73%) were black, median age 16[IQR 15,18] and 16[14,18] years respectively. 77(26%) PHIV+ had a previous CDC C diagnosis. 237(80%) PHIV+ and 68(71%) HIV- were in full-time

education, for 101(36%) and 21(23%) one/both parents had died, 122(42%) and 43(46%) had ever drunk alcohol and 43(15%) and 26(29%) had ever taken recreational drugs.
90(30%) PHIV+ and 37(38%) HIV- had ever had sex; median number of partners in the last year was 3[1,6] and 4[1,6] respectively. 61(68%) PHIV+ and 14(38%) HIV- reported always using condoms (p=0.005). Multivariable analysis (Table) identified older age, male sex, ever had alcohol and/or drugs and higher deprivation score, with ever having sex, but not HIV status.

| Variable | | Adjusted Odds Ratio (95% Confidence Interval) | P value |
|---|---|---|---|
| HIV status (ref: HIV-) | PHIV+ no CDC C | 1.05 (0.48, 2.28) | |
| | PHIV+ with CDC C | 1.09 (0.43, 2.75) | 0.994 |
| Age at interview | Per year increase | 1.46 (1.27, 1.68) | <0.001 |
| Sex (ref: Male) | Female | 0.50 (0.27, 0.92) | 0.027 |
| Ever had alcohol (ref: No) | Yes | 2.68 (1.36, 5.28) | 0.004 |
| Ever taken drugs (ref: No) | Yes | 3.54 (1.63, 7.69) | 0.001 |
| Household deprivation | Per 10 point increase | 1.18 (1.00, 1.41) | 0.053 |

*[Table: Multivariable predictors of ever having sex]*

**Conclusions:** Levels of sexual activity were similar among PHIV+ and HIV- and comparable to national normative data (Natsal-3). Levels of reported condom use were significantly higher in PHIV+ than HIV-, contrary to previous research suggesting higher risky sexual behaviour in PHIV+; findings underline the need for increased sexual health education for all adolescents.

## MENTAL HEALTH AND NEURO-COGNITION IN CHILDREN AND ADOLESCENTS

### TUPEB116

### A DIFFUSION TENSOR IMAGING AND NEUROCOGNITIVE STUDY OF ART-NAÏVE AND ART-TREATED CHILDREN IN CAPE TOWN

J. Hoare[1], N. Phillips[1], J. Fouche[1], K. Donald[2], K. Thomas[3], D. Stein[1]
*[1]University of Cape Town, Department of Psychiatry, Groote Schuur Hospital, Cape Town, South Africa, [2]University of Cape Town, Pediatrics, Cape Town, South Africa, [3]University of Cape Town, Psychology, Cape Town, South Africa*
*Presenting author email: hoare.jax@googlemail.com*

**Background:** There are still no diagnostic criteria for a spectrum of neurocognitive disorders (ND) secondary to HIV infection for children.
**Methods:** A cross-sectional clinical cohort study was initiated in Cape Town, in which 120 participants, including a HIV negative healthy control group for comparison, completed clinical and neurocognitive assessments. HIV infected children were either stable on antiretroviral treatment (ART) for a minimum of 6 months or ART naïve. Neuroimaging was completed on 105 children in the cohort study. We compared 75 children vertically infected with HIV aged 6 to 16 years, including both children on antiretroviral therapy (ART) and ART-naïve, with 30 matched controls using diffusion tensor imaging (DTI) measures. We then used the detailed neurocognitive battery; an assessment of adaptive functioning and the HIV associated neurocognitive disorders (HAND) for diagnosing ND to establish whether this system designed for adults could detect a spectrum of ND in HIV infected children.
**Results:** When comparing HIV-ve children to HIV+ve children DTI found damaged neuronal microstructure in the HIV+ve children. Significant associations were found between failing first line ART regimen, socio-demographic factors, nutritional-hematological status, HIV-relevant clinical variables, cognitive functioning and white matter integrity in children stable on ART. Children with a clinical diagnosis of encephalopathy (HIVE) had greater white matter damage when compared ART treated children without encephalopathy. DTI also found significant myelin loss in ART naïve children when compared with ART treated children. Using the criteria for HAND we found that 45.35% of the HIV infected children had a ND. ART naïve slow progressors, who receive limited attention from heath care services, as they are thought to be 'well', were found to have neurocognitive impairment and white matter microstructural damage. HIV infected children were also more likely to have impaired competence in various domains of functioning.
**Conclusions:** Our findings suggest that children on ART remain at risk for developing CNS disease, and that this risk extends to physically well ARV naïve slow progressors. The HAND criteria were able to identify children with functional cognitive impairments who don't fit criteria for HIVE and would therefore not have been identified otherwise.

### TUPEB117

### NEUROPSYCHOLOGICAL PERFORMANCE OF HIV-INFECTED AND UNINFECTED AFRICAN CHILDREN

M. Boivin[1], M. Chernoff[2], J. Lindsey[2], B. Zimmer[3], B. Laughton[4], C. Joyce[5], K. McCarthy[6], E.P. Browers[7], P. Jean-Philippe[8], S. Lee[9], J. Coatzee[4], L. Barlow-Mosha[10], A. Violari[5], P. Palumbo[11]

*Presenting author email: boivin@msu.edu*

**Background:** HIV-infected (HIV) children are at neuropsychological risk, but few studies have evaluated this at multiple sites in resource-poor settings. We compared neuropsychological outcomes at enrollment (> 5 yrs age) among HIV, HIV-uninfected perinatally-exposed (HEU), and HIV unexposed (HU) children at 6 sub-Saharan sites with language and cultural differences.
**Methods:** IMPAACT P1060 compared Nevirapine (NVP) versus Lopinavir/Ritonavir (LPVr)-initiated ART in HIV-infected children 6 to 35 months of age. P1104s enrolled these children at 5-11 years of age and evaluates their neuropsychological performance at 3 time points over 2 years, compared to age-matched HEU and HU controls.
Evaluation tools include the KABC-II cognitive ability, TOVA attention/impulsivity, BOT-2 motor proficiency tests, and parental BRIEF executive function questionnaires. Cohorts were compared using GEE least-squares means adjusted for site, child age and gender, and personal and social characteristics for child and caregiver. Exploratory HIV treatment-arm comparisons were made using Wilcoxon rank-sum tests.
**Results:** 611 (246 HIV, 183 HEeU, 182 HU) of the 615 enrolled at 6 sites (South Africa [3], Zimbabwe, Malawi, Uganda) were eligible for analysis. Mean age was 7.2 years, 48% male, 69% in school. 94% of caregivers were biological mothers, 32% had completed high school, 22% received social grants, 38% lived in urban areas, 29% judged family income as sufficient.
Unadjusted and adjusted comparisons were consistent. The HIV cohort performed significantly worse than HEU and HU cohorts on KABC-II, TOVA, BOT-2 overall performance ($P$< 0.05), but not on the BRIEF. HU and HEU cohorts were comparable.
Associations between test scores and caregiver socio-economic indicators as well as child school status, development and disability scores were observed. BRIEF scores were worse for children whose caregivers scored higher on depression and anxiety.
In the HIV cohort, the NVP cohort had lower median KABC-II Nonverbal Index scores (by 3 points, $P$=0.05) and BOT-2 standardized scores (by 1.5 points, $P$=0.03) than the LPVr cohort (unadjusted intent-to-treat).
**Conclusions:** Significant cognitive deficits were documented for the HIV cohort across sites. Earlier HIV treatment, neuropsychological monitoring and rehabilitative interventions are needed. Testing for 2 more years will help evaluate whether ongoing effects of HIV infection and exposure will affect the developmental trajectory.

### TUPEB118

### NEUROCOGNITIVE DIFFERENCES BY HIV-1 SUBTYPE A IN PRE-SCHOOL CHILDREN LIVING WITH HIV IN TORORO, UGANDA

H. Ruiseñor-Escudero[1], A. Sikorskii[2], I. Familiar[1], C. Ziemniack[3], D. Persaud[3], N. Nakasujja[4], R. Opoka[4], M. Boivin[1]
*[1]Michigan State University, Psychiatry, East Lansing, United States, [2]Michigan State University, East Lansing, United States, [3]Johns Hopkins School of Medicine, Baltimore, United States, [4]Makerere University, Kampala, Uganda*
*Presenting author email: hruiseno@jhsph.edu*

**Background:** In Uganda HIV-1 subtype A is the predominant clade, followed by subtype D. The effects of HIV-1 subtype on children's neurocognitive development are still unclear. We aimed to evaluate neurodevelopmental and neurocognitive differences by HIV-1 subtype among preschool-age Ugandan children.

**Methods:** One hundred and ten HIV infected Ugandan children ages 1.8 -4.9 years old (mean=3.2 yrs) were assessed for neurocognitive development using the Mullen Scales of Early Learning (MSEL), the Color Object Association Test (COAT) and the Early Childhood Vigilance Test (ECVT). Using a previously published PCR-based multi-region assay sequencing 390 bp of p24 GAG gene and 324 bp of gp41 ENV gene, subtype was defined by phylogenetic analyses with subtype references. General linear models were used to relate MSEL, COAT, and ECVT to socio-demographic characteristics, weight-for age z-score (WAZ), socio-economic status, quality of home environment, antiretroviral treatment (ARV) status, and HIV-1 subtype.
**Results:** HIV-1 subtype was determined in 110 children. Sixty eight (61.8%) were subtype A or unconfirmed subtype A (AU) (A|AU) and 42 (38.2%) were classified as non-A|AU. Children with HIV-1 subtype A|AU were comparable to non-A|AU in demographics, CD $4^+$ and CD $8^+$ cell count %, and viral load. After adjusting for covariates, children infected with subtype A|AU performed consistently better when compared to non-A|AU in three MSEL scales; Composite Score (Least Squares Mean (LSM) A|AU=76.60 vs. LSM non-A|AU=69.18, p=0.03), Fine Motor score (LSM A|AU=36.50 vs. LSM non-A|AU=31.37, p=0.04), and Receptive Language score (LSM A|AU=40.0 vs. LSM non-A|AU=35.77, p=0.03). In addition, being on ARV treatment was associated with worse scores in five of the six scales of the MSEL and in the Total Recall score of the COAT. Negative association of these outcomes with ARV treatment was also present among A|AU children.
**Conclusions:** Contrary to earlier findings with older ARV-naïve children, A|AU preschool children better in standardized neurodevelopmental tests (SNT) compared to those infected by other HIV-1 subtypes. Our findings suggest that HIV subtype may be an important consideration in pediatric HIV treatment strategies with ARVs.

## TUPEB119

### MENTAL HEALTH AND VIRAL SUPPRESSION IN A COHORT OF ADOLESCENTS LIVING WITH HIV IN JOHANNESBURG, SOUTH AFRICA

N. West[1,2], S. Schwartz[1], C. Hanrahan[1], P. Goliath-Soyizwaphi[2], J. Nel[3], H. France[2], J. Bassett[2], S. Bernhardt[2], J. Steingo[2], L. Mutunga[2], A. Van Rie[4,5]
*[1]Johns Hopkins School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Witkoppen Health and Welfare Centre, Johannesburg, South Africa, [3]Helen Joseph Hospital, Department of Infectious Diseases, Johannesburg, South Africa, [4]University of Antwerp, Antwerp, Belgium, [5]University of North Carolina at Chapel Hill - Gillings School of Global Public Health, Department of Epidemiology, Chapel Hill, United States*
*Presenting author email: nwest7@jhu.edu*

**Background:** A growing number of adolescents living with HIV are engaged in clinical care, especially in Africa. Little is known about their mental health and its association with viral suppression.
**Methods:** We conducted a baseline analysis from a prospective cohort of adolescents (ages 9-19) living with HIV and receiving care at a primary care clinic (Witkoppen Health and Welfare Center) in Johannesburg, South Africa. Mental health screens for depression were performed using the Children's Depression Inventory-Short (CDI-S10), anxiety using the Revised Manifest Anxiety Scale (RCMAS), and post-traumatic stress using the Child PTSD checklist. Clinical charts were reviewed to collect relevant demographic, clinical, and laboratory data. Multivariate logistic regression was used to identify factors associated with viral suppression (defined as < 50 copies/mL) in adolescents on anti-retroviral therapy (ART) for >90 days.
**Results:** Between June 2013 and November 2015, 258 adolescents were enrolled. Median age was 11 (range 9-19), 52% were female, and 72% had a deceased parent. Less than half (45%) were fully aware of their HIV status. Almost one-third (29%) reported an event causing post-traumatic stress. Few (7%) met the criteria for depression (CDI-S10 score ≥7), and 6% screened positive for anxiety (RCMAS score ≥10). Adolescents reporting post-traumatic stress had higher rates of anxiety (13% vs. 4%, p=0.011) and depression (14% vs. 4%, p=0.004). Among 191 adolescents on ART with viral load data, 46% were virally suppressed. In multivariate analysis, adolescents were less likely to achieve viral suppression if they reported post-traumatic stress (adjusted OR 0.43, 95% CI 0.18-1.01, p=0.053) or had full disclosure of their HIV status (OR 0.48, 95% CI 0.20-1.15, p=0.101).
**Conclusions:** This baseline analysis showed that post-traumatic stress occurs frequently in adolescents living with HIV and is associated with poor viral suppression. Furthermore, though the majority of adolescents screened did not meet the criteria for anxiety or depression, rates of both were higher among adolescents who reported post-traumatic stress. Findings suggest that attention to post-traumatic stress is warranted in adolescents living with HIV.

## TUPEB120

### CROSS-CULTURAL ASSESSMENT OF HIV-ASSOCIATED NEUROCOGNITIVE IMPAIRMENT USING THE KAUFMAN ASSESSMENT BATTERY FOR CHILDREN: A SYSTEMATIC REVIEW

K.S. van Wyhe[1,2], T. van de Water[2,3], M.J. Boivin[4,5], M.F. Cotton[2], K.G.F. Thomas[1],
The Applied Cognitive Science and Experimental Neuropsychology Team (ACSENT); Family Clinical Research Unit (FAM-CRU)
*[1]University of Cape Town, Psychology, Cape Town, South Africa, [2]Stellenbosch University, Paediatrics and Child Health, Cape Town, South Africa, [3]Stellenbosch University, Department of Psychiatry, Cape Town, South Africa, [4]Michigan State University, Psychiatry and of Neurology & Ophthalmology, East Lansing, United States, [5]University of Michigan, Psychiatry, Ann Arbor, United States*
*Presenting author email: vwykay001@myuct.ac.za*

**Background:** Despite improved efficacy of, and access to, combination antiretroviral therapy (cART), HIV-associated neurocognitive impairments (HANI) remain prevalent. Neuropsychological tests that detect HANI in children can help clinicians formulate treatment plans. The Kaufman Assessment Battery for Children (KABC), although developed and standardized in the United States, is used frequently in many different cultures and countries to assess pediatric performance within specific cognitive domains. The purpose was to investigate the cross-cultural utility of the original KABC, and its 2nd edition (KABC-II), in identifying HANI in children.
**Methods:** Relevant keywords and MeSH terms were entered into the PubMed, PsycInfo, EBSCOHost, ProQuest, and Scopus databases, with search limits set from 1983-2015. Two independent reviewers evaluated the retrieved abstracts and manuscripts. Studies eligible for inclusion in the review were those that
(a) used the KABC/KABC-II to assess cognitive function in children aged 2-18 years,
(b) featured a definition of HANI (e.g., >2SD below the mean),
(c) compared the performance of HIV+ and HIV- groups, and
(d) used a sample excluded from US census on which the instruments were normed.
The reviewers evaluated the methodological quality of selected studies independently.
**Results:** Eight studies comprised the sample of the systematic review. All except one (a UK-based study) were conducted in Africa. Study samples included cART-naïve or clinically stable cART-treated children. All studies reported some form of cognitive impairment in HIV-infected children. Five reported significant between-group differences on KABC/KABC-II subtests tapping the cognitive domain of simultaneous processing (e.g., the Triangles, Rover, and Block Counting subtests);
4 reported the same for sequential processing; 3 did so for learning; and 3 did so for a mental processing index. Two studies highlighted HIV-associated impairments in nonverbal abilities and in planning. Regarding methodological quality, shortcomings included reporting and selection biases.
**Conclusions:** This systematic review provides evidence for the cross-cultural utility of the KABC/KABC-II (particularly the simultaneous processing subtests) in detecting HANI in HIV-infected children, even those who are clinically stable. Although the current results suggest there is justification for using the KABC/KABC-II in Africa, further investigation is required to explore the instrument's utility in other regions where HIV is also prevalent.

## TUPEB121

### SUCCESS RATE WITH MRI NEUROIMAGING RESEARCH IN UN-SEDATED YOUNG HIV-INFECTED CHILDREN USING SIMULATION SCAN PREPARATION

T. van de Water[1,2], T. Hamana[1], I. Op't Hof[3], M.J. Holmes[4], M. Zunza[1,5], M.F. Cotton[1], A.J.W. van der Kouwe[6,7], E.M. Meintjies[3,4], B. Laughton[1]
*[1]Stellenbosch University, Family Clinical Research Unit, Department of Pediatrics, Cape Town, South Africa, [2]Stellenbosch University, South African Research Chair Initiative - PTSD, Department of Psychiatry, Cape Town, South Africa, [3]University of Cape Town, Cape Universities Body Imaging Centre, Department of Human Biology, Cape Town, South Africa, [4]University of Cape Town, MRC/UCT Medical Imaging Research Unit, Department of Human Biology, Cape Town, South Africa, [5]Stellenbosch University, Biostatistics Unit, Centre for Evidence Based Health Care, Department of Interdisciplinary Health Sciences, Cape Town, South Africa, [6]Massachusetts General Hospital, A. A. Martinos Centre for Biomedical Imaging, Department of Radiology, Charlestown, United States, [7]Harvard Medical School, Radiology, Boston, United States*
*Presenting author email: hamana@sun.ac.za*

**Background:** Magnetic resonance neuroimaging (MRI) studies involving children are difficult because participants must remain motionless for extended periods without sedation. We describe the success rate for un-sedated 5- and 7-year-old children on a 3T Allegra MRI (Siemens, Erlangen).
**Methods:** Children from a neuroimaging sub-study of the Children with HIV Early Antiretroviral Therapy (CHER) trial were scanned at 5 and 7 years. The sample comprised HIV infected (HIV+) and HIV negative (HIV-) including exposed- and unexposed uninfected participants. Children who tolerated a simulation scanner re-

turned for neuroimaging during which the child watched a movie of his/her choice. The hour-long protocol included structural, diffusion tensor, and spectroscopic imaging, with the addition of resting state functional MRI at 7 years. We collected information on image acquisition (those who arrived and provided at least one scan sequence), scanner tolerance (arrived and calm in scanner the entire session), and neuroimaging data usability assessed using Freesurfer, LCModel, FSL and AFNI software. The effect of HIV exposure and gender on success rates was explored.
**Results:** At 5 years, 115 (male 57, HIV+ 73) participated with 139 (male 71, HIV+ 80) at 7 years. The mean±SD usable images was 5±1.3 and 6±1.2 at 5 and 7 years respectively. Image usability was influenced by HIV status at 5 years (HIV+ 5±1.3; HIV- 3±1, p=0.0067), and gender at 7 years (girls 6±1; boys 5±1.2, p=0.004). Success rates improved significantly in the 102 participants (79%) already participating at 5 years (male 50, HIV+ 73): image acquisition (75% to 94%; p< 0.001), scanner tolerance (20% to 60%; p< 0.001), and full scan data perfectly usable if appointment kept (7% to 21%; p=0.0015).
**Conclusions:** Success rates of neuroimaging in un-sedated young children improved with age. Image usability was higher in HIV+ children, who are potentially more comfortable with medical procedures and thus more tolerant. Although completely successful image acquisition and usability as per protocol is unlikely, a similar average number of useable images are collected at both time points when using the simulation scan preparation. Sample size calculations should consider the challenges of patient withdrawal and distress in young children.

## TUPEB122

### HIV-INFECTED CHILDREN WHO INITIATED ART DURING INFANCY (EARLY ART) HAVE IMPROVED NEUROCOGNITIVE OUTCOMES COMPARED WITH LATE-TREATED CHILDREN

S. Benki-Nugent[1], D. Wamalwa[2], T. Laboso[3], N. Tamasha[3], M. Otieno[3], P. Bangirana[4], K. Tapia[1], B. Richardson[5,6], E. Obimbo[7], M.J. Boivin[8], M. Semrud-Clikeman[9], G. John-Stewart[1]
*[1]University of Washington, Global Health, Seattle, United States, [2]University of Nairobi, Department of Paediatrics and Child Health, Nairobi, Kenya, [3]University of Nairobi, Nairobi, Kenya, [4]Makerere University, Psychiatry, Kampala, Uganda, [5]University of Washington, Biostatistics, Seattle, United States, [6]Fred Hutchinson Cancer Research Center, Seattle, United States, [7]University of Nairobi, Paediatrics and Child Health, Nairobi, Kenya, [8]Michigan State University, East Lansing, United States, [9]University of Minnesota, Pediatrics, Minneapolis, United States*
*Presenting author email: benki@u.washington.edu*

**Background:** HIV-infected children have high risk of learning and behavior difficulties at school-age. The long-term benefit of early antiretroviral treatment (infancy) for reducing these risks is unknown.
**Methods:** Antiretroviral treatment (ART) was initiated with Kenyan HIV-infected infants at age < 12 months (early-treated; 2007-2009) or at age 18-60 months (late-treated; (2004-2008). Neurocognitive assessments were completed at school-age and adolescence. Assessments included the Kaufman Assessment Battery for Children 2nd edition (cognitive ability, short-term memory, visual-spatial processing, planning, learning, and non-verbal), Test of Variables of Attention (attention), and Bruininck's-Oseretsky Test of Motor Proficiency-2 (motor). Age-matched (to the early-treated group) HIV-exposed-uninfected (HEU) and HIV-unexposed-uninfected (HUU) children were also assessed. Scores were standardized using US norm data to allow cohort comparisons. Standardized scores were compared using multivariable linear regression analyses adjusted for caregiver years of education, to account for socioeconomic differences.
**Results:** At neurocognitive assessment, median ages were 6.7 years (HUU; N=63), 7.4 years (HEU; N=34), 6.9 years (HIV+ early-treated; N=54) and 13.4 years (HIV+ late-treated; N=25). Early and late-treated children initiated ART at a median 0.4 and 3.3 years of age, respectively. Mean scores in HUU children were 75.0 (cognitive), 83.3 (short-term memory), 73.4 (visual-spatial processing), 86.2 (learning), 71.3 (planning), 72.8 (non-verbal), 83.1 (attention), and 44.6 (motor). In multivariable analyses, compared with HUU children, HIV+ early-treated children had lower scores for short-term memory (adjusted mean difference, -5.15; P=0.015). Compared with HUU children, HIV+ late-treated children had significantly lower scores (adjusted mean differences, cognitive ability, -8.80; P=0.002; short-term memory -11.77; P< 0.001; visual-spatial processing, -7.97; P=0.02; non-verbal, -9.36; P=0.004; motor, -9.48; P< 0.0001). Compared with early-treated children, late-treated children also had significantly lower scores (adjusted mean differences, short-term memory, -6.38; P=0.03; learning, -7.14; P=0.04, non-verbal, -6.76, P=0.02, and motor -7.13, P=0.001).
**Conclusions:** Children who had received ART by age one year had subtle short-term memory deficits compared with HUU. Children who initiated ART later had deficits in multiple domains including cognition, short-term memory, visual-spatial processing, learning and motor skills, compared with HUU or HIV+ early-treated children or both. Earlier ART appears to prevent broader neurodevelopmental compromise due to pediatric HIV infection.

## TUPEB123

### MENTAL HEALTH AND ASSOCIATED VIROLOGIC OUTCOMES AMONG HIV-INFECTED ADOLESCENTS IN TANZANIA

D. Dow[1,2,3], A. Shayo[3], E. Turner[4], B. Mmbaga[3], C. Cunningham[1,2], K. O'Donnell[5,6]
*[1]Duke University Medical Center, Pediatrics, Infectious Diseases, Durham, United States, [2]Duke Global Health Institute, Durham, United States, [3]Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of, [4]Duke University, Department of Biostatistics and Bioinformatics, Durham, United States, [5]Duke University, Center for Health Policy and Inequalities Research, Durham, United States, [6]Duke University, Center for Child and Family Health, Durham, United States*
*Presenting author email: dorothy.dow@duke.edu*

**Background:** Sub-Saharan Africa is home to more than 80% of the estimated 2.1 million HIV-infected adolescents. Despite this HIV burden, few studies have evaluated mental health difficulties (MHD) and associated HIV outcomes. This study aimed to describe MHD and associated HIV outcomes in HIV-positive adolescents in Tanzania.
**Methods:** This prospective, cross-sectional study enrolled HIV-infected adolescents between 11 to 24 years of age who attend adolescent clinic at KCMC (referral center) or Mawenzi (government hospital) in Moshi, Tanzania. Assessments included: Patient Health Questionnaire (PHQ-9)—depression (cut off ≥10; range (0-27); Strengths and Difficulties Questionnaire (SDQ)—behavioral and emotional symptoms (cut off ≥17; range 0-40); modified UCLA PTSD Reaction Index (PTSD-RI)—post traumatic stress symptoms (cut off ≥18; range (0-51). MHD were defined as meeting the threshold criteria on any one of the three mental health measures. Self-reported adherence and a modified Berger Stigma Scale—(10 questions, cutoff ≥24; range (10-40) were also assessed. HIV-RNA was obtained after questionnaire was completed.
**Results:** Adolescents from KCMC (n=182) or Mawenzi (n=98) were enrolled. Comparative data of key variables are reported (Table I). Youth at Mawenzi had significantly more MHD, stigma, and incomplete adherence as compared to KCMC. Univariable regression analysis of the combined cohorts demonstrated a 13% increased odds of MHD per one unit increase in stigma (CI 1.07 - 1.19) and 86% increased odds of MHD for adolescents who self-reported incomplete adherence (CI 1.09 - 3.17). MHD were not statistically associated with virologic failure (≥ 400 copies/mL) for adolescents receiving ART.

| Demographic - n (%) unless otherwise specified | KCMC (n=182) | Mawenzi (n=98) | p value |
|---|---|---|---|
| Age (years)- mean (SD) | 17.2 (2.9) | 15.9 (2.3) | 0.45 |
| Female | 99 (54.4%) | 56 (57.1%) | 0.67 |
| Mental Health Difficulties | 46 (25.3%) | 44 (44.9%) | <0.01 |
| Depressive symptoms (PHQ > 10) | 22 (12.1%) | 35 (35.7%) | 0.01 |
| Emotional/behavioral symptoms (SDQ > 17) | 25 (13.7%) | 23 (23.5%) | 0.04 |
| Post-traumatic symptoms (PTSD-RI > 18) | 19 (10.4%) | 19 (19.4%) | 0.03 |
| Significant Stigma > 24 | 42 (23.1%) | 35 (35.7%) | 0.02 |
| Self-Reported Incomplete Adherence | 43 (23.6%) | 45 (45.9%) | <0.01 |
| HIV-1 RNA >400 copies/mL and receiving ART | 71 (45.8%) *n=155 | 35 (38.5%) *n=91 | 0.46 |

*[Comparison of HIV-Infected Adolescent Cohorts from Two Adolescent Clinics in Tanzania]*

**Conclusions:** Self-reported MHD were considerable among HIV-infected adolescents and were significantly associated with stigma and incomplete adherence. Virologic failure was also prevalent, though did not meet statistical significance. MHD were more prevalent among youth attending the lower income clinic, Mawenzi. Research on innovative mental health interventions to address the needs of this growing HIV-infected adolescent population is urgently needed.

# RETENTION IN CARE OF ADOLESCENTS

## TUPEB124

### HIGH RETENTION AND VIRAL SUPPRESSION RATES IN A DEDICATED ADOLESCENT-FRIENDLY HIV CLINIC IN SOUTH AFRICA

B. Zanoni[1], C. Cairns[2], J. Haberer[3]
*[1]Massachusetts General Hospital, Infectious Disease, Boston, United States, [2]Don McKenzie Hospital, Botha's Hill, South Africa, [3]Massachusetts General Hospital, Boston, United States*
*Presenting author email: bzanoni@mgh.harvard.edu*

**Background:** South Africa has the highest burden of HIV-infected youth globally. Adolescents with chronic illness commonly struggle with poor adherence. Studies from resource-rich countries have documented high rates of mortality, loss to follow-up, and virologic failure among HIV-infected adolescents. To overcome these challenges, many HIV clinics have initiated adolescent-friendly services; however, outcomes in these clinics have not been described.

**Methods:** We performed a retrospective cohort analysis using medical records from 254 perinatally HIV-infected adolescents receiving antiretroviral therapy (ART) at a single clinic in KwaZulu-Natal, South Africa from April 2007 to November 2015. Adolescents could attend either: 1) Saturday teen clinic with dedicated peer support and structured social activities after six months on ART pending availability or remain in 2) standard weekday pediatric clinic. We analyzed records from all perinatally HIV-infected adolescents/young adults aged 13 - 24 attending teen clinic or standard pediatric clinic. We performed a cross-sectional analysis comparing retention in care and viral suppression among adolescents attending each clinic. We calculated descriptive statistics and conducted univariable and multivariable logistic regression models.

**Results:** Overall, viral suppression among adolescents was 85% (196/231) and retention was 89% (226/254) with retention outcomes in 97%. We found significantly higher retention among adolescents attending teen clinic (97%) versus standard clinic (85%; p=0.005). Multivariable logistic regression adjusting for age at ART initiation, gender, pre-ART CD4, months on ART and tuberculosis history indicated higher retention in adolescents attending teen clinic compared to standard clinic (OR =10.1; p=0.003). We also found higher viral suppression among adolescents attending teen clinic (91%) versus standard clinic
(81%; p=0.048). A similar multivariable logistic regression model indicated higher viral suppression in adolescents attending teen clinic compared to standard clinic (OR = 4.13; p=0.004).

| | Prevalence | | | Multivariable Analysis | |
|---|---|---|---|---|---|
| | Teen Clinic (n=88) | Standard Clinic (n=166) | P-value | Retention OR (P-value) | Viral Suppression OR (P-value) |
| **Median age at ART initiation (IQR)** | 11.0 (9.4 - 12.7) | 9.6 (7.6 - 12.2) | **0.014** | **0.90 (0.044)** | 0.91 (0.081) |
| **Female (%)** | 50 (57%) | 82 (49%) | 0.260 | **0.27 (0.021)** | 0.98 (0.967) |
| **Median pre-ART CD4 (IQR)** | 94 (35 - 220) | 205 (98 - 345) | **<0.001** | 1.00 (0.394) | 1.00 (0.161) |
| **Median Months on ART (IQR)** | 72 (52 - 92) | 58 (27 - 83) | **<0.001** | 1.00 (0.469) | 0.99 (0.223) |
| **Tuberculosis History** | 42 (49%) | 92 (55%) | 0.243 | 0.91 (0.849) | 1.66 (0.453) |
| **Teen Clinic Attendance** | ___ | ___ | ___ | **10.12 (0.003)** | **4.13 (0.004)** |

*[Table 1: Outcomes of Adolescents Attending Teen Clinic and Standard Clinic]*

**Conclusions:** Despite lower pre-ART CD4 and older age at initiation, adolescents attending a teen clinic had higher retention in care and viral suppression compared to adolescents attending standard pediatric clinic.

## TUPEB125

### IMPACT OF A YOUTH-TARGETED HIV CLINIC INTEGRATED WITHIN A LARGE URBAN ADULT CLINIC

D. Griffith, J. Keruly, L. Lee, K. Nolan, A. Agwu
*Johns Hopkins University, Baltimore, United States*
*Presenting author email: dgriff50@jhmi.edu*

**Background:** In the US, adolescents/young adults make up the largest proportion of new HIV infections and the majority who engage in care do so at adult clinical sites. Youth Living with HIV (YLHIV) have worse retention and suppression outcomes than adults. Given these challenges, new models are needed to improve outcomes for YLHIV. We evaluated the impact on retention in care of comprehensive youth-targeted care within an adult clinic.

**Methods:** The Access Care Early (ACE) program for YLHIV is integrated within a large adult HIV clinic. Patients 18-30 years qualify for ACE for the following: transfer from pediatric care; newly diagnosed high risk (e.g. mental illness, substance abuse); lack of success in standard adult care. ACE providers have combined internal medicine-pediatrics training and comprehensive care is provided through ACE's team of social work, nursing, mental health, and youth outreach worker. We performed a retrospective analysis of patients 18-30 years who newly presented to care after June 2012 and compared 1-year retention of those cared for in ACE versus those receiving standard care in the adult clinic. Measures of engagement were ≥6 month gap in care and minimum of 2 visits ≥ 90 days apart.

**Results:** Of the 132 YLHIV meeting inclusion criteria, 54 (41%) received care in ACE (24/54 transitioned from pediatric HIV care; 16/24 were perinatally acquired) and 78 (59%) received standard adult care. Demographics were similar, except ACE patients were younger. YLHIV in ACE were less likely to have a 6 month gap in care (44% vs. 59%, p 0.10) and more likely to have two appointments ≥ 90 days apart compared to those receiving standard adult care (83% vs. 69%, p 0.066).

| Variable | Youth Targeted Care N= 54 (41%) | Standard Adult Care N=78 (59%) | Total N=132 (100%) | p-value ($\chi^2$) |
|---|---|---|---|---|
| Age, median (range) | 24 (18-29) | 26 (20-30) | 25 (18-30) | 0.001 (t-test) |
| Male | 37 (69%) | 63 (81%) | 100 (76%) | 0.106 |
| Race:Black/White/ Hispanic | 46(85%)/ 5(9%)/1(2%) | 55(71%)/ 13(17%)/5(6%) | 101(77%)/ 18(14%)/6(5%) | 0.28 |
| 6 month gap | 24 (44%) | 46 (59%) | 70 (53%) | 0.100 |
| 2 visits >90 days apart | 45 (83%) | 54 (69%) | 99 (75%) | 0.066 |

*[Characteristics and retention for YLHIV followed in Youth Targeted (ACE) vs. Standard Adult Care]*

**Conclusions:** Despite targeting YLHIV with significant challenges to retention, YLHIV enrolled in the ACE program had a trend toward better retention in care. Further studies of ACE and similar programs may inform development of future interventions to improve the continuum of care in this high-risk population within adult clinics.

## TUPEB126

### PROJECT REACH: A FACILITY-BASED PEER SUPPORT MODEL ACROSS 20 FACILITIES IN FIVE SUB-SAHARAN AFRICAN COUNTRIES

D. Mark[1,2], A. Ngombe[1], G. Burford[3], N. Renaud[3], V. Djoumessi[1], E. Tunnacliffe[3], L. Hatane[1], L. Montewa[4]
*[1]PATA, Cape Town, South Africa, [2]University of Cape Town, Psychology, Cape Town, South Africa, [3]One to One Children's Fund, London, United Kingdom, [4]Paediatric Aids Treatment for Africa, Cape Town, South Africa*
*Presenting author email: lebogang@teampata.org*

**Background:** AIDS is now the leading cause of death among adolescents (age 10-19 years) in Africa. Emerging evidence suggests that peer-led service delivery models may improve outcomes and health service engagement for adolescents and young people living with HIV (AYPLHIV). However, greater evidence is needed for these models to emerge as policy and be implemented at scale with established standards and principles.

**Description:** Project Re-Engage Adolescents and Children with HIV (REACH) aims to investigate a health facility-based peer support model to improve HIV treatment and care services for and treatment outcomes in children and AYPLHIV. The program engages 59 AYPLHIV age 18-24 years as peer supporters in 20 health facilities across five sub-Saharan African countries (Ethiopia, Uganda, Malawi, DRC and Cameroon). Peer supporters receive monthly stipends, relevant nationally-accredited training and a practical toolkit to prepare them to deliver peer-led psychosocial services, educate and engage communities and provide operational support.

**Lessons learned:** Project REACH facilities span urban, peri-urban and rural (59%; 24%; 17%) and primary, secondary and tertiary level (35%; 24%; 41%) settings, providing evidence and examples across contexts. Together, these facilities provide HIV treatment and care for 21,523 children and AYPLHIV. Since the program's launch in April 2015, the adolescent patient base at participating facilities has increased by 10%. Facilities have initiated new AYPLHIV-supportive services and activities, including home visits (82%); outcomes monitoring (88%); standardised disclosure (71%) and dedicated AYPLHIV-friendly visit times (71%). Peer supporters primarily deliver psychosocial support, such as support groups and counseling (80%); conduct home visits and treatment literacy sessions (90%); and perform facility-based task-sharing like basic patient monitoring (50%). 83% of facilities provide peer supporters with employment contracts, 90% conduct performance appraisals and 90% include them in case meetings.

**Conclusions/Next steps:** Health facilities have a central responsibility to provide sustainable services that are responsive to the needs of AYPLHIV within an enabling environment. Project REACH demonstrates the critical role that facility-based peer supporters may play in expanding adolescent treatment access and addressing gaps in AYPLHIV-friendly services. Results show that peer supporters can be assimilated into health facility teams, but true integration will require policy shifts and health systems strengthening.

## TRANSITION INTO ADULT CARE

### TUPEB127

### TRANSITIONING HIV-INFECTED CHILDREN INTO ADULT CARE: VOICES OF JAMAICAN ADOLESCENTS AND THEIR HEALTHCARE PROVIDERS

F. De Souza[1], E. Paintsil[2], T. Brown[3,4], R. Pierre[5], D. Keene[6], N. Kim[1], C. Christie[7]
*[1]Yale School of Medicine, New Haven, United States, [2]Yale School of Medicine, Department of Pediatrics, New Haven, United States, [3]Ministry of Health, South East Regional Health Authority, Kingston, Jamaica, [4]University of the West Indies, Kingston, Jamaica, [5]University of the West Indies, Child and Adolescent Health, Kingston, Jamaica, [6]Yale School of Public Health, Chronic Disease Epidemiology: Social and Behavioral Sciences, New Haven, United States, [7]University of the West Indies, Department of Child and Adolescent Health, Kingston, Jamaica*
*Presenting author email: flavia.desouza@yale.edu*

**Background:** Successful public access to antiretroviral therapy in resource-limited settings (RLS) has resulted in survival of HIV perinatally-infected children into adulthood. However, there are few studies or guidelines on transition of care in RLS, where 90% of HIV-infected children reside. We aimed to characterize the current landscape of the transfer process of HIV-infected adolescents from the perspectives of both the adolescents and providers in one such RLS, Jamaica.
**Methods:** We conducted in-depth semi-structured interviews of 18 HIV-infected adolescents in paediatric care at the University Hospital of the West Indies and 21 health care providers from various clinics across Jamaica. We audiotaped, transcribed verbatim, then organized and coded transcripts using the software ATLASti. We analysed the data using the grounded theory approach.
**Results:** Five themes emerged:
1. Adolescent patients articulated psychosocial benefits associated with pediatric care. Pediatric clinics were like families who provided care-taking and developmental support in addition to HIV care.
2. Both adolescent patients and pediatric providers felt the quality of care adolescents received in the pediatric clinic was better than it would be in the adult setting.
3. Given the social significance of pediatrics clinics in participants' lives, alongside the concerns regarding adult care, there was rootedness in the pediatric clinic and apprehension about transfer to the adult clinic.
4. In the face of the national policy of transfer to adult care at 13, no formalized national structures or services for adolescents, and the challenges HIV-infected adolescents experience, some physicians sought to bridge the gap between childhood and adulthood by providing adolescent-centered services for their HIV-infected clients.
5. Narratives speak to the transfer as a critical juncture in adolescents' care and a transition as a holistic and gradual process, an element of which is the transfer.
**Conclusions:** A formal, culturally, and developmentally appropriate process of transition is necessary to manage the fear and apprehension both providers and adolescent patients experience when confronted with the transfer from pediatric to adult care.

## TRENDS IN MORBIDITY AND MORTALITY

### TUPEC128

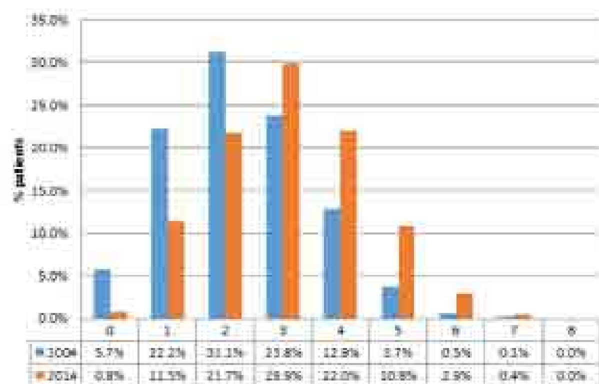
### EVOLUTION OF RISK FACTORS FOR CHRONIC KIDNEY DISEASE IN THE FRENCH ANRS CO3 AQUITAINE COHORT, 2004-2014

F. Bonnet[1], F. Le Marec[2], O. Leleux[2], C. Cazanave[3], E. Lazaro[1], P. Duffau[1], M.-A. Vandenhende[1], P. Mercie[1], D. Neau[3], F. Dabis[4]
*[1]Service de Médecine Interne et Maladies Infectieuses, CHU Bordeaux, Bordeaux, France, [2]INSERM U 893, ISPED, Université de Bordeaux, Bordeaux, France, [3]Service de Maladies Infectieuses et Tropicales, CHU de Bordeaux, Bordeaux, France, [4]ISPED, INSERM, Bordeaux University, Bordeaux, France*
*Presenting author email: francois.dabis@isped.u-bordeaux2.fr*

**Background:** Long-term management of an aging HIV positive population could be impacted by comorbidities as chronic kidney disease (CKD). Thus, monitoring their risk factors are important to target prevention. The objectives were to compare patients' profile of ANRS CO3 Aquitaine cohort between 2004 and 2014 regarding epidemiological characteristics and comorbidities, including CKD risk factors as proposed in the 2013 French guidelines and literature (Mocroft PLoS Med. 2015; 12(3):e1001809).
**Methods:** Two repeated cross-sectional analyses were performed using Aquitaine Cohort data. In this prospective open cohort, epidemiological, clinical, therapeutic and biological, data are systematically collected in a standardized way on all patients in care, with informed consent, in public hospitals in south Western, France. Eligible patients had ≥1 clinic visit in 2004 and 2014.
**Results:** The patients' CKD risk factors in 2004 and 2014 are displayed in table. In ten years, the age category ≥50 years was multiplied by 2.5 and the African origin increased by 60%; all biological risk factors (except hepatitis co-infection) increased over time. In 2004, 41% of patients had ≥3 CKD risk factors which increased to 66% in 2014 (figure). In 2004, 33.4% of the cohort had low (< 0) risk score for CKD, 35% medium (0-4) score and 31.6% high-risk score (≥5) vs 21.8%, 32.7% and 45.5% of patients in 2014, respectively.

| CKD risk factors (2013 French Guidelines) | 2004 (n=3,290) | 2014 (n=3,880) |
|---|---|---|
| Age ≥ 50 years (%) | 20.9 | 52.3 |
| Female (%) | 27.5 | 28.2 |
| African origin (%) | 7.1 | 11.4 |
| HBV/HCV co-infection (%) | 38.1 | 28.5 |
| Prevalence of hypertension (%) | 4.3 | 17.8 |
| Prevalence of diabetes (%) | 9.4 | 14.2 |
| Prevalence of dyslipidaemia (%) | 14.3 | 46.1 |
| CD4 count <200/mm3 mid-year (%) | 12.4 | 4.1 |
| Exposure to indinavir, atazanavir and TDF (%) | 29.5 | 72.9 |

*[Table]*



*[Figure. Proportion of patients by number of renal risk factors in 2004/2014 (Morlat 2013 Criteria)]*

**Conclusions:** Over time, with ageing, the prevalence of CKD risk factors has increased and infectious comorbidities decreased. Follow-up procedures should emphasize the prevention / correction of risk factors amenable to prevention.

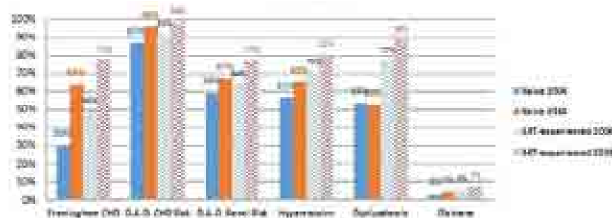
### EVOLUTION OF COMORBIDITIES IN HIV PATIENTS IN ITALIAN ICONA COHORT: CROSS-SECTIONAL ANALYSIS IN 2004 AND 2014

A. d'Arminio Monforte[1], F. Aragão[2], A. De Luca[3], F. Maggiolo[4], A. Cingolani[5], F. Mazzotta[6], S. Bonora[7], A. Castagna[8], E. Girardi[9], A. Antinori[9], A. Cozzi-Lepri[10]
*[1]Inst Infectious Diseases University of Milan, Milan, Italy, [2]Gilead Sciences, EAME Medical Affairs Department, London, United Kingdom, [3]Div Infectious Diseases, DPT of Medical Biotechnologies, University of Siena, Siena, Italy, [4]Giovanni XXIII Hospital, Dept Infectious Diseases, Bergamo, Italy, [5]Inst Infectious Diseases Cattolica University, Rome, Italy, [6]Bagno A Ripoli Hospital, Dept Infectious Diseases, Firenze, Italy, [7]Inst Infectious Diseases University of Torino, Torino, Italy, [8]Inst Infectious Diseases Universityvita E Salute, Milano, Italy, [9]INMI L Spallanzani, Rome, Italy, [10]UCL, London, United Kingdom*
*Presenting author email: antonella.darminio@unimi.it*

**Background:** Because life expectancy of people with HIV, although extended by cART, largely depends on their stage of HIV disease progression and co-morbidities when first seen for care, estimates of the prevalence of AIDS and non-AIDS morbidity are crucial to plan their long-term management.
**Objectives:** Describe demographics, HIV markers and comorbidities in ART-naïve patients in ICONA cohort and compare their characteristics with ART-experienced population according to current calendar year (2004 and 2014).
**Methods:** A cross-sectional analysis was performed after population stratification in 4 mutually exclusive groups who were under active follow-up in 2004 or 2014 according to previous treatment history (ART-naïve vs. -experienced). People were included if they were seen for care at least once in the year. ART-naïve patients were defined as those who, by December 31st of the year, had not started ART.
**Results:** Table summarises patients' demographics and HIV disease characteristics. Figure shows the prevalence of non-AIDS comorbidities. In 2014, ART-naïve people were older, showed higher CD4 count and less frequently AIDS. ART-naïve patients in 2014 presented increased risk for renal, CHD and hypertension and similar prevalence of diabetes and dyslipidaemia. Overall>50% showed moderate or high risk of comorbidities. These were, on average, higher in ART-experienced, regardless of calendar year.

| | ART-naive | | | ART-experienced | | | |
|---|---|---|---|---|---|---|---|
| Characteristics | 2004 (N= 471) | 2014 (N= 95) | p-value | 2004 (N= 1680) | 2014 (N= 1826) | p-value | Global p-value |
| **Age, Median (IQR)** | 40 (34, 44) | 50 (45, 53) | 0.206 | 41 (37, 46) | 50 (46, 55) | 0.381 | 0.044 |
| **Gender, Female n(%)** | 149 (31.6%) | 26 (27.4%) | 0.835 | 523 (31.1%) | 584 (32.0%) | 0.346 | 0.537 |
| **CD4 count >500 cells/mm3 n(%)** | 236 (52.7%) | 60 (69.0%) | 0.015 | 763 (46.2%) | 1366 (75.1%) | 0.198 | 0.013 |
| **HIV RNA, copies/mL n(%)** | | | <.001 | | | <.001 | <.001 |
| **0-80** | 8 (2.0%) | 3 (4.5%) | | 847 (51.3%) | 1651 (90.8%) | | |
| **81-100,000** | 366 (90.1%) | 58 (87.9%) | | 709 (42.9%) | 157 (8.6%) | | |
| **>100,000** | 32 (7.9%) | 5 (7.6%) | | 95 (5.8%) | 10 (0.6%) | | |
| **AIDS diagnosis, n(%)** | 17 (3.6%) | 0 (0.0%) | <.001 | 346 (20.6%) | 294 (16.1%) | <.001 | <.001 |

*[Table 1]*



*[Figure 1. Proportion of patients with moderate/high risk of coronary heart disease and chronic kidney disease, and prevalence of hypertension, dyslipedemia and diabetes]*

**Conclusions:** The prevalence of comorbidities and risk factors in ART-naïve patients is lower than that in the experienced population. However, because it is considerably high and higher than that of ART-naïve patients a decade ago it is likely to influence the type of care of these patients.

## TUPEC130

### PRE-ART MORTALITY FOR ADULTS HIV PATIENTS ENROLLED INTO PUBLIC-DRIVEN HIV CARE PROGRAM IN MWANZA REGION TANZANIA (2011-2014), A COMPETING RISK ANALYSIS

J. Nondi[1], J. Todd[2], J. Renju[3], G. Somi[1], D.A. Ramadhani[4]
*[1]National AIDS Control Program Tanzania, Dar es Salaam, Tanzania, United Republic of, [2]London School of Hygiene and Tropical Medicine/TAZAMA Project/SEARCH Project, Mwanza, Tanzania, United Republic of, [3]Kilimanjaro Christian Medical College/ SEARCH Project, Kilimanjaro, Tanzania, United Republic of, [4]National AIDS Control Programme, Ministry of Health, Community Development, Gender, Elderly and Children, Dar Es Salaam, Tanzania, United Republic of*
*Presenting author email: josenondi@yahoo.co.uk*

**Background:** In many African HIV programmes, patients initiate antiretroviral therapy (ART) based on clinical or immunological criteria. Mortality rates following ART initiation are high because patients present with advanced stage of the disease. However, prior to ART initiation, high mortality rates are also seen among HIV infected patients in resource limited settings, although little has been done to understand the pre-ART mortality rates. We analysed routinely collected patient-level data from the government driven HIV programme to determine these rates.
**Methods:** Survival analysis was used to estimate mortality rates before ART initiation. Follow-up time was from date of clinic enrolment to death - defined if patient records had a date of death and no ART start date. Censoring was defined as the date for Lost-to-follow-up (LTFU), ART start date, or at last clinic visit, global censoring at 31st December 2014. In the analysis, LTFU was considered a competing event, as this can be due to death (ie non-independence from the outcome). Age specific mortality rates per 100 follow-up years were calculated. Competing-risk regression models were used to compare the hazards experienced by sub-groups when enrolling into clinics and before ART start.
**Results:** Of 32,205 HIV positive adults who enrolled in clinics between 2011 and 2014, there were 21,501 (64.8%) females. During follow up, 752 adults died prior to ART initiation with overall pre-ART mortality of 2.64 (2.45-2.83) per 100 person years and 5,942 were lost to follow-up. Mortality rates increased with age at enrolment (from 1.48 in 15-19 age-group to 4.50 in those 60+ age-group). Mortality rates decreased with increasing CD4 counts at enrolment (from 2.72 at <200 cells/ml to 1.03 at 500+ cells/ml) but increased with higher WHO stage at enrolment (1.38 at Stage 1 to 7.94 at Stage 4). Competing risk analysis showed increasing hazard ratios with older age.
**Conclusions:** The crude per-ART mortality rate of 2.64 per 100 person-years is about eight times higher than the background adult mortality rate in most African countries. The competing risk analysis highlighted the underreporting of deaths among older age groups who were LTFU.

## TUPEC131

### REGIONAL DIFFERENCES IN AIDS MORTALITY IN MEXICO: A CHALLENGE TO SOLVE

E. Bravo-García[1], C. Magis-Rodríguez[2], H. Ortiz-Pérez[3], J.S. Bravo-García[4]
*[1]Spectrum, Educación, Salud y Sociedad, A.C, México, Mexico, [2]National Center for the Prevention and Control of HIV/AIDS and STIs, Mexico, Mexico, [3]Universidad Autónoma Metropolitana - Xochimilco, Departamento de Atención a la Salud, México, Mexico, [4]Independent Database Advisor, México, Mexico*
*Presenting author email: carlos.magis@gmail.com*

**Background:** Mexico has provided free access to HAART since 2003. However, AIDS mortality rates have not decreased as expected, reducing only from 4.4 deaths per 100,000 inhabitants in 2003 to 4.2 in 2013. Regional differences are huge and the early diagnosis of HIV, quality of care, and socioeconomic status have been reported as determinants of health of people living with AIDS.
**Methods:** We estimate AIDS mortality rates from data for State level (2003-2013), and the average annual mortality rate in the 2437 Municipalities in Mexico (2009-2013). We identified the States and 25 Municipalities (20,000+ inhabitants) with the highest mortality rates. Data were correlated with the early diagnosis of HIV, quality of care and poverty.
**Results:** Tabasco (10.58 per 100 000 inhabitants), Quintana Roo (9.02), and Veracruz (8.65) were the Mexican states with the highest AIDS mortality rates; Zacatecas (1.03), Guanajuato (1.43) and Hidalgo (1.92) recorded the lowest rates. From 2003 to 2013, in 50% of Mexican states (16/32), the AIDS rates increased, rather than decreased. The difference between the states with the highest and lowest rate (Tabasco and Zacatecas) was more than seven times.
The 25 Municipios with the highest mortality rates are located only in five states, all of them in the Southeast and among the poorest in the country: Veracruz, Chiapas, Tabasco, Campeche and Oaxaca. The Municipio of Carlos A. Carrillo, Veracruz, ranked number one with a rate of 39.6 deaths per 100,000 inhabitants (nine times higher than the national rate), and Poza Rica, Veracruz, being number 25 with a rate of 13.4.

[25 municipios with highest AIDS mortality rates in Mexico (2009-2013)]

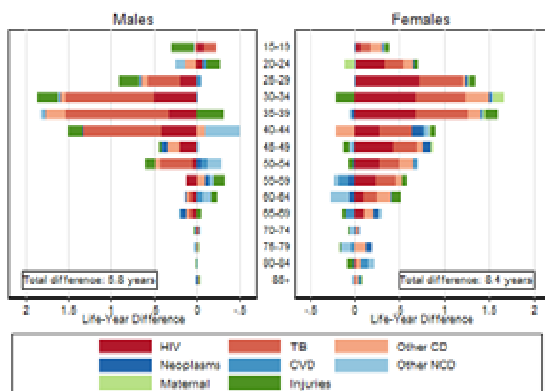
**Conclusions:** The data highlight the need for enhanced HIV detection and treatment for 25 Municipios with the highest AIDS mortality rates, as well as the States most affected. Findings can help to identify the sites where resources should be targeted to reduce AIDS mortality in Mexico.

## TUPEC132

### THE RAPIDLY SHRINKING BURDEN OF HIV ON ADULT MORTALITY IN KWAZULU-NATAL, SOUTH AFRICA

G. Reniers[1,2], S. Blom[1], A. Martin-Onraet[1], K. Herbst[3], C. Calvert[1], J.W. Eaton[4], J. Bor[5], E. Slaymaker[1], Z.R. Li[6], T. Bärnighausen[3,7], B. Zaba[1], V. Hosegood[3,8]
*[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Africa Centre for Health and Population Studies, Mtubatuba, South Africa, [4]Imperial College, London, United Kingdom, [5]Boston University, Boston, United States, [6]University of Washington, Seattle, United States, [7]Harvard University, Boston, United States, [8]University of Southampton, Southampton, United Kingdom*
*Presenting author email: georges.reniers@lshtm.ac.uk*

**Background:** Adult mortality declined considerably since the expansion of antiretroviral therapy (ART) programs, but the residual burden of HIV on adult mortality in generalized epidemics remains poorly understood.
**Methods:** We use demographic and HIV surveillance data from 2001 to 2014 covering a rural South African population of around 45,000 individuals aged 15 to 100. We use non-parametric survival analysis for estimating (i) population-wide adult LE gains since the introduction of ART in 2004, and (ii) the shortfall of the adult LE compared to that of the HIV negative population (i.e., the LE deficit). LE gains and deficits for groups of calendar years are decomposed by age and cause of death with data generated by a new verbal autopsy interpretation tool (InSilicoVA). All estimates are disaggregated by sex.
**Results:** Since the roll-out of ART, population-level adult LE has increased by 15.2 years for men (95%-CI: 12.4-17.8), and 17.2 years for women (95%-CI: 14.5-20.2). Reductions in TB and HIV related mortality account for 80% of the LE gains among men, and over 90% among women. For men, 10% is the result of a decline in external injuries. As a result of the mortality reductions, the LE deficit in 2014 had contracted to 1.2 years for men (95%-CI: -2.0-5.0) and to 5.3 years for women (95%-CI: 2.8-7.8). TB and HIV are responsible for over 90% of the LE deficit among men in 2011-'14, and for over 84% among women. The remainder is largely attributed to other communicable diseases (Figure 1).
**Conclusions:** The burden of HIV on adult mortality in this population is rapidly shrinking, but remains sizable for women, despite their better engagement with HIV care services. The gains in adult life-years to date as well as the current LE deficit are almost exclusively due to differences in HIV and TB related mortality.



[Figure 1: Age-cause group contributions to the LE difference between the HIV neg. population and the population as a whole, by sex (2011-'14)]

## TUPEC133

### ANTIRETROVIRAL THERAPY (ART) AND HEAVY ALCOHOL USE IN HIV+ ADULTS IN THE MIAMI ADULT STUDIES IN HIV (MASH) COHORT IS ASSOCIATED WITH OXIDATIVE STRESS AND LIVER DAMAGE

M. Baum, S. Martinez, T. Stewart, Y. Li, C. Fleetwood, V. Ramamoorthy, A. Campa
*Florida International University, Miami, United States*
*Presenting author email: baumm@fiu.edu*

**Background:** Increased oxidative stress is implicated in the development of liver disease, a major cause of morbidity and mortality in HIV infection. While chronic alcohol and ART have been shown to increase oxidative stress and cytotoxicity in vitro, sufficient evidence is lacking in human populations.
Since the prevalence of alcohol use in people living with HIV (PLWH) is high, and the majority of HIV+ patients are on antiretroviral therapy (ART), it is important to study the interactions between alcohol consumption and ART and their effect on liver disease in PLWH.
**Methods:** PLWH from the MASH cohort (n=320) were consented. Questionnaires on demographics, ART use, and the Alcohol Use Disorders Identification Test (AUDIT) were completed ( ≥ 3 alcoholic drinks/day was defined as heavy alcohol drinking, < 3 alcoholic drinks/day was defined as moderate alcohol drinking/abstaining). Blood was drawn for measures of oxidative stress (mitochondrial-DNA-specific 8-oxo-dG [mt-8-oxo-dG]) and markers of liver function (AST, conjugated bilirubin, platelets). CD4 cell count and HIV viral load was obtained from medical charts. Descriptive and inferential statistics were used for analyses, adjusted for age, gender, BMI, CD4 cell count and HIV-viral load.
**Results:** Mean age was 44.9 ± 8.0 years, 65% were males and 69% were Black; 23% were heavy alcohol drinkers and 43% were not receiving ART. ART experienced participants had higher levels of oxidative stress and higher markers of liver disease than ART-naïve participants (higher mt-8-oxo-dG (ΔCt±SD) [β= 0.09 SE= 0.05; *P*=0.041]), higher AST (β=6.22, SE=3.06; *P*=0.044) and higher platelets (β=22.81, SE=11.57; *P*=0.05). Among the ART experienced, heavy alcohol drinkers compared to moderate drinkers/abstainers had higher mt-8-oxo-dG (β=0.09 SE= 0.05; *P*=0.041) and platelets (β=23.9, SE=11.7; *P*=0.044). These differences were not evident among the ART-naïve participants; however, heavy drinkers had higher AST (β=9.56 SE=4.8; *P*=0.050) and higher conjugated bilirubin (β=0.042, SE= 0.02; *P*=0.046).
**Conclusions:** These findings show that ART and alcohol are associated with oxidative stress and may exacerbate liver injury. These data provide the basis for future therapeutic approaches to protect the liver in HIV disease.

## TUPEC134

### TREND IN HIV/AIDS DEATHS IN SOUTH AFRICA: ARE WE WINNING THE BATTLE AGAINST HIV/AIDS?

V. Pillay-van Wyk[1], D. Bradshaw[1], W. Msemburi[1], R.E. Dorrington[2], R. Laubscher[3], P. Groenewald[1], Second National Burden of Disease Team
*[1]South African Medical Research Council, Burden of Disease Research Unit, Cape Town, South Africa, [2]University of Cape Town, CARE, Cape Town, South Africa, [3]South African Medical Research Council, Biostatistics Unit, Cape Town, South Africa Africa*

**Background:** South Africa is one of the countries most affected by the HIV/AIDS epidemic. Mortality estimates are a good indicator of the impact of prevention and treatment interventions. This paper compares mortality estimates for HIV/AIDS from the 2nd National Burden of Disease study for South Africa (NBD SA) and the Global Burden of Disease study for the country (GBD SA).
**Methods:** Vital registration cause-of-death data from Statistics South Africa were adjusted for under-reporting of deaths using demographic methods. Source causes with miss-attributed HIV/AIDS deaths were identified. A regression was performed to model the increase of age specific mortality for 1997 - 2003 against lagged HIV antenatal clinic prevalence to estimate mortality level without HIV/AIDS for these causes. These estimates were compared with HIV/AIDS estimates generated by the GBD study for the country.
**Results:** The NBD SA study estimates more HIV/AIDS deaths prior to 2005 (pre - treatment period) than GBD SA (Figure). HIV/AIDS deaths peaked in 2005/2006 in NBD SA and 2010/2011 in the GBD SA study. GBD SA underestimates deaths from HIV/AIDS for children < 5 years of age.
**Conclusions:** The GBD SA study overestimates HIV/AIDS deaths for South Africa post 2005 i.e. the antiretroviral treatment era and underestimates child deaths; an artefact of using a standardised model for all countries and UNAIDS Spectrum as a basis for their HIV/AIDS disease model. The downward turn in the number of HIV/AIDs deaths since 2005 in the NBD SA study align with the increase in access and coverage of antiretroviral treatment in the country and points to the success of HIV interventions.

### INTRODUCING A FOUR-POINT CONTINUUM FOR MONITORING THE EFFECTIVENESS OF THE HIV RESPONSE IN EUROPE AND CENTRAL ASIA

B. Rice[1], R. Drew[2], K. Attawell[3], D. Hales[4], A. Pharris[5], A. Amato-Gauci[5], T. Noori[5]
*[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]HIV Consultancy, Norwich, United Kingdom, [3]HIV Consultancy, London, United Kingdom, [4]HIV Consultancy, New York, United States, [5]European Centre for Disease Prevention and Control, Stockholm, Sweden*
*Presenting author email: brian.rice@lshtm.ac.uk*

**Background:** As part of monitoring the HIV response in Europe and Central Asia, the European Centre for Disease Prevention and Control (ECDC) undertook a scoping exercise to assess data availability to monitor the HIV continuum of care. Six elements of the continuum were investigated: number of people living with HIV (PLHIV), number diagnosed, linkage to care, retention in care, antiretroviral therapy (ART), and viral suppression.

**Methods:** In December 2013, ECDC forwarded questionnaires to nominated country representatives from 55 countries to study how they were monitoring the HIV care continuum. Representatives from 48 countries responded.

**Results:** Thirteen countries could provide data for all six elements of the continuum, while 32 could provide data for at least four. The study identified a lack of agreement as to what elements should be included in the continuum and how they should be defined. The elements least reported on, and with the least agreement on how to define, were 'linkage to' and 'retention in' care. Definitions of linkage to care varied from having attended HIV related care in a general or HIV specific health facility, having "registered" for care, or having had a CD4 count or viral load test. The time period within which these linkage to care markers were measured also differed. Definitions of retention in care included having at least one clinical visit per year, or having been in care over a defined period of time.

**Conclusions:** Attempts to compare HIV continuums across Europe and Central Asia are hampered by different data collection approaches and a lack of standard definitions. Based on feasibility to define common indicators and links to the UNAIDS 90:90:90 targets, ECDC is introducing a standardised four-point continuum (PLHIV; diagnosed; on ART; viral suppression) (figure 1). Separate measures will be used to monitor the remaining two quality of care elements as secondary outcomes.

[Figure 1: Monitoring a four-point continuum in Europe and Central Asia]

### TUPEC136

### THE USE OF A MATHEMATICAL MODEL AND RISK RATIO TO ESTIMATE THE IMPACT OF HIV/AIDS INTERVENTION PROGRAMS ON FEMALE SEX WORKERS (FSW) AND THEIR COMMUNITIES: THE NIGERIAN EXPERIENCE

S. Akwafuo[1], E. Mbanaso[2], D. Ogbang[3]
*[1]National Agency for the Control of AIDS (NACA), Abia State Liaison Office, Umuahia, Nigeria, [2]National Agency for the Control of AIDS (NACA), ART Services, Umuahia, Nigeria, [3]UNAIDS, Monitoring and Evaluation, Abuja, Nigeria*
*Presenting author email: sampson_akwa@yahoo.co.uk*

**Background:** The objective of the MMTWG is to develop a mathematical model to estimate how many indirect HIV infections will be inverted among FSWs, their clients and the general population, attributable to prevention programs targeting female sex works in Nigeria.

**Methods:** A mathematical model (as shown in the appendix) was developed, using python programming language. The variables include initial prevalence of HIV among FSW, their clients; proportion of sex acts that are protected; Initial population of the target group; duration of the intervention; number of sexual contacts per FSW and average number of sexual acts. A specific risk equation was developed for the FSW, incorporating the current values. Three Scenarios of the model was estimated over a period of five years. Putting all infected FSWs on treatment, irrespective of their CD4 or WHO staging and keeping other variables constant; Putting only eligible FSWs on treatment and increasing condom distribution; and universal access to treatment for all FSWs and their clients.

**Results:** It was observed that if the status quo (37% of eligible positive FSW on treatment) is maintained, the new infection rate will gradually increase to 3.6 in five years' time. Putting 80% of eligible positive FSWs on treatment will avert 2789 new infections in the same duration and reduce the current rate of new infections to 0.7. A slight decrease of 0.3% would be experienced in the general female population. Putting all FSWs on treatment returns a 89.7% reduction on the number of new infections among clients of FSW.

**Conclusions:** The mathematical model reveals the efficiency of treatment in reducing the rate of new infections among FSWs, their clients and general female. The models reveals the importance of the investing in the FSW intervention programs now, rather in the future. The model outputs can be used to calculate the Quality Adjusted Life Years (QALY) to be gained during the intervention. A slight contribution of the total number of condom distributed to a reduction in new infection rate was also noticed. Further modelling scenarios are required to effectively infer on the efficiency of the intervention programs.

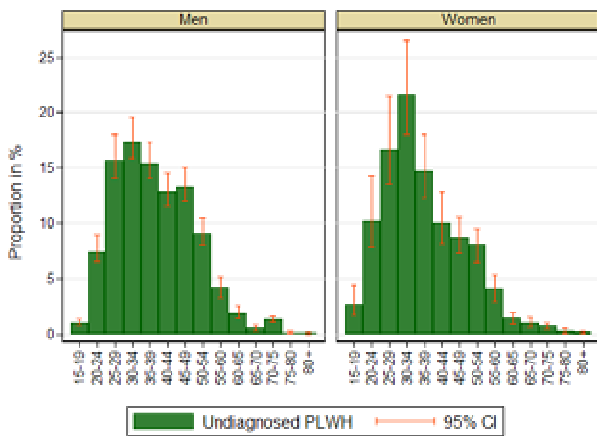
### TUPEC137

### UNDIAGNOSED HIV INFECTION IN GERMANY: WHO DO WE NEED TO TARGET?

M. an der Heiden, U. Marcus, B. Gunsenheimer-Bartmeyer, V. Bremer
*Robert Koch Institute, Dept. for Infectious Disease Epidemiology, Berlin, Germany*
*Presenting author email: bremerv@rki.de*

**Background:** People with undiagnosed HIV infection contribute to ongoing HIV transmission. We estimated the number of people with undiagnosed HIV infection in Germany by gender, transmission group and age in order to guide targeted intervention.

**Methods:** We corrected voluntary AIDS case reports (1982-1995) and statutory HIV notification (1993 onwards) for underreporting and used a monotone multiple imputation model to complete missing values. We used a combined non-parametric back projection model of AIDS cases and HIV diagnoses by gender and transmission group with age-group and CD4 cell count group as covariates. The number of undiagnosed infections in non-Germans acquired abroad could not be estimated, because migration disturbed the association between the number of infections and diagnoses.
**Results:** At the end of 2014, around 83,000 (77,000-91,200) people were living with HIV in Germany. Of these, around 13,200 (12,100-14,700; 15.9%) were undiagnosed. Most undiagnosed infections were among men (10,900; 10,100 - 12,100). Men who have sex with men (MSM) would be the largest group of undiagnosed (9,600; 8,900 - 10,600), followed by persons with heterosexual contacts (HET; 2700; 2300 - 3200) and drug users (IDU; 860; 650 - 1300). Conversely, the proportion of undiagnosed infections was the highest in HET (25.5%), followed by MSM (17.9%) and IDU (10.8%). Most affected age-groups of undiagnosed infections were 25-49 years in men and 25-39 years in women (Figure 1).



*[Age and sex distribution of undiagnosed people living with HIV (PLWH) in Germany 2014]*

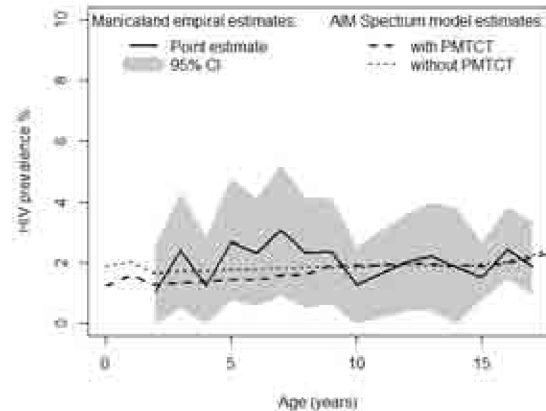
**Conclusions:** A substantial proportion of people living with HIV are still undiagnosed in Germany. Since the model could not take into account infections in non-Germans acquired abroad, the actual number of undiagnosed infections may be larger. To decrease this proportion, barriers to testing should be reduced, i.e. by reducing stigma, testing campaigns targeting MSM and HET or selling home testing/home collection tests. These interventions should not only be targeted at young adults, as many undiagnosed infections are estimated among middle-aged men.

## TUPEC138

### CAN UNAIDS' SPECTRUM (AIM) MODEL PROVIDE RELIABLE LOCAL ESTIMATES FOR CHILDREN AFFECTED BY HIV IN EAST ZIMBABWE?

R. Silhol[1], S. Gregson[1,2], C. Nyamukapa[1,2], M. Mhangara[3], J. Dzangare[3], J. Eaton[1], K. Case[1], M. Mahy[4], P. Ghys[4], J. Stover[5], O. Mugurungi[3]
*[1]Imperial College London, Infectious Disease Epidemiology, London, United Kingdom, [2]Biomedical Research and Training Institute Avondale, Harare, Zimbabwe, [3]AIDS and TB Unit, Zimbabwe Ministry of Health and Child Welfare, Harare, Zimbabwe, [4]UNAIDS, Geneva, Switzerland, [5]Avenir Health, Glastonbury, United States*
*Presenting author email: s.gregson@imperial.ac.uk*

**Background:** Reliable estimates of HIV and its effects in children are needed to establish the coverage and effectiveness of prevention and ART programmes amongst children. The AIDS Impact Model (AIM) in Spectrum is used by countries, with UNAIDS support, to produce HIV estimates but should be evaluated with empirical data. Using a region-specific model, we compare AIM estimates of HIV prevalence and orphanhood with general population data from Manicaland, east Zimbabwe.
**Methods:** Antenatal surveillance (ANC) data (N≈1200 per round) and population survey data (N≈10,000) for adults aged 15-49 years, from 12 sites in 3 districts in Manicaland, east Zimbabwe, collected in 5 rounds between 1998 and 2011, were input into AIM 2016 (version 5.40, February 2016, available at http://www.avenirhealth.org) to create a region-specific simulation on a consistent basis with national estimates. The simulation was fitted to local ANC surveillance and general-population data on HIV prevalence in adults. The model outputs were compared with empirical survey estimates of HIV and orphan prevalence in children aged 2-14 years, and 2010 Manicaland provincial DHS data on orphanhood. The impact of PMTCT services until 2010 (mainly single dose nevirapine) was assessed by comparing these model estimates with those from a model assuming no PMTCT coverage.



*[Figure 1. HIV prevalence among children in 2010]*

**Results:** The AIM model predicted a prevalence of 1.7% among children aged 2-14 in 2010, compared to the observed prevalence 2.2% (95% CI: 1.7-2.6%) in the Manicaland survey. The estimated impact of PMTCT services on HIV prevalence in children was modest but significant amongst newborns, with a 33% relative reduction (Figure 1).
Paternal orphanhood was lower than both survey and DHS estimates, whereas maternal orphanhood was higher than the two estimates until 2005, then slightly lower.
**Conclusions:** The most recent AIM model, parameterised using local population data, provided reasonable estimates of HIV prevalence in children but some differences were found in orphanhood prevalence.

# RISK FACTORS FOR ACQUISITION OF HIV

## TUPEC139

### DO ADULTS MODIFY FREQUENCY OF CONDOM USE IF THEY SUSPECT THEIR PARTNER IS HIV-POSITIVE? FINDINGS FROM A NATIONAL HOUSEHOLD SURVEY IN SWAZILAND

M. Simelane[1], B. Nsibandze[2], Z. Nxumalo[2], N. Shongwe[2], S. Masuku[2], W.W. Dlamini[2], B. Dlamini[2], G. Dube[2], Y. Wu[3], S. Sithole[2], T. Ao[2,4], H. Kamiru[1,2], P. Dlamini[2], F. Dlamini[2], T. Ntshakala[2], R. Nkambule[5], R. Sahabo[1], J. Justman[3], H. Nuwagaba-Biribonwoha[1,2]
*[1]ICAP, Columbia University, Mailman School of Public Health, Mbabane, Swaziland, [2]Health Research Training Program (HRTP), Mbabane, Swaziland, [3]ICAP, Columbia University, Mailman School of Public Health, New York, United States, [4]US Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV/AIDS, Mbabane, Swaziland, [5]Ministry of Health, Mbabane, Swaziland*
*Presenting author email: jj2158@cumc.columbia.edu*

**Background:** Inconsistent condom use could contribute to high HIV incidence in generalised epidemics. HIV prevalence among adults 18-49 years in Swaziland is estimated at 32%. We assessed whether adults modified consistency of condom use if they suspected their partner was HIV positive.
**Methods:** A secondary analysis of the 2011 Swaziland HIV incidence Measurement Survey (SHIMS) was conducted. SHIMS was a nationally representative cross-sectional household survey of 18,172 adults 18-49 years. Participants reporting sexual activity in the previous 6 months were asked if they thought any of their 3 most recent partners was HIV positive or negative, and if they used condoms with these partners always, or inconsistently (sometimes or never). We used multivariable logistic regression to determine correlates of inconsistent condom use with a suspected HIV positive partner.
**Results:** Of 13,971 adults reporting sexual activity (57% female, 43% male), 2,265 (16%) reported sex with a partner they thought was HIV positive, 1,344 (9.6%) of whom reported inconsistent condom use. The majority, 8,251 (59%) reported sex with a partner they thought was HIV negative, of whom 5,911 (42%) reported inconsistent condom use. Higher odds of inconsistent condom use with a suspected HIV positive partner were observed among females, adjusted odds ratio, AOR (95% Confidence Interval): 1.2 (1.1, 1.4). Regionally, the practice was more common in Manzini AOR 1.2 (1.1, 1.4) and less common in Lubombo AOR 0.7 (0.6, 0.8), reference: Hhohho. Higher odds were observed among those with primary education, AOR 1.3 (1.1, 1.5), reference: tertiary education; among single adults AOR 1.3, (1.1, 1.5), reference: adults married and living with partner; and among adults with sexual debut at 14 -16 years of age AOR 1.4 (1.1, 1.7), reference: sexual debut at ≥22 years. Residing in an urban area was associated with lower odds AOR 0.8 (0.7, 0.9), reference: rural area.

**Conclusions:** Condoms were inconsistently used even when adults suspected their partner was HIV positive. Reasons for this warrant exploration with qualitative studies. Suspicion of partner HIV exposure seemed low in this high prevalence setting, definitive determination of partner HIV status through partner testing and disclosure should be encouraged.

## TUPEC140

### AGE-MIXING PATTERNS AND HIV TRANSMISSION IN THE LIKOMA NETWORK STUDY

R. Beauclair[1,2], S. Helleringer[3], N. Hens[4,5], W. Delva[1,2,4]
*[1]Stellenbosch University, DST/NRF Centre for Excellence in Epidemiological Research (SACEMA), Stellenbosch, South Africa, [2]Ghent University, International Centre for Reproductive Health, Gent, Belgium, [3]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [4]Hasselt University, Centre for Statistics, Diepenbeek, Belgium, [5]University of Antwerp, Centre for Health Economic Research and Modeling Infectious Diseases, Wilrijk, Belgium*
*Presenting author email: roxanne.beauclair@gmail.com*

**Background:** It has been suggested that the age-mixing pattern (AMP) in a population may partially explain the magnitude of HIV epidemics observed in Sub-Saharan Africa. Currently, there is conflicting evidence about whether a woman's choice of older sex partners puts her at increased risk of HIV infection. We aim to describe the AMP in the Malawian context and its relationship to participants' HIV status.
**Methods:** We conducted an analysis from the 2007/2008 implementation of the Likoma Network Study, a sociocentric network study of sexual behaviour and HIV on Likoma Island, Malawi. The AMP was visualised using scatterplots of participant age versus partner age. We used generalized linear mixed effects models to quantify the AMP in more detail, and to find associations between relationship characteristics and age-difference (AD). Logistic regression models were used to estimate the relationship between maximum AD and HIV status, adjusting for age and number of partners.
**Results:** The women (n= 1068) and men (n= 854) in our study reported 1648 and 1688 relationships, respectively. Among both genders there is a positive linear relationship between age of participant and partner's ages. The slope of the regression line in the male model is 0.72, while in the female model it is 1.1, indicating a slightly sharper increase in average partner age as women get older. For men and women, having a relationship with a non-spousal partner and using condoms in their relationship was predictive of smaller ADs. Men who said their female partners had a concurrent relationship, had on average a one-year increased AD compared to those who did not (95% CI: 0.15-1.89). Among women, those who had a partner at least 10-14 years older than them, were nearly 2 times more likely to be HIV positive than those whose maximum AD was 0-4 years (95% CI: 1.04-3.56).
**Conclusions:** This study shows that as women get older, they choose increasingly older partners. It also provides some evidence that large ADs between a woman and her partner may convey a higher risk for acquiring HIV. This may be the result of women and men using condoms less often in relationships where ADs are greater.

## TUPEC141

### FACTORS ASSOCIATED WITH ACQUISITION OF HIV DURING 2005-2014 AMONG MEN AND WOMEN IN 7 COHORTS THAT PARTICIPATE IN THE NETWORK FOR ANALYSING LONGITUDINAL POPULATION-BASED HIV/AIDS DATA ON AFRICA (ALPHA)

E. Slaymaker[1], C. Calvert[1], E. McLean[2,3], D. Gareta[4], C. Kanjala[3,5], I. Kasamba[6], D. Nabukalu[7], M. Sewe[8], A. Takaruza[9], B. Zaba[1], M. Marston[1], A.L.N. Dube[2], S. Gregson[10]

*Presenting author email: emma.slaymaker@lshtm.ac.uk*

**Background:** Correlates of incident HIV infection may change as epidemics mature, treatment becomes widespread and behaviour changes. In seven rural study sites from Kenya, Malawi, South Africa, Tanzania, Uganda and Zimbabwe, ART has been available for at least 8 years. We examine factors associated with incidence among men and women aged 15 to 49 in these populations.
**Methods:** We analysed longitudinal data from seven population-based cohorts with regular HIV testing to ascertain factors associated with incident infection subsequent to ART rollout (2005-2014).
Analysis time begins at the first negative HIV test and ends at seroconversion or is right censored by death, out migration or the end of data collection. We estimated HIV incidence rates (IR) and fitted piecewise exponential models to survival time to estimate hazard ratios (HR) for HIV incidence.
**Results:**

| Explanatory variables | Men: Crude HIV incidence/100 person years | Women: Crude HIV incidence/100 person years | Men: Adjusted HR (N 22,154) | Women: Adjusted HR (N 31,028) |

*[Table 1. HIV IR by selected factors and results from exponential regression models for men and women. *** p<0.001 ** p<0.01 *p<0.05]*

Peak age-specific IRs were at ages 20-24 (women) and 25-29 (men). Adjusted for site, marital status, mobility and calendar year, the hazard of infection remained stable until age 35 for both sexes.
Crude IRs were lower for person-time spent married compared to unmarried. Adjusted HRs showed a protective effect of marriage for women of all ages but, for men under 25, marriage increased the hazard of HIV infection compared to single men (Table 1). In the regression model, older men's marital status was not associated with incidence.
The six months either side of a change of residence were associated with higher hazard of infection for women but not men (Table 1).
Date on circumcision and sexual behaviour await analysis.
**Conclusions:** Factors associated with incidence in these populations differ between men and women. Marriage is a risk for young men and protective for young women. For women, a change in residence, which presents a risk, may coincide with getting married, and thus reduce the observed benefit of marriage. For men aged over 25, marriage does not lower the hazard of infection, perhaps due to extra-marital sex.

## TUPEC142

### EXECUTIVE FUNCTIONING ASSOCIATED WITH HIV RISK BEHAVIORS IN YOUNG SOUTH AFRICAN WOMEN

M. Rosenberg[1], A. Pettifor[2], M. Duta[3], R. Wagner[4], A. Selin[5], C. MacPhail[6], O. Laeyendecker[7], J. Hughes[8], S. Tollman[4], K. Kahn[4]
*[1]Harvard University, Center for Population and Development Studies, Cambridge, United States, [2]University of North Carolina - Chapel Hill, Epidemiology, Chapel Hill, United States, [3]University of Oxford, Experimental Psychology, Oxford, United Kingdom, [4]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Johannesburg, South Africa, [5]University of North Carolina - Chapel Hill, Carolina Population Center, Chapel Hill, United States, [6]University of New England, School of Health, Armidale, Australia, [7]Johns Hopkins University, School of Medicine, Baltimore, United States, [8]University of Washington, Biostatistics, Seattle, United States*
*Presenting author email: mrosenb@hsph.harvard.edu*

**Background:** Heightened sexual risk-taking in adolescence may be partially explained by the ongoing cognitive development that occurs during this period. However, the association between cognitive functioning and adolescent HIV risk is understudied, particularly in developing country contexts.
**Methods:** We evaluated executive functioning in a cohort of 853 young women age 18-25 in rural Mpumalanga province, South Africa who were enrolled in the HIV Prevention Trial 068 in a follow-up visit after trial exit. We administered two tests designed to be used in non-Western settings with minimal language reliance: a task switching test (Test 1) and a rule finding and switching test (Test 2). Using log-binomial regression models, we estimated the association between scoring in the lowest quintile of each executive function test and several behavioral (unprotected sex acts, concurrent partnerships, transactional sex) and biological (prevalent HSV-2 infection) indicators of HIV risk.
**Results:** In general, young women who tested in the lowest quintile of executive functioning reported higher levels of HIV risk behaviors and had higher HSV-2 prevalence, though associations tended to be small with wide confidence intervals. In particular, testing in the lowest quintile of Test 1 was associated with more concurrent relationships and more transactional sex [aPR (95% CI): 1.54 (1.02, 2.32) and 1.65 (1.22, 2.23), respectively]. Testing in the lowest quintile of Test 2 was associated with more reports of unprotected sex acts [aPR (95% CI): 1.35 (1.03, 1.77)].
**Conclusions:** These results demonstrate an association between low executive functioning and adolescent HIV risk. Future work should seek to better understand the relationship between cognitive functioning and adolescent HIV risk, with attention to disentangling the directionality of the relationships, and to exploring associations across different cognitive domains. If confirmed, these findings suggest that targeted interventions to increase cognitive function could provide a new tool for HIV risk reduction.

*[Figure 1. The association between testing in the bottom quintile of two executive functioning tests and four behavioral indicators of HIV risk, among 853 young women in rural South Africa]*

## TUPEC143

### TIME-VARYING BEHAVIORAL RISK FACTORS ASSOCIATED WITH HIV ACQUISITION IN MEN WHO HAVE SEX WITH MEN (MSM) AND TRANSGENDER WOMEN (TGW) IN LIMA, PERU. DATA FROM THE *¿SABES?* COHORT STUDY

A. Ulrich[1,2], J. Lama[3], H. Sanchez[4], R. Cabello[5], A. Duerr[1,2]
*[1]Fred Hutchinson Cancer Research Center, Seattle, United States, [2]University of Washington, Seattle, United States, [3]Impacta, Lima, Peru, [4]Epicentro, Lima, Peru, [5]Via Libre, Lima, Peru*
*Presenting author email: aulrich@fhcrc.org*

**Background:** Identification of modifiable risk factors for HIV acquisition can help guide prevention strategies that are urgently needed for MSM and TGW in Lima, Peru, among whom HIV prevalence is >20%. Using data from a cohort study of incident HIV infection, this study seeks to examine both baseline and time-varying predictors of HIV acquisition.
**Methods:** Between July 2013 and October 2015, 3,191 MSM and TGW who were unaware of their HIV status were screened for participation in a 24-month cohort study. HIV prevalence among those screened was 20.5%. HIV-uninfected volunteers (N=2,078) were tested monthly for incident HIV with point-of-care 3rd generation HIV EIA; seronegative specimens were then tested for HIV RNA (HIV incidence=8.6% per year). Monthly questionnaires measured risk behavior in the past 30 days, covering the period of HIV acquisition for incident cases. Risk factors included sexual activity, drug/alcohol use, social venue attendance (e.g. bars, saunas), and sexual encounters with a partner met at a venue. Predictors of HIV acquisition were assessed using multivariate survival analysis with time-constant and time-varying covariates.
**Results:** The strongest predictor of HIV acquisition was sexual role: receptive and versatile partners were more likely to acquire HIV compared to insertive partners (HR=2.69, p=0.001; HR=3.21, p<0.001, respectively). Commercial sex within 30 days of diagnosis was also associated with HIV acquisition (HR=1.33, p=0.065), yet sex worker status assessed at baseline was not a risk factor. Non-sex workers and those who exchanged sex for food, shelter, drugs, etc. were more likely to acquire HIV than those who self-identified as sex workers at study enrollment (HR=2.40, p=0.006; HR=1.79, p=0.107, respectively). After adjustment for drug and alcohol use, time-varying measures associated with incident HIV were sexual encounters with partners met at a venue (HR: 1.47, p< 0.001), and marijuana use before or during sex (HR=1.49; p=0.075).
**Conclusions:** Sexual encounters with partners met at social venues, a time-varying measure of risk, was strongly associated with HIV acquisition, demonstrating the need for increased HIV prevention activities at high-risk venues in Lima. Furthermore, this study indicates that analyses which incorporate time-varying exposures may more accurately identify risk factors for HIV.

## TUPEC144

### GENITAL HSV-2 SHEDDING IN PREGNANCY AND POST-DELIVERY: IMPLICATIONS FOR HIV ACQUISITION IN WOMEN AND MOTHER TO CHILD TRANSMISSION OF HIV

D. Moodley[1], S. Maman[2], L. Madurai[3], P. Moodley[4], B. Sartorius[4]
*[1]University of KwaZulu Natal, Obstetrics and Gynaecology, Durban, South Africa, [2]University of North Carolina, Department of Health Behaviour, Chapel Hill, United States, [3]Global Clinical and Viral Laboratory, Durban, South Africa, [4]University of KwaZulu Natal, Durban, South Africa*
*Presenting author email: moodleyd1@ukzn.ac.za*

**Background:** A recently published meta-analysis representing 22 803 person years, and two studies in South Africa concluded that women continue to be at risk for HIV infection in pregnancy and postdelivery and the risk of mother-to-child transmission (MTCT) was higher among pregnant women with incident infections. A recent South African HSV-2 serosurvey irevealed that more than 80% of HIV+ pregnant women in South Africa are seropositive for HSV-2. The study aims were to investigate genital HSV-2 shedding in a cohort of women during pregnancy and postpartum and identify determinants for HSV-2 shedding..
**Methods:** Between 2008-2010 antenatal attendees who participated in a behavioural study, were tested for HIV and other STIs (*N. gonorrhoeae*, *C. trachomatis* and *T. vaginalis*) at the first antenatal visit and 14 weeks postpartum. Investigations included collection of a vulvo-vaginal specimen (swab). Crude extracts of DNA remaining after PCR testing for *N. gonorrhoeae, C. trachomatis* and *T. vaginalis* were stored at -70 degrees celcius. These DNA extracts were recently tested for HSV1/2 DNA using the Light Cycler HSV1/2 Detection Kit Light Mix Kit Roche Diagnostics , USA .
**Results:** The HIV seroprevalence in this cohort of pregnant women was 36.6% and 342 HIV- women were retested for HIV prior to or post delivery. There were 5 incident cases of HIV over a cumulative period of 157.37 years. HIV incidence in pregnancy being 3.18/100wy (95% CI 1.03-7.41).
Genital HSV-2 shedding was prevalent in 51/615 women in pregnancy (8.29%; 95%CI 6.29-10.83) and 15/511 women postpartum (2.94%; 95%CI 1.71-4.91). HIV+

women were 2.3 times more likely to test positive for HSV-2 shedding than HIV- women (11.56% vs 6.25% in pregnancy and 3.95%vs1.51% postpartum, p=0.022). Age, gravidity, socio-economic status, or any of the other sexually transmitted diseases were not associated with genital HSV-2 shedding. Only one of the 5 (20%) incident cases of HIV was positive for genital HSV-2 shedding postpartum..
**Conclusions:** We confirm a strong association between HIV and HSV-2 in pregnant women. A larger study is needed to determine if HSV-2 shedding increases the risk for MTCT in HIV+ pregnant women and risk of HIV acquisition in HIV- pregnant and postpartum women.

## RISK FACTORS FOR INFECTIVITY, PROGRESSION AND TRANSMISSION OF HIV

## TUPEC145

### PREDICTORS OF PROGRESSION FROM HIV-INFECTION TO AIDS AND AIDS-RELATED MORTALITY: A 11-YEAR PROSPECTIVE COHORT STUDY IN TIANJIN, CHINA

M. Yu[1], N. Zhou[1], Y. Guo[1], Z. Liu[1], X. Dong[1], S. Cheng[1], T. Ning[1], M. Zheng[1], J. Xu[2], G. Jiang[1]
*[1]Tianjin Center for AIDS/STD Control and Prevention, Tianjin Center for Disease Control and Prevention, Tianjin, China, [2]Chinese Center for Disease Control and Prevention, National Center for AIDS/STD Control and Prevention, Beijing, China*
*Presenting author email: fish820225@sina.com*

**Background:** The objective of this study was to identify specific factors associated with progression of acquired immunodeficiency syndrome (AIDS) and mortality in patients with human immunodeficiency virus (HIV)/AIDS. This prospective cohort study study was conducted in Tianjin, China from from January 2004 to December 2014.
**Methods:** Disease progression data from the diagnosis of HIV infection or acquiring immunodeficiency syndrome (AIDS) were collected from the national surveillance system databases and the national treatment database in Tianjin, China. Kaplan-Meier method, and Cox proportional hazards model were applied to identify the related factors of progression to AIDS or death following HIV diagnosis.
**Results:** We enrolled 3177 HIV-infected individuals or AIDS patients in Tianjin Centers for Disease Control and Prevention. The outcomes of interest were the estimation of time:
(1) from HIV diagnosis to AIDS progression and
(2) from AIDS to AIDS-related death.
The 1st-year, 5th-year, and 9th-year probability for disease progression from HIV diagnosis to AIDS was 6.9%, 8.9% and 2.4%, and that for AIDS-related death was 13.9%, 10.4%, and 5.0%, respectively. Multivariate Cox regression analysis indicated that AIDS progression was significantly associated with age (*P* = 0.013), HARRT or not (*P* = 0.000), and baseline CD4 count (*P* = 0.000). HIV-infectors aged between 31-50 years old were more likely to progress to AIDS and a low CD4 count was correlated with an increased risk progression to AIDS. Furthermore, the AIDS-related mortality was significantly associated with age (*P* = 0.000), transmission category (*P* = 0.007), HARRT or not (*P* = 0.000), and baseline CD4 count (*P* = 0.000). The transmission of HC (HR, 1.854 (95%CI: 1.296, 2.626)) and blood (HR, 2.610 (95%CI: 1.127, 6.045)) were predictors of higher mortality of AIDS-related death.
**Conclusions:** The results of this study indicated that progression to AIDS and AIDS-related death is affected by several modifiable and non-modifiable predictors. Initiation of HAART with higher CD4+ T-cell count may reduce rate of AIDS progression. Based on our results, we conclude that efficient strategies for HIV screening, as well as early diagnosis and treatment are necessary to reduce the progression of HIV to AIDS.

## TUPEC146

### GEOGRAPHIC HIV EPIDEMIC MAPPING: A STRATEGY FOR IDENTIFYING POPULATIONS AT HIGH-RISK OF HIV INFECTION IN ZIMBABWE

O. Tapera[1,2], M. Munjoma[1], M. Mapingure[1], B. Mutedzi[1], V. Mutoma[1], V. Zambuko[1], S. Gudukeya[3], K. Hatzold[4]
*[1]PSI Zimbabwe, Research, Metrics and Information Systems, Harare, Zimbabwe, [2]Midlands State University, Applied Mathematics, Gweru, Zimbabwe, [3]PSI Zimbabwe, Health Services, Harare, Zimbabwe, [4]PSI Zimbabwe, Harare, Zimbabwe*
*Presenting author email: oscar.tapera@gmail.com*

**Background:** Zimbabwe is one of the countries in sub-Saharan Africa most affected by HIV, with a prevalence rate of 15.2% according to ZDHS (2011). Geographical structure of the epidemic is influenced by some driving factors and it has implications on the susceptibility of infection amongst some populations. PSI Zimbabwe embraced the universal 90-90-90 concept and it endeavours to reduce HIV transmission by targeting populations with high positivity in Zimbabwe. PSI Zimbabwe employs targeted mechanism during outreach HIV Testing Services (HTS) to increase chances of reaching HIV positive clients.
This study was aimed at identifying geographic clusters of HIV based on positivity threshold of 10% countrywide.
**Methods:** Routine data from the outreach HTS programme administered by PSI Zimbabwe's New Start Centre network and collected between October and December 2015 was used for this analysis. A database with a total of 68,577 clients was used for this study. Geographic coordinates for places were outreach activities took place were used for analysis. Sixty-five (65) districts where the outreach HIV testing and counselling services were provided were considered as the geographic epidemic clusters for the analysis, by classifying them according to HIV positivity based on the 10% threshold.
**Results:** The average HIV positivity was 9.1% nationally. Fifteen out of 65 (23%) districts were identified as having areas with HIV positivity equal or greater than 10%. Thirty three percent of clients were first time testers. Four districts (6%) had areas with HIV positivity greater 15%. Results suggest geographic variation in the transmission of HIV in Zimbabwe.
**Conclusions:** This study provides evidence of HIV geographic clustering. The findings identify priority geographic areas for HIV programming and support the need for targeted interventions amongst populations at high risk in order to achieve the desired 90-90-90 targets by 2020.

## EPIDEMIOLOGY OF HIV IN THE GENERAL POPULATION

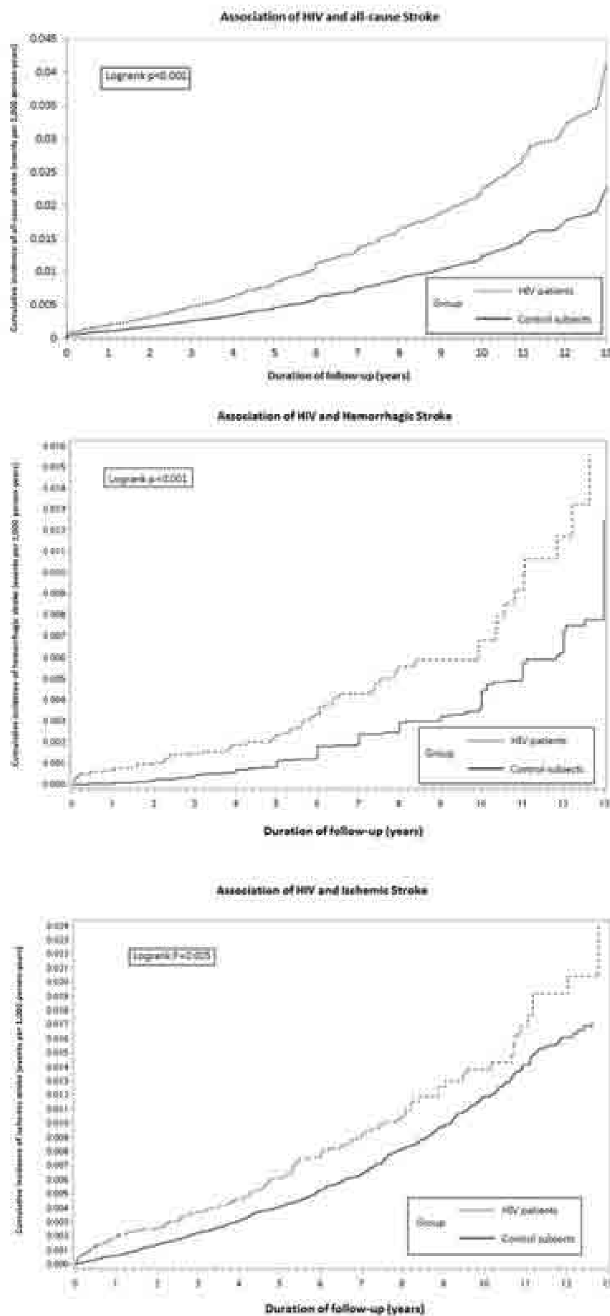
## TUPEC147

### ASSOCIATION OF HIV AND OPPORTUNISTIC INFECTIONS WITH INCIDENT STROKE: A NATIONWIDE POPULATION-BASED COHORT STUDY

Y. Yen[1,2], I. Jen[3], Y.-M.A. Chen[4,5]
*[1]Taipei City Hospital, Section of Infectious Diseases, Taipei County, Taiwan, Province of China, [2]National Yang-Ming University, School of Medicine, Taipei, Taiwan, Province of China, [3]National Yang-Ming University, Department and Institute of Public Health, Taipei, Taiwan, Province of China, [4]Kaohsiung Medical University, Center for Infectious Disease and Cancer Research, Kaohsiung, Taiwan, Province of China, [5]Kaohsiung Medical University, Department of Microbiology and Institute of Medical Research, College of Medicine, Kaohsiung, Taiwan, Province of China*
*Presenting author email: dam37@tpech.gov.tw*

**Background:** HIV virion may cause endothelial dysfunction and atherosclerosis. Also, a series of case reports showed that opportunistic infections (OIs) [e.g., cryptococcal meningitis, cytomegalovirus, or *Candida albicans* infection] in HIV patients may lead to stroke development. However, few longitudinal studies have examined the association of HIV and OIs with subsequent development of stroke. This nationwide cohort study aimed to evaluate the association of HIV and OIs with incident stroke.
**Methods:** From Jan. 1, 2000, we identified 21,375 adult HIV patients (ICD-9-CM code 042-044, 7958, or V08) from the Taiwan National Health Insurance Research Database. 85,500 controls without HIV infection, matched for age and sex, was selected for comparison. All patients were followed until a diagnosis of stroke, death, or December 31, 2012. The outcome new stroke was defined as ICD-9-CM codes 430-437. The time-dependent analysis was used to determine the association of HIV and OIs with incident stroke.
**Results:** Of the 106,875 patients, stroke occurred in 927 patients (0.87%) during the 581,580 person-years of follow-up. After adjusting for age, sex, and comorbidities, HIV infection was an independent risk factor for incident all-cause stroke [ad-

justed hazard ratio (AHR) 1.83; 95% confidence interval (CI) 1.58-2.13]. When type of stroke was considered, HIV infection increased the risks of ischemic (AHR 1.33; 95% CI 1.09-1.63) and hemorrhagic stroke (AHR 2.01; 95% CI 1.51-2.69). The risk of incident stroke was significantly higher in HIV patients with cryptococcal meningitis (AHR 4.40; 95% CI 1.38-14.02), cytomegalovirus disease (AHR 2.79; 95% CI 1.37-5.67), and Penicillium marneffei infection (AHR 2.90; 95% CI 1.16-7.28).



*[Kaplan-Meier Curves for Time to Diagnosis of Incident Stroke in Patients with and without HIV Infection]*

**Conclusions:** This suggested that HIV infection was an independent predictor of ischemic and hemorrhagic stroke. To reduce the risk of stroke, comprehensive care should be provided to HIV patients, particularly those with cryptococcal meningitis, cytomegalovirus, or *P. marneffei* infection.

## TUPEC148

### META-ANALYSIS SHOWS BIASED ESTIMATES OF DEATH IN HIV-POSITIVE ADULTS ON ART IN LMIC

A. Brennan[1,2,3], H. Useem[1], L. Garrison[2], L. Long[3], M.P. Fox[1,2,3]
*[1]Boston University, Department of Epidemiology, Boston, United States, [2]Boston University, Department of Global Health, Boston, United States, [3]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Johannesburg, South Africa*
*Presenting author email: llong@heroza.org*

**Background:** Loss to follow-up is a common problem in epidemiological studies. HIV-positive patients in low-to-middle income countries (LMICs) are at highest risk of poor retention in care, death and loss, in the first 3-months on antiretroviral therapy(ART).
We systematically reviewed studies of mortality in the first 3-months post-ART initiation in LMIC and classified studies based on the potential for bias.
**Methods:** Studies of mortality within 3-months post-ART initiation from January 2003-October 2014 in PubMed, Web of Science, EMBASE and IAS and AIDS abstracts were searched. Articles were included if they were conducted in a LMIC; a non-trial setting; participants were ≥15 and reported 3-month mortality. Using random effects models we assessed 3-month mortality overall and stratified by study bias. Low bias was assigned if a study specified active and passive tracing of patients lost, moderate bias if specified passive tracing and high bias if no mention of either.
**Results:** 54 studies were included; 43 (78%) from SSA, 10 (19%) from Asia, 1 (2%) from the Americas. Overall 3-month mortality was 5.9% (95% CI: 5.1-6.8%). When stratified by level of study bias, mortality estimates were higher for studies reporting active and passive tracing (low bias:7.4%; 95%CI: 6.1-8.8%) vs. those only mentioning passive tracing (moderate bias:5.4%; 95%CI: 3.9-7.2%) or those mentioning neither active or passive tracing (high bias:3.7%; 95%CI: 3.5-4.0%)
**Conclusions:** Our results show that estimates of early mortality in LMIC countries are underestimated by 30-50% due to potentially undercounting deaths and loss to follow-up bias, supporting previous studies.
Linking to vital registration systems, whenever possible, and active tracing of patients lost could result in more valid estimates of early mortality and help those loss return to care and decrease their risk of death. As smaller decentralized ART facilities increase in number, rates of retention in the early stages of HIV care and treatment should improve.

## TUPEC149

### COMBINED ANTIRETROVIRAL THERAPY AND ARTERIAL STIFFNESS IN HIV-INFECTED PATIENTS FROM A BRAZILIAN COHORT

R.C. Moreira[1,2], A.G. Pacheco[1], B. Grinsztejn[2], M.D.J. Fonseca[3], R.I. Moreira[2], V.G. Veloso[2], M. Santini Oliveira[2], S.W. Cardoso[2], J.G. Mill[4], I. Bensenor[5], R.H. Griep[6], P. Lotufo[5], D. Chor[3]
*[1]Fiocruz, Programa de Computação Científica, Rio de Janeiro, Brazil, [2]Fiocruz, Instituto de Pesquisa Clínica Evandro Chagas, Rio de Janeiro, Brazil, [3]Fiocruz, Departamento de Epidemiologia e Métodos Quantitativos em Saúde, Rio de Janeiro, Brazil, [4]Federal University of Espírito Santo, Departamento de Ciências Fisiológicas, Espírito Santo, Brazil, [5]University of São Paulo, School of Medicine, São Paulo, Brazil, [6]Fiocruz, Laboratório de Educação em Ambiente e Saúde, Rio de Janeiro, Brazil*
*Presenting author email: rodrigo.moreira@ini.fiocruz.br*

**Background:** Evidence suggests that combined antiretroviral therapy (cART) is associated with increased arterial stiffness measured by carotid-femoral pulse wave velocity (cf-PWV) in HIV-infected population. We aimed to assess if cART use and specific regimens are associated with arterial stiffness compared to cART-naive patients.
**Methods:** Cf-PWV was determined in 536 HIV infected patients followed in the Instituto de Pesquisa Clínica Evandro Chagas (IPEC) using a validated automated device (Complior SR, France). Arterial stiffness (AS) was considered when the cf-PWV was greater than 75th percentile. Linear regression analyses with logarithmic transformation of cf-PWV were performed to adjust differences between cART use, including specific regimens and factors associated to arterial stiffness.
**Results:** Overall, 58.46% of participants were male, median age was 43.58 (interquartile range (IQR) 36.57-50.18 years). AS was present in 33.3% of participants, 89.16% of them using cART for a median of 4.15 (IQR: 0.7-10.17) years and 71% with undetectable viral load. Patients with AS were older and more likely to have traditional cardiovascular risk factors, lipid profile and time on cART when compared to those without AS.

| Arterial Stiffness | Yes | No | Total | p-value |
|---|---|---|---|---|
| Total | 402 | 134 | 536 | |
| Male | 235 (58.46) | 70 (52.24) | 305 (56.9) | 0.24 |
| Age Median (IQR) | 41.46 (35.06-46.83) | 50.85 (45.76-57.45) | 43.58 (36.57-50.18) | <0.001 |
| Smoking 10+ packs-year | 98 (24.44) | 47 (35.07) | 145 (27.1) | 0.02 |
| Hypertension | 89 (22.14) | 74 (55.22) | 163 (30.41) | <0.001 |
| Diabetes | 78 (19.4) | 48 (35.82) | 126 (23.51) | <0.001 |
| Dyslipidemia | 137 (34.77) | 66 (49.25) | 203 (38.45) | 0.004 |
| Baseline CD4 counts (cells/mL) | 531 (337.5,709.5) | 593.5 (413.25,813.75) | 540 (362.5,738.5) | 0.004 |
| cART use | 352 (87.56) | 125 (93.98) | 477 (89.16) | 0.05 |

*[Descriptive statistics and comparisons between HIV-infected patients according to arterial stiffness]*

After adjusting for age, DBP, BMI, hypertension, medication for hypertension and smoking, cART was not associated with AS compared to cART-naive participants but there was a significant difference in AS among patients after 12 and 15 years of cART and Protease Inhibitor (PI) use respectively (p< 0.05).

| Time on cART (years) | Crude log10 β (SE) | Adjusted log10 β (SE) | p-value |
|---|---|---|---|
| (3,6] | 0.030(0.007) | 0.012(0.0060) | 0.03 |
| (6,9] | 0.041(0.010) | 0.011(0.0086) | 0.18 |
| (9,12] | 0.030(0.008) | -0.0009 (0.007) | 0.88 |
| (12-15] | 0.051(0.008) | 0.0163 (0.007) | 0.02 |
| (15-18] | 0.11(0.027) | 0.063 (0.021) | 0.002 |

*[Crude and adjusted coefficients in the final linear model for the association between Arterial Stiffness and duration of cART]*

**Conclusions:** In HIV-infected participants cART did not increase AS when compared to those who were cART-naive, however long-term cART was independently associated with an increase in AS, particularly regimens containing PI.

## TUPEC150

### MARRIAGE OFFERS GREATER PROTECTION FROM HIV FOR MEN THEN IT DOES FOR WOMEN IN RURAL KWAZULU-NATAL

A. Radunsky[1], J. Bor[2], F. Tanser[3,4], T. Bärnighausen[1,3]
*[1]Harvard T.H. Chan School of Public Health, Global Health and Population, Boston, United States, [2]Boston University School of Public Health, Global Health, Boston, United States, [3]Africa Centre for Population Health, Mtubatuba, South Africa, [4]University of KwaZulu-Natal, Faculty of Health Science, Durban, South Africa*
*Presenting author email: apr814@mail.harvard.edu*

**Background:** Marriage may be protective against HIV acquisition, yet marriage in rural KwaZulu-Natal is often delayed due to the need to save for *lobola* (traditional bride price). A critical question is whether other long-term (often pre-marital) relationships may be equally protective. We assessed the association between marital status and HIV acquisition for men and women in an area of KwaZulu-Natal, South Africa, where non-marital long-term relationships are prevalent.
**Methods:** Using longitudinal data from the Africa Centre for Population Health (2001-2013) collected via demographic surveillance and repeat HIV biomarker collection, we assessed the relationship between relationship form (marital relationship and non-marital conjugal relationship) and HIV incidence, measured as a change in HIV serostatus across survey rounds. We assessed this association in interval censored Weibull proportional hazards models, controlling for age, education, having children, and having migrated.
**Results:** Men and women who were married had lower HIV incidence compared to those in unmarried conjugal relationships, controlling for other factors: adjusted hazard ratios were 0.536 (0.366-0.784) for men and 0.844 (0.738-0.964) for women. The protective association between marriage and HIV risk was significantly stronger for men than for women (p = 0.02). HIV risk was also positively associated with previously established predictors of HIV risk: migration, and additional concurrent conjugal relationships.
**Conclusions:** Marriage was associated with lower incidence of HIV acquisition in persons in long-term conjugal relationships. This association was significantly stronger for men as compared to women.

## TUPEC151

### NEED FOR ADEQUATE INVESTMENT AND REDESIGNING OF STRATEGIES FOR EFFECTIVE PREVENTION, TREATMENT, CARE AND SUPPORT SERVICES FOR HIV AND AIDS INTERVENTIONS IN A "MIXED" HIV EPIDEMIC NATION

E. Abatta[1], E. Ngige[2], C. Anyaike[2], S. Aboje[2], S. Araoye[2], A. Fagbamigbe[3], M. Mahy[4], M. Kugonza[5]
*[1]Federal Ministry of Health, Public Health, Abuja, Nigeria, [2]Federal Ministry of Health, Abuja, Nigeria, [3]University of Ibadan, Ibadan, Nigeria, [4]UNAIDS, Geneva, Switzerland, [5]Global Fund, Geneva, Switzerland*
*Presenting author email: emma_abatta@yahoo.com*

**Background:** Nigeria with population of 170 million has a generalized epidemic and HIV prevalence of 3.0%. Over 3.4 million persons are estimated to be living with HIV virus. Since 2001, the Prevalence has continued to decline from 5.8% in (2001), 4.6% (2008) to 3.0% in 2014. One major challenge that threatens to reverse the current achievement is the increasing prevalence of the key populations (KP) :- MSM, FSW and PWID etc, far above the national prevalence.
**Methods:** A meta-analysis of the results of the 2014 ANC and Syphilis sentinel survey conducted among 36,431 pregnant women aged 15 - 49 attending ANC for booking of index pregnancy in the 160 sentinel sites and the result of the 2014 Integrated Behavioural and Biological Surveillance Survey conducted among 22,841 High risk groups (MSM, Brothel Based Female Who Sell Sex (BBFWSS), Non Hotel Based Female Who Sell Sex (NBBFWSS), People who inject drugs (PWID), Transport workers, Police and the military). Respondent Driven Sampling was used for MSM & PWID while Time Location Sampling was used for the FWSS.
**Results:** The result showed that MSM had the highest prevalence of 22.9% (95% CI: 21.4-24.4) followed by BBFWSS 19.4% (95% CI: 18.1 - 20.6). The prevalence among the NBBFWSS is 8.6% (95% CI: 7.7 - 9.6) while the PWID is 3.4%.
The prevalence values among the KPs were higher compared with the results of the 2014 ANC sentinel survey and the 2012 population based survey which are 3.0% and 3.4% respectively.
While the BBFWSS, NBBFWSS and IDU has maintained a steady decline in prevalence as shown in the figure I, the MSM has consistently increased from 13.5% in 2007, 17.2% in 2010 to 22.9% in 2014.
**Conclusions:** Though, prevalence is declining, but with the current prevalence among the KP especially MSM, which is over 7 times higher than the general population prevalence, there is an urgent need for reprogramming and strengthening the current interventions in Nigeria. It is also important to factor the key populations in estimation and modeling. This is to ensure that the gains and successes so far in HIV control and prevention is not reversed.

## TUPEC152

### TARGETED AND EVIDENCE-BASED PRIORITIZATION IS NEEDED FOR CONTINUED HIV EFFORTS IN INDIA: HIV SENTINEL SURVEILLANCE (HSS) AMONG ANTENATAL CLINIC (ANC) ATTENDEES

N. Dhingra[1], P. Kumar[1], B. Sangal[1], Y. Raj[2], A.K. Singh[3], R. Sharma[4], D.S. Hausner[5]
*[1]Ministry of Health & Family Welfare, Government of India, National AIDS Control Organisation, New Delhi, India, [2]Independent Consultant, Hyderabad, India, [3]Oxford Policy Management, New Delhi, India, [4]John Snow India Private Ltd. (JSI), New Delhi, India, [5]JSI Research & Training Institute, Inc. (JSI), International Division, New Delhi, India*
*Presenting author email: dhausner@jsi.com*

**Background:** Surveillance is a vital component of any disease control program and has been implemented in India for HIV since 1985 and expanded in 2003 to include pregnant women attending ANC clinics throughout the country. This is a major undertaking in a country the size of India and information gained is necessary for strategic and evidence-based management of the National AIDS Control Programme.
**Methods:** Over a three month period, 294,732 pregnant women aged 15-49 attending ANC clinics - a proxy for the general population - during the current round of surveillance were consecutively sampled from 741 sentinel surveillance sites for the 2012-13 round of the HSS. Serum was collected anonymously through venous blood specimen and tested twice if the first test was HIV positive. Additionally, information on age, education, occupation, spouse's occupation, residence, and spouse's migration status was collected, and trends over time were analyzed using three-year moving averages.
**Results:** HIV prevalence among the ANC attendees of India was 0.35%. However, the spread of HIV in India is heterogeneous, with prevalence ranging from 0.00% in the states of Andaman & Nicobar Islands, Chandigarh, Dadra & Nagar Haveli, and Puducherry, to 0.88% in Nagaland, and even greater variation at district level, with 37 districts over 1.00%, and 12 sites as high as 2.00-3.00%. Across India, HIV prevalence was highest among women who were 15-24 years old, illiterate, rural residents, worked as hotel staff, and had spouses that were truckers or migrants. General

population HIV prevalence decreased overall in India from 2003-2013. However, in some regions, HIV prevalence remains high or is increasing.
**Conclusions:** India has made progress toward reducing HIV prevalence in formerly high prevalence states. Efforts and resources need to continue and intensify in emerging pockets of HIV and where HIV has consistently been high over the years. Targeted interventions should be focused on key affected sub-groups, such as young women, illiterate groups, hotel workers, truck drivers, and migrant workers. HIV testing and treatment needs to continue to expand to reach all people living with HIV.

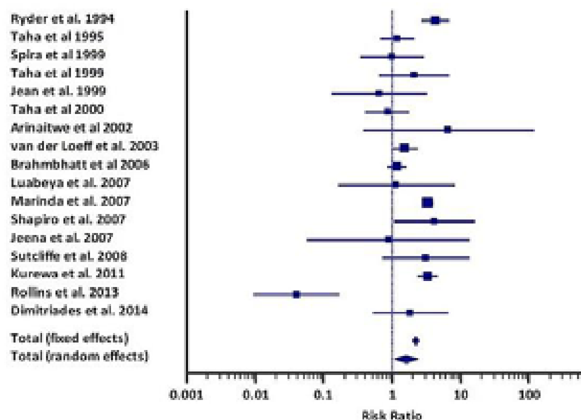
## EPIDEMIOLOGY OF HIV IN CHILDREN

### TUPEC153

#### MORTALITY IN HIV-EXPOSED UNINFECTED AND UNEXPOSED UNINFECTED INFANTS: A META-ANALYSIS

A. Brennan[1,2,3], R. Bonawitz[1], M. Buckley[1], C. Gill[1], D.M. Thea[1], H. Useem[3], L. Garrison[1], R. Ceccarelli[1], U. Chinenye[1], L. Long[2], M.P. Fox[1,2,3]
*[1]Boston University, Department of Global Health, Boston, United States, [2]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Johannesburg, South Africa, [3]Boston University, Department of Epidemiology, Boston, United States*
*Presenting author email: mfox@bu.edu*

**Background:** Successful implementation of programs to prevent mother-to-child-transmission of HIV (PMTCT) via maternal antiretroviral (ARV) provision has reduced the risk of perinatal transmission of HIV. Prior studies have demonstrated that HIV-exposed but uninfected (HEU) children experience infection and death at rates exceeding that for their HIV-unexposed and uninfected (HUU) counterparts. We conducted a meta-analysis to summarize the difference in mortality comparing HEU to HUU.
**Methods:** We searched studies published in English in PubMed, Web of Science, EMBASE, ProQuest and IAS and AIDS conference abstracts. Studies were included if they compared HEU to HUU infants and children and mortality, in any time period and in any setting. Due to heterogeneity between studies we used random effects models to calculate pooled risk ratios overall and then stratified by follow-up time (< 6 and ≥6 months) and year in relation to implementation of PMTCT in public sector (< 2002 vs. ≥2002). We also displayed results in a survival curve over 60 months of follow-up. For survival curves we interpolated mortality estimates for studies that had missing estimates at certain time periods.
**Results:** Of 199 studies receiving full text review,16 from sub-Saharan Africa and 1 from Haiti were included. HEU children had over a 60% increase in mortality compared to their HUU counterparts (RR:1.61; 95%CI: 1.08-2.39)(Figure).



*[Figure. Forest plot of risk ratios for morality comparing HIV exposed uninfected children to HIV unexposed uninfected children for all 17 studies]*

HEU vs. HUU children may be at greater risk of death in the first 6 months of life (RR:2.57; 95%CI: 0.69-9.62) than ≥6 months (RR:1.61; 95%CI: 1.06-2.44). Also, risk of mortality was also higher amongst HEU vs. HUU prior to the implementation of PMTCT (RR(<2002):1.78;95%CI: 1.20-2.64) compared to after (RR(≥2002):1.31;95%CI: 0.24-7.04).
**Conclusions:** For the first time, using meta-analytic techniques, we show an increased risk of mortality for HEU compared to HUU children. Further longitudinal research is needed with established cohorts to help elucidate underlying mechanisms for this difference in mortality between groups.

### TUPEC154

#### THE IMPACT OF HIV/AIDS ON THE CHILDREN'S RIGHT TO EDUCATION IN MYANMAR

M.-M. Mon[1], L.-L. Win[1], Y.-T. Nu-Oo[1], S. Saw[1], H.-N. Oo[2], P.-P. Win-Htin[3], K.-K. Zaw[1], S.-L. Tun-Myint[1]
*[1]Ministry of Health, Department of Medical Research, Yangon, Myanmar, [2]Ministry of Health, National AIDS Program, Nay Pyi Taw, Myanmar, [3]UNICEF, Yangon, Myanmar*
*Presenting author email: mmyomon@gmail.com*

**Background:** National data on situation of children from HIV affected families is needed for better planning of mitigation program for these affected children. Therefore, a nationwide survey was conducted in 30 townships from 13 States/Regions of Myanmar in 2013-2014.
**Methods:** It was a cross-sectional comparative study which aimed to identify and compare the education and basic material need conditions of children affected by HIV and AIDS (CABA) with children from neighborhood. CABA were children under 18 years whose parent(s) are living with HIV or lost one/both parents due to AIDS regardless of child's HIV status.
Age group matched children were recruited from neighborhood. Parents/guardians of 1,511 CABA and 1,511 controls were interviewed by using a pre-tested, structured questionnaire. In-depth interviews were conducted with providers and parents/guardians.
**Results:** Mean age of the children was 8.7±4.1 years and 46.8% of CABA were orphans. Over 24% of CABA were HIV infective and 75% have initiated ART. Among 5 to 17 years old children, 16.3% of CABA are not currently attending school which is significantly higher than their counterparts (9.1%) (P=0.001). Similarly, amongst 10 to 14 years old children, 14.7% of CABA compared to 5.7% of controls were out of school (P=0.001). School performance of 12.1% of CABA and 5.7% of controls were indicated by the guardians as below average (P=0.001). Considerably higher proportions of guardians of CABA expressed that they were unable to cover costs of school stationery (46.8% vs. 23.6%), school uniforms (42.1% vs. 18.5%), and other school expenses (43% vs. 22.3%) (P=0.0001). CABA school attendance ratio was 0.9 which shows relative disadvantage in school attendance between CABA and control children. During discussions, family economy, health condition of HIV infected children, stigma and discrimination at school were indicated as the reasons for discontinuing school.
**Conclusions:** The needs of out of school and HIV positive adolescents should be partially addressed through livelihood development initiatives and job placement. Stigma and discrimination at school environment and communities also need to be addressed. In conclusion, long term strategic plans should be drawn up for addressing the overall development of CABA especially focusing on their rights to education.

### TUPEC155

#### IMPACT OF HIV INFECTION AND ANTIRETROVIRAL THERAPY (ART) DURATION ON NEURODEVELOPMENT OUTCOMES AMONG CHILDREN AGED 7 TO 14 YEARS, IN RAKAI, UGANDA

H. Brahmbhatt[1], M. Boivin[2], V. Ssempijja[3], G. Kigozi[3], J. Kagaayi[3], D. Serwadda[4], A. Violari[5], R. Gray[6]
*[1]Johns Hopkins Bloomberg School of Public Health, Population, Family and Reproductive Health, Baltimore, United States, [2]Michigan State University, Lansing, United States, [3]Rakai Health Science Program, Entebbe, Uganda, [4]Makerere University, Kampala, Uganda, [5]Perinatal HIV Research Unit, Johannesburg, South Africa, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States*
*Presenting author email: hbrahmb1@jhu.edu*

**Background:** Despite the fact that over 90% of the over 3 million children estimated to be living with HIV/AIDS were in sub-Saharan Africa by the end of 2015, there is a paucity of data on the impact of HIV/AIDS on the neurodevelopment of children in resource-poor settings. The objective was to assess the impact of HIV infection and long term-ART on neurodevelopment outcomes among children aged 7 to 14 years. Our hypothesis was that long-term ART use would ameliorate neurodevelopmental sequelae of HIV infection.
**Methods:** HIV positive and negative mother-child pairs were recruited from the Rakai Community Cohort Study (RCCS) and ART clinics in Rakai and followed prospectively for over 4 years. The Kaufman Assessment Battery for Children (KABC II) was used to assess sequential and simultaneous processing, learning, planning, knowledge, and Fluid Crystalized Index (FCI) for overall functioning. Multivariable generalized linear models were used to estimate adjusted Prevalence Rate Ratios (adjPRR).
**Results:** Of the 370 mother-child pairs, 55% were HIV negative controls (MHIV-/CHIV-), 7% were HIV exposed but uninfected (MHIV+/CHIV-) and 37.9% were HIV positive mothers and children (MHIV+/CHIV+). Longer duration of ART (Table 1) was associated with a significant improvement of sequential processing skills, and each additional year of schooling was associated with a significant 30-40% decrease in

Tuesday 19 July Poster Exhibition

| Age standardized weight | 0.71 [0.5-0.94] | 1.23 [0.93-1.6] | 1.08 [0.7-1.71] | 1.16 [0.6-2.16] | 0.89 [0.7-1.1] | 1.45 [0.9-2.26] |

*[Table 1: Impact of ART treatment Duration on Neurocognitive Impairment among HIV Positive Children]*

**Conclusions:** Sequential processing skills pertaining to working memory were improved with prolonged ART duration and increased duration of schooling was associated with a reduction of neurodevelopment impairment. Early initiation and sustained use of ARTs as well as longer schooling are needed to reduce neurocognitive impairment among HIV infected school aged children.

## TUPEC156

### VIROLOGICAL RESPONSE TO FIRST-LINE ART IN CHILDREN IN THE EUROPEAN PREGNANCY AND PAEDIATRIC HIV COHORT COLLABORATION (EPPICC)

R.L. Goodall[1], E. Chiappini[2,3], D.M. Gibb[1], T. Klimkait[4], N. Ngo-Giang-Huong[5,6], C. Thorne[7], A. Turkova[1], A. Judd[1], European Pregnancy and Paediatric HIV Cohort Collaboration (EPPICC)
*[1]MRC CTU at UCL, Institute of Clinical Trials and Methodology, London, United Kingdom, [2]University of Florence, Florence, Italy, [3]Anna Meyer Children's University Hospital, Florence, Italy, [4]University of Basel, Basel, Switzerland, [5]UMI 174-PHPT, Chiang Mai, Thailand, [6]University of Chiang Mai, Chiang Mai, Thailand, [7]UCL Institute of Child Health, London, United Kingdom*
*Presenting author email: r.goodall@ucl.ac.uk*

**Background:** Studies comparing efficacy of PI- and NNRTI-based initial ART regimens in children have shown inconsistent results. We investigated virological response in children from 18 cohorts across 16 European countries and Thailand.
**Methods:** Time of virological suppression ('response') was estimated as the mid-point between the first VL<400c/mL and previous VL≥400c/mL. Multivariable stepwise logistic regression models (backwards elimination, exit probability p=0.05) were used to identify factors associated with virological suppression by 12 months from ART initiation (baseline).
**Results:** 2202 children initiating ART < 18 years with a boosted PI or NNRTI plus >2 NRTI had baseline VL and ≥1 VL measurement available within the first 15 months of ART. 91% were perinatally infected with median[IQR] age 3.8[0.8,8.5] years at HIV diagnosis and 6.4[1.6,10.7] years at ART initiation. Median[IQR] baseline CD4% was 16[8,24]. 91% achieved virological response by 12 months. In multivariable analysis, the effect of ART regimen on virological response varied by age at ART initiation (Table): in children <3 years, compared to a PI-based regimen, odds of response were significantly reduced for those starting a NVP+2NRTI regimen, but not significantly different for those initiating on NVP+3NRTI; conversely, children ≥3 years had higher odds of virological response compared to those <3 years, with no significant differences between regimens. Additionally, across all ages, starting an abacavir-containing regimen, VL <100,000 copies/mL, and more recent calendar year at ART initiation were associated with increased odds of virological response. Children in Russia/Ukraine had reduced odds of response. There was no significant effect of gender, being born abroad, baseline CDC clinical stage, CD4%, HCV/HBV-status or mode of infection.

| | | N (%) | aOR (95% CI) | p |

| | ≥100,000 c/mL | 1223 (56) | 0.70 (0.50, 0.97) | |
| Calendar year: | 1997-2003 | 610 (28) | 0.82 (0.57, 1.18) | 0.005 |
| | 2004-2007 | 808 (37) | 1.0 | |
| | 2008-2013 | 784 (36) | 1.71 (1.11, 2.62) | |
| Region: | UK/Ireland | 811 (37) | 1.33 (0.88, 2.01) | <0.001 |
| | Rest of Europe | 792 (36) | 1.0 | |
| | Thailand | 378 (36) | 0.82 (0.52, 1.29) | |
| | Russia/Ukraine | 221 (10) | 0.35 (0.21, 0.59) | |

*[Table: Factors at ART initiation associated with virological response by 12 months]*

**Conclusions:** Most children achieve virological suppression by 12 months. Response was more likely in recent years and less likely in children starting NVP+2NRTI <3 years, possibly due to under-dosing. Further work will explore predictors of virological failure.

## TUPEC157

### SPATIAL CONFOUNDING ADJUSTMENT OF CHILDHOOD MALNUTRITION IN RURAL NORTH-EAST SOUTH AFRICAN HOUSEHOLDS: A BAYESIAN MULTIVARIATE AND STRUCTURAL EQUATION MODELLING APPROACH

E. Musenge
*University of the Witwatersrand, Faculty of Health Sciences, Epidemiology and Biostatistics Division, School of Public Health, Johannesburg, South Africa*
*Presenting author email: eustasius.musenge@wits.ac.za*

**Background:** The extent of geographical-social disparities on childhood malnutrition associated with HIV, has hardly been explored yet it is a reservoir of information for effective public health interventions. Our primary aim was to determine factors associated with two malnutrition indicators (weight-for-age and height-for-age) adjusting for their multivariate spatial random effects. Secondarily, pathways linking independent factors, HIV and malnutrition indicators, were examined. We tested the hypothesis: "HIV retards child growth controlling for other factors and household spatial random effects".
**Methods:** We analyzed data from a cross-sectional anthropometric survey of 648 children aged 1 - 5 years collected in 2007. We employed a Bayesian multivariate spatial model to simultaneously analyze the two indicators of child malnutrition. To assess the mediator impact of HIV on correlated malnutrition indicators and other explanatory variables we used structural equation models adopting a systems thinking approach from spatially adjusted posterior estimates.
**Results:** Spatial multivariate adjusted analyses revealed a negative effect due to HIV and protective effects with older aged children and mothers, and maternal education. Pathway analyses of these factors showed that HIV had a significant mediator effect and the greatest worsening effect of -0.55 (95% CI: -1.09,-0.02) and -0.61(95% CI: -0.98,-0.24) for weight-for-age and height-for-age z-scores respectively.
**Conclusions:** Interventions directly or indirectly targeted at the mother are key in controlling malnutrition. Child malnutrition interventions can be more effective if there is a dual focus on those HIV infected and the geographical areas of greatest risk, which can be modeled as a system to guide policy makers more objectively. Public health population level interventions aimed at reducing malnutrition are pivotal in lowering morbidity and mortality in rural African areas.

## EPIDEMIOLOGY OF HIV IN YOUTH AND ADOLESCENTS

### TUPEC158

#### A CROSS-SECTIONAL STUDY OF HIV-RELATED KNOWLEDGE AND ATTITUDES AMONG MEDICAL AND PARAMEDICAL STUDENTS IN A UNIVERSITY, NEW DELHI, INDIA

F. Islam[1], S. Roy[2], R. Pathak[2], M. Parashar[2], R. Agarwala[2], M.C. Kapilashrami[1], A. Debroy[3]
*[1]HIMSR, Jamia Hamdard University, Community Medicine, New Delhi, India, [2]HIMSR, Jamia Hamdard, Community Medicine, New Delhi, India, [3]Public Health Foundation of India (PHFI), ITSU, New Delhi, India*
*Presenting author email: drfarzanaislam@gmail.com*

**Background:** The HIV/AIDS pandemic is in its fourth decade. However, stigma and discrimination at health care setting, work places and at educational institutions are still presents as challenges and concern. Hence, this study was conducted with an objective to determine the knowledge and attitude about HIV/AIDS and towards people living with HIV, among the first year medical and paramedical students.
**Methods:** This cross-sectional study was carried out at Jamia Hamdard University in October 2014. All the 100 medical and 100 paramedical students were considered for the study (absentees excluded). Hence a total of 179 students were interviewed. The data were collected using a pre-designed, pre-tested, alpha numeric coded, self-administered, structured questionnaire and further analysis was done using MS excel and other relevant statistical tests.
**Results:** Out of 200 students, 179 were present on the day of data collection. This study revealed that television (89.39%), the internet (87.15%), teachers (89.39%), newspapers (83.80%) and books (93.30%) were the students' major source of information on HIV/AIDS. Students (171) are more comfortable discussing HIV/AIDS with the friends of the same sex (95.5%). Regarding disease transmission, the majority of students (174) were aware of the major routes of transmission; however; 56 (31.2%) students believed that HIV can be transmitted through a mosquito bite. The study also revealed that 168 nos. of the students (93.8%) know that HIV is a preventable disease, and that condoms play an important role in prevention. Out of 179, only 89 nos. (49.7%) of students ever heard of anti-retroviral therapy. 167 (93.2%) students have respect towards people with HIV/AIDS, yet almost half of the students think that HIV+ couples should not have children.
**Conclusions:** This study indicates that students have a wide variety of sources to obtain information on HIV/AIDS. While students understand the major routes of transmissions, misconceptions persist. Further action is required to improve HIV--related knowledge and attitudes in this university setting.

### TUPEC159

#### COMMUNITY-BASED ADOLESCENT AND YOUTH HIV TESTING AND ENROLLMENT IN HIV CARE IN HAITI

L. Reif[1], V. Rivera[1], B. Louis[2], R. Bertrand[3], M. Peck[2], B. Anglade[3], E. Abrams[4], J.W. Pape[1,3], D. Fitzgerald[1], M. McNairy[1]
*[1]Weill Cornell Medical College, New York, United States, [2]GHESKIO Centers, Port-au-Prince, Haiti, [3]GHESKIO, Port-au-Prince, Haiti, [4]ICAP at Columbia University, New York, United States*
*Presenting author email: rachelbertrand@hotmail.com*

**Background:** Adolescents account for 40% of new HIV infections in Haiti, yet only 20% of adolescents know their HIV status. Community-based testing strategies may increase HIV testing among high-risk adolescents and youth.
**Methods:** A community-based adolescent and youth HIV testing and counseling (HCT) campaign was conducted in 7 slum areas of Port-au-Prince, Haiti from December 2014 to September 2015. Community health workers (CHW) provided community sensitization and recruited adolescents and youth ages 10-24 to test for HIV, Syphilis, Gonorrhea, Chlamydia, and pregnancy and screen for Tuberculosis (TB). Guardian consent was required for adolescents $\leq$16 years, per national guidelines. HIV-infected individuals were escorted to the GHESKIO HIV clinic for same-day enrollment in HIV care, which included confirmatory testing and point-of-care CD4 testing.
**Results:** Among 3,348 individuals tested, HIV prevalence was 2.65% (n=89), of whom 73% were female with median age of 19 years (IQR 17-20). HIV prevalence varied from 0.6% to 7.4% within slum areas (defined by participant address), and was 7.9% (14/177) among 10-15 year-olds compared to 2.4% (75/3,082) among 16-24 year-olds. 100% of HIV-infected individuals enrolled in care the same day as testing, with median CD4 529 cells/uL (IQR 363-761). Among all participants, 2.6% had syphilis infection and 9.3% had Gonorrhea or Chlamydia. 168 participants reported TB symptoms, and among those with symptoms, 13 (7%) had microbiologically-confirmed disease. Over 80% of 16-24 year-olds were sexually active, yet only 1% reported using modern family planning and 17% reported regular condom use. Challenges included the need for guardian consent for adolescents $\leq$16 years and violence in the slums which resulted in cancelled testing. There were no reported adverse events of social harms or loss of confidentiality.
**Conclusions:** This community-based HIV testing campaign identified an adolescent and youth population with an HIV prevalence three times higher than the estimated national adolescent HIV prevalence in Haiti (0.8%), including a subpopulation who likely acquired HIV perinatally. The campaign identified clustering of HIV across slum communities which may inform targeting of follow-up campaigns. Active recruitment of adolescents and youth for HIV testing is an approach which could control the HIV epidemic in Haiti.

### TUPEC160

#### CHANGING SOCIAL NETWORKS AND INCREASED HIV PREVALENCE IN KENYAN ADOLESCENT WOMEN

L. Balzer[1], W. Zheng[2], T. Ruel[2], E.D. Charlebois[2], T.D. Clark[2], E.A. Bukusi[3], C.R. Cohen[2], M.R. Kamya[4,5], D.V. Havlir[2], M.L. Petersen[6], G. Chamie[2], the SEARCH Collaboration
*[1]Harvard University, Boston, United States, [2]University of California, San Francisco, United States, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Makerere University College of Health Sciences, Kampala, Uganda, [5]Infectious Diseases Research Collaboration, Kampala, Uganda, [6]University of California, Berkeley, United States*
*Presenting author email: lbbalzer@hsph.harvard.edu*

**Background:** Kenyan adolescent women are at high risk of HIV infection: 2% prevalence in early adolescence (10-14 years), 3% in mid-adolescence (15-17) and 15% in late adolescence (18-24). Social relationships are also dynamic during this phase. Understanding the association between social networks and HIV infection may suggest novel intervention strategies. We sought to elucidate demographic and social predictors of HIV infection and to understand how social dynamics differed with age.
**Methods:** As part of the SEARCH trial (NCT01864603), 14,812 adolescent women were tested for HIV in rural Kenya. Along with demographic information, residents aged ≥15 were asked to name social contacts that provided support in five domains: health, money, emotions, food, and free time. For all adolescent groups, the adjusted relative risk (aRR) of each demographic predictor of HIV status was evaluated with targeted maximum likelihood estimation (TMLE), controlling for confounders. For the two older age groups, associations between network characteristics (number and age of contacts) and HIV status were evaluated with TMLE, adjusting for demographics.
**Results:** Risk factors for HIV infection varied by adolescent group. Among early adolescent women, significant predictors included maternal death (aRR:3.1) and living in a community with high adult HIV prevalence (aRR:1.6). Among mid-adolescent women, significant predictors included lower socio-economic status (aRR:2.5), self-reported sexual activity (aRR:2.4), and leaving school (aRR:2.0). Among late adolescent women, significant predictors included living in a high prevalence community (aRR:1.3) and leaving school (aRR:2.3). Social networks also differed by age. For all domains, late adolescent women named more contacts and older contacts than mid-adolescent women (p< 0.01). Having fewer adult (age>24years) social contacts with whom to discuss financial (aRR:4.3) and emotional matters (aRR:2.5) increased HIV risk among mid-adolescent women.
**Conclusions:** Demographic and social predictors of HIV infection, as well as egocentric social network characteristics, varied significantly by adolescent stage among Kenyan women. After controlling for known risk factors including poverty, leaving school, orphanhood, and sexual activity, low social support for financial and emotional concerns were associated with higher HIV risk in mid-adolescent women. Interventions to increase social support of adults to young women may reduce HIV incidence.

### TUPEC161

#### HIV TRENDS AMONG ADOLESCENTS AND YOUNG ADULTS, AGES 15-24, IN 23 HIGH-BURDEN COUNTRIES

C. Barker, S. Bowsky, A. Dutta
*Palladium, Washington DC, United States*
*Presenting author email: sara.bowsky@thepalladiumgroup.com*

**Background:** Coverage of HIV-related services among adolescents and young adults remains low, despite evidence of increased HIV risk among females in this age group in sub-Saharan Africa. In response, PEPFAR has launched the DREAMS initiative. Epidemiological data on these age groups are needed to inform implementation of DREAMS. However, there is a lack of such data in the current literature.
**Methods:** The USAID- and PEPFAR-funded Health Policy Project used official 2015 Spectrum files to analyze epidemiological trends among people, ages 15 to 24, in 23 high-burden countries. Analysis was based on seven indicators: prevalence, in-

### COCAINE USE INCREASES BIOMARKERS OF LIVER DISEASE IN THE MIAMI ADULT STUDIES OF HIV (MASH) COHORT

M. Baum[1], K. Sherman[2], S. Martinez[1], Y. Li[1], T. Stewart[1], C. Fleetwood[1], V. Ramamoorthy[1], I. Hatsu[3], O.D. Williams[1], J. Murillo[1], S. Lai[4], A. Campa[1]
*[1]Florida International University, Miami, United States, [2]University of Cincinnati, Cincinnati, United States, [3]Ohio State University, Columbus, United States, [4]Johns Hopkins University, Baltimore, United States*
*Presenting author email: baumm@fiu.edu*

**Background:** Advances in antiretroviral therapy (ART) have significantly reduced HIV-related mortality; however, substance abuse accelerates HIV-disease and may facilitate progression of liver disease. Hepatic injury results in fibrogenesis, associated with apoptosis, increased levels of plasma LPS and oxidative stress. While a proportion of people living with HIV (PLWH) engage in substance abuse, its effect on liver fibrogenesis is not known.
**Methods:** A total of 259 PLWH who were not co-infected with Hepatitis B or C were recruited from the MASH cohort and followed for biomarkers of liver disease for 24 months. Substance abuse was determined with questionnaires and confirmed with urine toxicology. AUDIT was used to determine alcohol consumption. Fasting blood was obtained for biomarkers of liver apoptosis (cytokeratin 18 [CK-18]), microbial translocation (LPS, sCD14), and oxidative stress (plasma glutathione and mitochondrial-specific 8-oxo-dG). Markers of HIV disease were obtained from medical records. Multivariable regression and Mixed Models were adjusted for age, gender, baseline CD4 counts, HIV-viral load and alcohol consumption.
**Results:** Mean age was 47.2±7.7SD years, 61% were men, and 77.5% Black. There were 77 PLWH who used cocaine during follow-up, and 182 PLWH who did not use cocaine. HIV-viral load was higher (*P*=0.019) and BMI was lower (*P*=0.026) among cocaine users. Cocaine users had higher levels of CK-18 (β=23.643, SE=11.53, *P*=0.041), plasma LPS (β=0.0399, SE=0.0186, *P*=0.0178), oxidized glutathione (β=0.051, SE=0.0267, *P*=0.049) and mitochondrial-specific 8-oxo-dG (β=0.052, SE=0.026, *P*=0.048), compared to cocaine non-users. CK-18 was higher with more frequent cocaine use (OR=5.45, 95%CI:1.07, 28.2, *P*=0.042) and was significantly related to FIB-4 (β=19.438, SE=4.1131, *P*< 0.0001) over a 24-months of follow-up.
**Conclusions:** Cocaine use was significantly associated with higher HIV viral load and lower BMI. Cocaine users had higher levels of liver apoptosis, plasma LPS, and oxidative stress compared to those who did not use cocaine. Moreover, more frequent use of cocaine was associated with higher level of liver apoptosis and with the progression of liver fibrosis over a 24-months of follow-up. Effective interventions to reduce cocaine consumption and target the biomarkers of liver fibrogenesis are needed to prevent complications of liver disease in PLWH.

## TUPEC173

### HIV RISK BEHAVIOURS AMONG FEMALE INJECTING DRUG USERS IN INDONESIA

C. Stoicescu, L. Cluver
*University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom*
*Presenting author email: claudia.stoicescu@spi.ox.ac.uk*

**Background:** Injecting drug users in Indonesia have an HIV prevalence rate of 36.4%. HIV transmission risk among female injecting drug users remains neglected in prevention research and in the national HIV response. The *Perempuan Bersuara* study examined HIV risk behaviors in the country's largest sample of active female drug injectors.
**Methods:** 731 female injecting drug users were recruited using respondent driven sampling from urban sites in Jakarta, West Java and Banten provinces between September 2014 and May 2015. Women were interviewed by trained peer fieldworkers using a structured questionnaire with standardized scales. The questionnaire included items on sexual and injection-related HIV risk and potential risk factors at the individual, interpersonal and structural levels. Descriptive statistical analyses were performed using STATA.
**Results:** Self-reported HIV prevalence was 47% (N=341). Women in the sample reported high injection-related risk as measured by injecting with someone else' used syringe and by sharing other injecting equipment such as filters, spoons/mixing containers and water used in drug preparation in the previous 30 days. Among sexually-experienced women (N=728), about 4 in 10 reported having multiple sexual partners (N=301; 41.4%). More than 1 in 3 women (N=250; 34.3%) reported engaging in transactional sex in the previous year. Rates of physical, injurious and sexual intimate partner violence were high at 51.9% (N=380), 35.9% (N=263) and 32.5% (N=237), respectively. Verbal, physical and sexual police harassment was reported by approximately 6 in 10 women who came into contact with law enforcement in the last year (63.8%, 210/329).
**Conclusions:** Female injecting drug users experience double HIV risk related to both sexual and injecting risk behaviours at multiple levels. HIV prevention programmes in the Indonesian context should acknowledge female injecting drug users as a distinct risk group requiring targeted intervention. High rates of intimate partner violence and police harassment in this sample warrant further attention in research and practice.

# EPIDEMIOLOGY OF HIV IN MALE, FEMALE AND TRANSGENDER SEX WORKERS

## TUPEC174

### PREVALENCE OF HIV AND ASSOCIATED RISKS OF COMMERCIAL SEX WORK AMONG YOUTH IN THE SLUMS OF KAMPALA

M. Swahn[1], R. Culbreth[1], L. Salazar[1], R. Kasirye[2], J. Seeley[3], J. Palmier[1]
*[1]Georgia State University, School of Public Health, Atlanta, United States, [2]Uganda Youth Development Link, Kampala, Uganda, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom*
*Presenting author email: mswahn@gsu.edu*

**Background:** Youth who engage in sex work are a key target population for HIV prevention because they are disproportionately burdened by HIV. The purpose of this analysis is to examine the prevalence of HIV among youth engaging in sex work in Kampala, Uganda, and to determine the psychosocial and environmental factors associated with increased risk.
**Methods:** Analyses are based on a cross-sectional survey data conducted in March 2014. Participants comprised a convenience sample (N=1,134) of urban service-seeking young people (aged 12-18 years, 56.1% female and 43.9% male) living on the streets or in the slums, who were participating in a Uganda Youth Development Link drop-in center. Bivariate and multivariate logistic regression analyses were conducted to examine factors associated with sex work (gender, age, education, parental drunkenness, parental living status, alcohol use, HIV/STD, previous rape, parental abuse of youth and experiencing suicidal ideations). IRB approvals were obtained from the Georgia State University and the Uganda National Council for Science and Technology.
**Results:** Among young people interviewed, 13.7% who have ever had sexual intercourse said they were engaged in sex work. The prevalence of self-reported HIV among these youth was 22.5%. The majority of youth started sex work between the ages of 15-16 (75.6%) and most were female (93.8%). Most of the youth were also paid by money for sex (97.5%), but a large portion of youth were paid in alcohol (40.7%). Engaging in sex work was associated with being female (AOR 9.0; 95% CI: 3.4, 24.0), being an orphan (AOR 3.3; 95% CI: 1.4, 7.5), ever drinking alcohol (AOR 6.8; 95% CI 2.9, 15.9), experiencing any rape (AOR 4.9; 95% CI: 2.7, 9.0), and having suicidal ideations in the previous year (AOR 1.8; 95% CI: 1.02, 3.4).
**Conclusions:** The prevalence of involvement in sex work is very high among youth in the slums of Kampala and is associated with a range of health risk and mental health concerns. In particular, the high level of HIV, alcohol use, and suicidality warrants immediate attention to reduce risk of further exacerbated health concerns, HIV transmissions, and mortality in this vulnerable population.

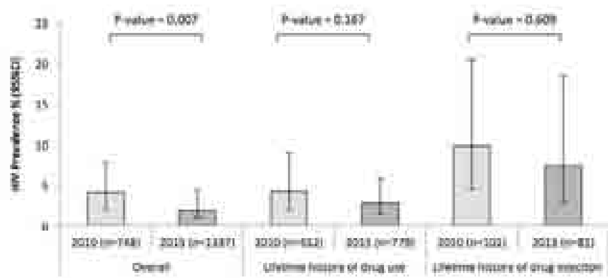
## TUPEC175

### HIV AND SEXUALLY TRANSMITTED INFECTIONS AMONG FEMALE SEX WORKERS IN IRAN: FINDINGS FROM THE 2010 AND 2015 NATIONAL SURVEILLANCE SURVEYS

A. Mirzazadeh[1,2], M. Shokoohi[2,3], R. Khajehkazemi[4], S. Hosseini Hooshyar[2], M. Karamouzian[2,5], S.A. Nadji[6], A. Shahesmaeili[2], H. Sharifi[2], A.A. Haghdoost[2]
*[1]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States, [2]Regional Knowledge Hub, and WHO Collaborating Centre for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [3]Schulich School of Medicine & Dentistry, University of Western Ontario, Department of Epidemiology & Biostatistics, London, Canada, [4]Research Center for Modeling in Health, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [5]School of Population and Public Health, Faculty of Medicine, University of British Columbia, Vancouver, Canada, [6]Virology Research Center, National Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of*
*Presenting author email: ali.mirzazadeh@gmail.com*

**Background:** Female sex workers (FSWs) acquire and transmit HIV and other sexually transmitted infections (STIs) through unsafe sex and injection with their partners. The 2010 and 2015 surveys assessed the prevalence of HIV and other STIs (only in 2015) in FSWs in Iran.

**Methods:** We conducted a facility-based plus street-based outreach sampling at 21 sites (25 in 2010) in 13 cities (12 in 2010) to recruit women aged ≥18 years reported selling sex to more than one male client in the past 12 months. Consenting FSWs were interviewed using a behavioral questionnaire and tested for HIV and five other STIs. We considered study sites as clusters in the analysis and 2-sided fisher's exact test to compare the HIV prevalence between the two rounds.
**Results:** In 2015, 1337 participants had a median age of 35 (IQR: 29-41) years. HIV prevalence was 1.9% (vs. 4.0% in 2010, p-value 0.007). Lifetime drug use and injection was reported by 59.8% (vs. 73.8% in 2010, p-value < 0.001) and 6.1% (vs. 13.6% in 2010, p-value < 0.001), respectively. In those with history of drug use, the HIV prevalence was 2.8% (vs. 4.2% in 2010, p-value 0.167) and in those who had ever injected drugs, it increased to 7.4% (vs. 9.8% in 2010, p-value 0.609) [Figure 1].



[Figure 1 - HIV prevalence overall and in subgroups of FSWs who reported lifetime history of drug use or injection in 2010 and 2015, Iran]

Prevalence of other STIs in 2015 was 0.4% (95%CI: 0.1, 1.4) for syphilis, 1.3% (95% CI: 0.7, 2.5) for Gonorrhea, 6.0% (95% CI: 3.9, 9.1) for Chlamydia, 11.9% (95% CI: 8.5, 16.5) for Trichomoniasis, and 41.8 (95% CI: 38.3, 45.5) for Human Papillomavirus.
**Conclusions:** HIV prevalence among FSWs in Iran is relatively low and stable if not decreasing, which may point to decrease in drug use or injection. Harm reduction programs for both sexual and injection harms need be continued and scaled up to further reduce the HIV transmission in FSWs.

## TUPEC176

### INCIDENCE AND TIME-VARYING PREDICTORS OF HIV AND SEXUALLY TRANSMITTED INFECTIONS (STIS) AMONG MALE SEX WORKERS IN MEXICO CITY

K.Y. Ganley[1], A.R. Zullo[2], S.G. Sosa-Rubi[3], C.J. Conde-Glez[3], M.N. Lurie[4], B.D.L. Marshall[4], D. Operario[5], K.H. Mayer[6], O. Galarraga[7]
*[1]Brown University School of Public Health, Providence, United States, [2]Brown University School of Public Health, Health Services, Policy & Practice, Providence, United States, [3]National Institute of Public Health (INSP), Cuernavaca, Mexico, [4]Brown University School of Public Health, Epidemiology, Providence, United States, [5]Brown University School of Public Health, Behavioral & Social Science, Providence, United States, [6]Fenway Health and Harvard University, Global Health, Boston, United States, [7]Brown University, Health Services, Policy & Practice, Providence, United States*
*Presenting author email: omar_galarraga@brown.edu*

**Background:** Male sex workers (MSWs) are a vulnerable population for acquisition of HIV/STIs. We estimated HIV/STI incidence rates and identified time-varying predictors of STI acquisition among MSWs in Mexico City.
**Methods:** MSWs recruited from ClínicaCondesa HIV Testing Clinic and community sites in Mexico City were tested and treated for STIs (chlamydia, gonorrhea, syphilis, and HIV) and viral hepatitis (hepatitis B and C) at a baseline, 6-month follow-up, and 12-month follow-up clinic visits. We estimated incidence rates and calculated 95% confidence limits using a bias corrected and accelerated bootstrap method with 1,000 replicates. We used mixed effects logistic regression with individual fixed effects to examine unadjusted and multivariable adjusted time-varying predictors of incident STIs.
**Results:** Among 227 eligible participants, the median age was 24 and baseline HIV prevalence was 32%. Incidence rates were as follows: HIV (5.28 per 100 person-years (PY); 95% 2.25, 11.75), chlamydia (4.63 per 100 PY; 95% 2.10, 9.09), gonorrhea (3.92 per 100 PY; 95%1.88, 7.58), active syphilis (12.44 per 100 PY; 95% 8.17, 18.51), hepatitis B (2.13 per 100 PY; 95% 0.52, 5.01), hepatitis C (0.96 per 100 PY; 95%0, 4.02), and any STI except HIV (21.00 per 100 PY; 95% 15.80, 30.69). In unadjusted mixed effects models, risk of incident STIs did not vary by older age, marriage, engagement in a stable romantic relationship, offering services to five or more clients, alcohol use, polysubstance use, sexual assault perpetration, condom use, provision of penetrative sex, or provision of receptive sex. However, risk of STIs did differ by educational attainment and was lower among those who completed high school (odds ratio (OR) = 0.28, 95% 0.09, 0.85) or college/post-grade education(OR=0.13, 95% 0.03, 0.53) compared to those who only had completed primary or secondary schooling. The association between risk of STI infection and completion of high school (adjusted OR [AOR]=0.23; 95% 0.06, 0.93) or college/post-graduate education (AOR=0.17; 95% 0.03, 0.93) persisted in the multivariable adjusted model.
**Conclusions:** HIV/STI incidence is high among MSW in Mexico City. Education appears to be an important potential predictor of HIV/STI infections, and may be an important component of economic and structural interventions to prevent infections.

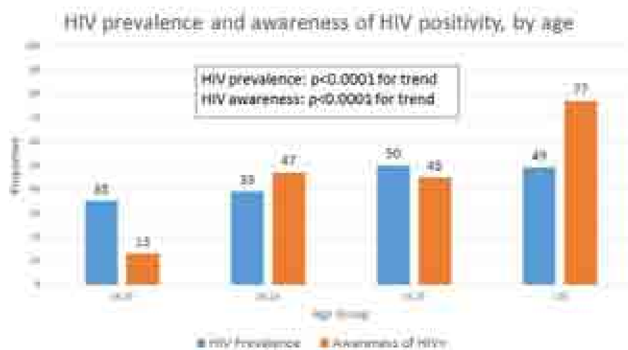
# EPIDEMIOLOGY OF HIV IN MSM

## TUPEC177

### HIGH PREVALENCE OF HIV AND LOW AWARENESS OF HIV INFECTION AMONG YOUNG MSM AND TRANSGENDER WOMEN IN CAPE TOWN AND PORT ELIZABETH, SOUTH AFRICA

P. Sullivan[1], S. Baral[2], N. Phaswana-Mafuya[3], T. Sanchez[1], R. Zahn[1], R. Kearns[1], K. Dominguez[4], C. Yah[2,3], L.-G. Bekker[4]
*[1]Emory University Rollins School of Public Health, Epidemiology, Atlanta, United States, [2]Johns Hopkins University Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Human Sciences Research Council, Port Elizabeth, South Africa, [4]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa*
*Presenting author email: pssulli@emory.edu*

**Background:** Men who have sex with men (MSM) and transgender women (transwomen) are disproportionately impacted by HIV globally, but data about the burden of HIV across Sub-Saharan Africa remain sparse. Understanding the patterns of the burden and awareness of HIV infection is important in defining the scale and content of HIV prevention, treatment, and care programs.
**Methods:** The Sibanye Health Project is a longitudinal cohort study of MSM/transwomen in Cape Town (CT) and Port Elizabeth (PE), South Africa, recruited by outreach in community settings. At baseline, participants were tested for HIV using the provincially approved algorithm. Demographic, behavioral, and clinical data were collected by study staff and through tablet-administered surveys. Age- and race- specific prevalence are described; differences by race were evaluated with chi-squared tests, and trends by age were evaluated with the Cochran-Armitage test for trend.
**Results:** 292 participants enrolled, 115 in CT and 177 in PE (88% black, 12% coloured or white; 15% aged 18-19, 42% 20-24, 20% 25-29, 24% ≥30; 91% MSM, 9% TW). HIV prevalence was 46% (CT:30%; PE: 51%). HIV prevalence increased with age (Figure) and was higher among black (46%) than coloured/white (21%; p< 0.0001). 42% of those living with HIV were aware of their HIV infection; awareness increased with age (Figure) but was not different by race.



[HIV Prevalence and Awareness of HIV Positivity, by Age]

**Conclusions:** HIV prevalence was high in both cities. Prevalence of 35% among 18-19 year olds suggests early sexual initiation and/or very high HIV incidence among young MSM/transwomen. HIV prevention programs for MSM and transwomen should include PrEP and should address the needs of adolescent and young populations. HIV testing programs should also target adolescent and young MSM/transwomen, among whom 8 of 9 living with HIV were unaware of their infection.

### HIV PREVALENCE AND UNPROTECTED ANAL INTERCOURSE AMONG MSM IN JAPAN: A SYSTEMATIC REVIEW

M. Omoto[1], L.-V. Le[2], M. Ohisa[1], T. Akita[1], B.A. Muzembo[1], J. Tanaka[1]
*[1]Hiroshima University, Department of Epidemiology, Infectious Disease Control and Prevention, Institute of Biomedical and Health Sciences, Hiroshima, Japan, [2]World Health Organization Regional Office for the Western Pacific, Manila, Philippines*
*Presenting author email: b126022@hiroshima-u.ac.jp*

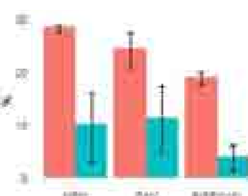
**Background:** In Japan, HIV infection is prevalent in men who have sex with men (MSM), who constitute the greatest number of the cumulative 24,000 reported HIV cases and accounted for 72% of cases in 2014. Despite high infection numbers, understanding of the burden of HIV among MSM in Japan remains limited. We aimed to assess the HIV burden and risk behaviors, specifically unprotected anal intercourse (UAI), among MSM in Japan in order to inform HIV programs.
**Methods:** We searched PubMed, Embase, Ichushi-Web (a database of Japanese biomedical literature), and the Ministry of Health, Labour and Welfare Grants System database (MHLW), which contain technical reports, published up to December 15, 2015. Studies of any design that measured the prevalence of HIV and UAI and associated factors among MSM across Japan, published in English or Japanese, were included. We used Comprehensive Meta-Analysis Version 3 to obtain HIV prevalence and 95% confidence intervals (CI).
**Results:** Of 127 selected publications, 33 were related to HIV infection and 94 to UAI. Ninety percent of studies were from MHLW, and almost all studies applied convenient sampling methods. The pooled HIV prevalence was 2.9% (CI: 2.5-3.3) across Japan. City-level HIV prevalence was highest in Tokyo (6.7%; CI: 4.6-8.9), followed by Osaka (3.5%; CI: 2.9-4.1), Yokohama (2.9%; CI: 1.4-4.3), Nagoya (2.2%; CI: 1.7-2.6), and Okinawa (1.8%; CI: 0.1-3.7). Simulation studies estimated HIV prevalence reaching 10% by 2040. We were unable to locate studies on HIV-associated risk factors. UAI prevalence in the past 6 months was high, ranging from 41.2-84.5%. UAI prevalence was higher among men having sex with regular male partners than with casual partners. Four studies reported on risk factors of UAI, which is strongly associated with self-perception of not being at risk, increased number of partners, and drug use.
**Conclusions:** HIV and UAI among MSM is an emerging public health concern in Japan. The problem is likely to increase in the future if no action is taken. Practical interventions and rigorous studies (population-based) to inform interventions are needed.

## TUPEC179

### EPIDEMIOLOGICAL SYNERGY: THE ROLE OF HETEROSEXUAL HIV TRANSMISSION IN THE SPREAD OF HIV AMONG MEN WHO HAVE SEX WITH MEN IN SOUTH AFRICA

P. Mulongeni, L. Johnson
*University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa*
*Presenting author email: leigh.johnson@uct.ac.za*

**Background:** South African men who have sex with men (MSM) have among the highest HIV prevalence levels in MSM populations globally, but the reasons for this are not well understood. Previous mathematical models have not accounted for interactions between MSM and heterosexuals in generalized HIV epidemics.
**Methods:** An agent-based model of the heterosexual HIV epidemic in South Africa was extended to include MSM, with distinction between 'gay' men (always homosexual) and 'bisexual' men (propensity for same-sex activity changing over the life course). The model was calibrated to HIV prevalence and sexual behaviour data from South African studies of MSM, as well as data on HIV prevalence in the general population.
**Results:** Consistent with MSM surveys, the model estimates that a high proportion of South African MSM are bisexual, and MSM sexual activity is concentrated at young ages. Median HIV prevalence in MSM in 2010 is estimated at 28.2% (IQR: 27.4-28.9%), compared to 14.2% (IQR: 13.6-14.6%) in all men aged 15-49. When the model was used to simulate a counterfactual scenario in which heterosexual transmission was set to zero (mimicking a concentrated epidemic setting), median HIV prevalence in MSM declined to 10.7%, with the proportional reduction in prevalence being substantially greater in bisexual men than in gay men (Figure).



*[Figure: HIV prevalence in 2010]*

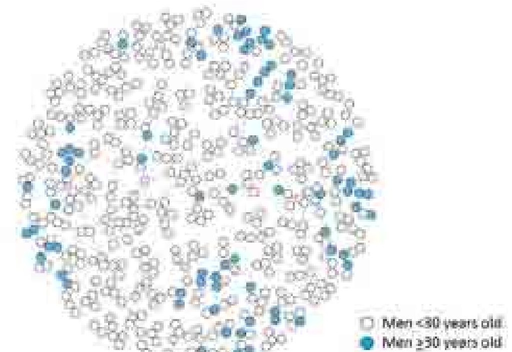
Male-to-male transmission in the counterfactual scenario was 50% lower than that in the main scenario.
**Conclusions:** The extremely high levels of HIV prevalence in South African MSM are to some extent due to the high level of HIV prevalence in the general population, and are not only the result of risk behaviours specific to MSM. Interventions to reduce male-to-male transmission among MSM should not ignore the substantial acquisition of HIV from female partners.

## TUPEC180

### SOCIAL NETWORK CHARACTERISTICS AND HIV INFECTION AMONG OLDER BLACK SOUTH AFRICAN MSM

J. Knox[1], T. Sandfort[2], T. Lane[3], V. Reddy[4]
*[1]Columbia University, Epidemiology, New York, United States, [2]Columbia University, Psychiatry/Gender, Sexuality and Health, New Yorl, United States, [3]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [4]University of Pretoria, Faculty of Humanities, Pretoria, South Africa*
*Presenting author email: justinryanknox@gmail.com*

**Background:** Studies conducted among populations of MSM in sub-Saharan Africa primarily reach young MSM; older MSM who have participated were found to have an increased risk of HIV infection. The current study aims to explore the social network characteristics, HIV status, and potential causal pathways for HIV infection among older black South African MSM.
**Methods:** An HIV prevalence study with behavioral survey was conducted using respondent driven sampling among 480 black MSM in Tswhane, South Africa. Social network characteristics were calculated using recruitment ties among participants. Multivariate analyses were conducted using ordinary least squares regression models.
**Results:** The overall mean age was 24 years. Eighteen percent (18%) were thirty years or older.



*[Figure 1. Distribution of men ≥30 years old among networks of n=480 black MSM in Pretoria, South Africa]*

Older men (≥30) did not differ from younger men in social network size (p=.99) or the number of men they recruited into the study (p=.42). Older men were more likely to refer another older man (60% vs. 16%, p< .001) and be referred by another older man (49% vs. 15%, p< .001). Thirty percent (30%) of men were HIV positive. Older men were more likely to be HIV infected (48% vs. 27%, p< .001). Older age was a risk factor for HIV infection (aOR=2.5, 95%CI: 1.6-4.1, p< .001). While older men reported more UAI over the past 6 months (mean=20 vs. 10, p=.02), this nor any other characteristic mediated their risk for HIV infection.
**Conclusions:** Older MSM were under-represented in this study and were found to bear a disproportionate burden of HIV infection. While older men reported more frequent UAI, this nor other HIV risk factors explained their increased burden of HIV infection. Our findings suggest the need to find effective ways to include older MSM in research in order to achieve more representative samples. This might also benefit prevention efforts as these are likely to be confronted with the same problem.

## TUPEC181

### PANEL CONDITIONING AS A THREAT TO VALIDITY IN SEXUAL BEHAVIORAL TRIALS OF GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN: RESULTS OF THE MEN'S INTERNET III (MINTS-III) TRIAL

B.R.S. Rosser
*University of Minnesota, Division of Epidemiology and Community Health, Minneapolis, United States*
*Presenting author email: aslele@umn.edu*

**Background:** In repeated measurement trials (e.g., RCTs), the effect of earlier surveys on later results is termed 'panel conditioning', 'time in sample bias,' or 'reactivity'. Least committed and Black respondents appear to be more susceptible to behavioral change through being surveyed. Panel conditioning effects, studied across a wide range of behaviors, appear to reflect *genuine* behavior change. The *Cognitive Stimulus (CS)* model posits that being asked questions (even in surveys) stimulates reflection on behavior, which increases motivation, and behavior change. This potentially explains why answering questions on a survey can substantially reduce risk behavior.
**Methods:** To study the frequency of panel conditioning on HIV prevention trials of gay bisexual and other men who have sex with men (GBM), we reviewed ten recent RCTs of sexual risk behavior in GBM. To test panel conditioning effects directly, the MINTS-III trial was an online RCT (N=1,450 GBM) with three recruitment periods: 6 months before the study (wash-in group), at baseline (traditional group) and a no-baseline immediate post-test group. All participants completed sexual risk assessments every three months until 12 months post-intervention.
**Results:** Operationalizing evidence of panel conditioning as reduced risk behavior in the control arm ($T_2$-$T_1$), ten of ten published studies (100%) showed evidence of panel conditioning effects. In our RCT, across both treatment and control, and at each wave, all groups showed evidence of panel conditioning effects sustained over twelve months. Effect sizes of 5-20% at each time period remained evident both when analyzing frequency totals for the whole sample, and in sub-analyses controlling for attrition.
**Conclusions:** Panel conditioning is extremely common in HIV prevention trials of GBM producing significant effects sizes. In behavioral trials, the effect sizes observed in MINTS-III appear sufficient to mask intervention effects. In biomedical trials, including those for PrEP, panel conditioning may lead to behavioral compensation being under-reported or missed. Researchers should consider adding wash-in periods (covering up to 3 behavioral assessments) when designing behaviorally focused RCTs. Intervention designers should incorporate monitoring risk behavior at regular intervals as it appears a strong intervention component to lower risk behavior.

## TUPEC182

### LABORATORY-CONFIRMED DIAGNOSES OF AND SELF-REPORTED TESTING BEHAVIORS FOR HIV AND STIS AMONG MSM IN TAJIKISTAN

K. Gulov[1,2,3], R.W.S. Coulter[2], D.D. Matthews[2], R. Stall[2], M. Uzzi[2], TR_Team
*[1]Equal Opportunities, Dushanbe, Tajikistan, [2]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, United States, [3]amfAR, New York, United States*
*Presenting author email: kgulov.eotj@gmail.com*

**Background:** Little is known about the prevalence and associations of HIV/STI diagnoses and testing behaviors among men who have sex with men (MSM) in Tajikistan.
**Methods:** A non-governmental organization conducted a cross-sectional study (n=502) of MSM assessing laboratory-confirmed HIV/STI diagnoses, self-reported HIV/STI testing prevalence in the past six months, sociodemographics, HIV/STI risk factors, and victimization/discrimination. Data for this study were collected from March through August 2015. Participants first completed a questionnaire on various topics (e.g., demographics, sexual risk behaviors, and HIV and STI testing behaviors) administered by trained Equal Opportunities staff. Participants on average took 20 to 45 minutes to complete the questionnaire. After completing the interviewer-administered survey, Equal Opportunities staff provided voluntary counseling for HIV/STIs. Participants were then offered to have blood drawn to get tested for HIV and other STIs. A trained nurse from the Tajikistan AIDS Centers administered all blood draws. All men that participated in any part of this study were incentivized with a hygiene package, which included a number of toiletries. All study procedures were approved by both the Bioethics Committee of the Academy of Medical Sciences through the Ministry of Health and Social Welfare of the Republic of Tajikistan and the University of Pittsburgh's Institutional Review Board.
**Results:** In total, 2.6% were diagnosed with HIV, 2.2% with syphilis, 17.6% with chlamydia, and 56.0% with herpes. Prevalence rates for recent HIV and STI testing were low (35.9% and 14.1%, respectively). In multivariable models, MSM with a high school education or less had lower odds of recent HIV and STI testing compared to men that completed university (odds ratio [OR]=0.43 and 0.23, respectively).
**Conclusions:** Given the low HIV prevalence, there is a window of opportunity to extinguish the epidemic before it worsens. Non-governmental organizations are indispensable for expanding testing strategies because they can efficiently reach MSM in Tajikistan.

## TUPEC183

### RISK FACTORS FOR ACUTE HIV INFECTION AMONG THAI YOUNG MEN WHO HAVE SEX WITH MEN

W. Thienkrua[1], W. Leelawiwat[1], P.A. Mock[1], W. Sukwicha[1], E.F. Dunne[1,2], B. Raengsakulrach[1], P. Wasinrapee[1], A. Chitwarakorn[3], P. Sirivongrangson[3], T.H. Holtz[1,2]
*[1]Thailand MOPH - U.S. CDC Collaboration, Nonthaburi, Thailand, [2]Division of HIV/AIDS Prevention, U.S. Centers for Disease Control and Prevention, Atlanta, United States, [3]Thailand Ministry of Public Health, Department of Disease Control, Nonthaburi, Thailand*
*Presenting author email: hpx8@cdc.gov*

**Background:** Men who have sex with men (MSM) and transgender women (TGW) are disproportionately affected by HIV in Bangkok, Thailand, and high incidence has been documented among younger members of these two populations in Asia. We evaluate factors associated with acute HIV infection (AHI) among young MSM and TGW in the Bangkok MSM Cohort Study (BMCS).
**Methods:** From 2006 to 2010, we enrolled Thai MSM and TGW aged ≥18 years into the BMCS, and followed participants for 3-5 years; for this analysis we restricted our data to those 18-24 years old. Socio-demographic and behavioral information were collected at each 4-month visit. At baseline and at each follow-up visit, anti-HIV Ab testing was performed on oral fluid with serologic confirmation. Starting in February 2010, blood samples from participants with oral fluid non-reactive anti-HIV were screened for AHI using pooled nucleic acid amplification testing (Aptima) and confirmed by viral load (Roche) and/or fourth generation EIA (Abbott). AHI was defined as undetectable anti-HIV Ab in blood with the presence of HIV-1 RNA and/or p24 Ag. We determined the proportion of participants with AHI and assessed factors independently associated with AHI using generalized estimating equations logistic regression modeling.
**Results:** From February 2010 to November 2015, we evaluated AHI in 343 young MSM and TGW with undetectable anti-HIV Ab in 2,253 visits. Median age among this subset was 22 years old. We detected AHI in 17 (5.0%) young MSM and TGW (0.8 infections per 100 tests, 95% CI 0.4-1.2). Factors independently associated with AHI included reporting more than two male steady partners in the past 4 months (adjusted Odds Ratio (aOR) 4.7, 95% CI 1.1-20.9), reporting fever in the past 4 months (aOR 5.9, 95% CI 1.1-32.2), positive hepatitis B core antibody (aOR 15.8, 95% CI 2.8-88.5), and ever having rectal *Neisseria gonorrhea* (aOR 58.2, 95% CI 5.2-645.3).
**Conclusions:** Among young Thai MSM and TGW in our cohort who tested negative for anti-HIV, 5% had AHI. A history of STIs were highly associated with AHI. Increasing HIV and STI screening among young MSM and TGW can support and enhance HIV prevention efforts through provision of early treatment.

## TUPEC184

### INTIMATE PARTNER VIOLENCE AND HIV INFECTION AMONG MEN WHO HAVE SEX WITH MEN IN SHANGHAI, CHINA

Y. Liu[1], C.X. Liu[2], Z. Ning[3], H. Zheng[4], Y.Y. Zhang[5], M.Y. Gao[2], Y.Y. Ding[2], N. He[2]
*[1]School of PublicHealth, Fudan University; and Putuo District Center for Disease Control and Prevention, Department of Epidemiology, Shanghai, China, [2]School of Public Health, Fudan University, Shanghai, China, [3]Shanghai Municipal Center for Disease Control and Prevention, Shanghai, China, [4]Shanghai Piaoxue Cultural Media Limited, Shanghai, China, [5]Putuo District Center for Disease Control and Prevention, Shanghai, China*

**Background:** Intimate partner violence (IPV) research is extremely limited among Chinese men who have sex men (MSM), a population playing key roles in HIV epidemic. We examined prevalence and correlates of IPV and HIV infection among MSM in Shanghai, China.
**Methods:** All MSM attending two voluntary HIV counseling and testing clinics in Shanghai during Mar.2015 to Aug. 2015 were recruited to participate in a cross-sectional survey. To measure male-on-male IPV, participants were asked about lifetime experience of violence perpetration against or from intimate male partners. Violent behaviors included being hit or thrown objects, being threatened with harm or harm to others, being threatened to reveal sexual orientation, being physically forced to have sex, or destruction of property. Separate multiple logistic regression analyses were conducted to determine correlates of IPV and their association with HIV infection.

### FLUCTUATIONS IN DEPRESSION AND HIGH-RISK SEXUAL BEHAVIOR AMONG YOUNG BLACK GAY AND BISEXUAL MEN IN NEW YORK CITY

P. Wilson[1], G. Stadler[2]
*[1]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States, [2]University of Aberdeen, Aberdeen, United Kingdom*
*Presenting author email: pw2219@columbia.edu*

**Background:** Young black gay and bisexual men (YBGM) are one of the only groups with increasing HIV incidence in the United States. This population also has limited access to prevention and treatment strategies. While many studies have shown weak evidence for a relationship between depression and risk behavior, these studies are plagued by methodological problems; findings should be considered inconclusive. YBGM contend with a variety of social and environmental factors that influence mental health, and strengthen a relationship between depression and risk behavior. This study examines associations between within- and between-person changes in depression, and high-risk sexual behavior, among YBGM in New York City.
**Methods:** Data were obtained from 124 YBGM (mean age = 25 years). Participants completed weekly surveys for 2 months. Self-report measures assessed details of sexual encounters had over the 8-week study time period, including condom use and partner HIV status. Participants also completed brief weekly depression assessments using the K-10 (Kessler et al., 2002) and POMS depression subscale (McNair et al., 1981). Multi-level logistic models were used to examine within- and between-person associations of depression and HIV risk behavior.
**Results:** Over the 8-week time period, participants reported on 460 sexual episodes (mean = 3.7). Twenty-eight percent of participants reporting having sexual episodes involving serodiscordant condomless anal intercourse (CAI), and 15% reported engaging in high-transmission risk CAI (e.g, HIV- men engaging in receptive CAI with HIV+ partners). Within-person changes in depression were shown to be associated with serodiscordant CAI and high-transmission risk CAI - when participants were more depressed than average (i.e., their person-mean), they were more likely to report have a risk episode (*ps* = .01 - .03). Additionally, using the K-10, we observed between-person differences were positively related to risk episodes (*p* = .01).
**Conclusions:** This study is one the first to examine the association of within-person changes in depression with HIV risk behavior in YBGM. It contributes new evidence to literature exploring the relationship between depression and sexual risk, and provides direction for intervention. Future research should employ longitudinal designs to explore pathways linking within-person changes in depression with risk behavior.

## EPIDEMIOLOGY OF HIV IN SERODISCORDANT COUPLES

## TUPEC191

### FACTORS ASSOCIATED WITH FERTILITY DESIRES AND PREGNANCY INCIDENCE AMONG HIV-POSITIVE CONCORDANT AND SERODISCORDANT COUPLES IN RAKAI, UGANDA

H. Brahmbhatt[1], F. Makumbi[2], T. Lutalo[3], J. Santelli[4], D. Serwadda[2], R. Gray[5], Rakai Health Science Project
*[1]Johns Hopkins Bloomberg School of Public Health, Population, Family and Reproductive Health, Baltimore, United States, [2]Makerere University, Kampala, Uganda, [3]Rakai Health Science Program, Entebbe, Uganda, [4]Columbia University Mailman School of Public Health, New York, United States, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States*
*Presenting author email: hbrahmb1@jhu.edu*

**Background:** In communities characterized by high levels of fertility and HIV infection, it is important to assess factors affecting HIV risk and pregnancy rates. Couples were followed prospectively from 2001 to 2011 and factors potentially influencing pregnancy desire and pregnancy rates were examined.
**Methods:** We linked longitudinal data from 10 years from the Rakai Community Cohort Study in Rakai, Uganda from HIV negative (M-F-), concordantly HIV-infected (M+F+), and discordant (M+F- or M-F+) couples. We used multinomial regression models to estimate the prevalence rate ratios (PRR) of desiring more children, and pregnancy incidence by couples HIV serostatus.
**Results:** A total of 2606 couples contributed to 16,399 couple-rounds of observations. Fertility desire decreased with increasing female age and schooling, irrespective of HIV status. Other factors associated with fertility desire (Table 1) were report of non-marital relationships by the male or female partner, the number of co-resident biological children, and whether one or both of the HIV-positive spouses were enrolled in HIV care. Pregnancy incidence was lower among older women and when both partners were HIV positive; pregnancy incidence was higher among women of low and medium SES compared with high SES; women with more than one co-resident child; and women who desired more children. When stratified by couples' HIV status, pregnancy incidence was higher among HIV serodiscordant couples compared with seropositive concordant (adjPRR: M-F+1.74(1.01-3.0), M+F-1.73(1.04-2.89).

| | M-F adjPRR (95%CI) | M+F+ adjPRR (95% CI) | M-F+ adjPRR (95%CI) | M+F adjPRR (95%CI) |
|---|---|---|---|---|
| Non-Marital Relationships (Ref=None) | 1.00 | 1.00 | 1.00 | 1.00 |
| Female | 0.9(0.84-1.1) | 1.5(1.13-2.12) | 1.9(1.11-3.26) | 0.9(0.62-1.4) |
| Male | 1.1(1.04-1.12) | 1.2(1.01-1.42) | 1.0(0.8-1.3) | 1.0(0.8-1.32) |
| Co-resident biological children (Ref=0) | 1.00 | 1.00 | 1.00 | 1.00 |
| 1-2 | 1.1(1.03-1.12) | 0.9(0.7-1.02) | 0.9(0.71-1.15) | 0.7(0.6-0.9) |
| 3-5 | 0.7(0.71-0.78) | 0.5(0.42-0.67) | 0.6(0.43-0.82) | 0.5(0.35-0.6) |
| 6+ | 0.3(0.24-0.32) | 0.1(0.02-0.34) | 0.4(0.14-1.1) | 0.3(0.15-0.61) |
| HIV+ spouse in care | | 0.8(0.64-1.05) | 0.5(0.37-0.73) | 0.9(0.68-1.11) |
| Both HIV+ partners in care | | 0.6(0.45-0.77) | | |

*[Table 1: Prevalence Rate Ratios of Desiring More Children by HIV status of Couples]*

**Conclusions:** Couple's HIV serostatus and enrolment in HIV care significantly impact both the desires for more children and pregnancy incidence. Although couples with co-resident children desired less children, pregnancy rates among these couples were significantly higher indicating a need to address the potential unmet need for contraception among these couples. Where HIV prevalence and fertility are high, understanding risk factors is critical in order to ensure effective pregancy prevention and safe pregnancy outcomes among HIV infected couples.

## TUPEC192

### RISKY SEX AND HIV ACQUISITION AMONG HIV SERODISCORDANT COUPLES IN ZAMBIA: WHAT DOES ALCOHOL HAVE TO DO WITH IT?

D. Joseph Davey[1], K. Wall[2], M. Inambao[3], W. Kilembe[3], N. Htee Khu[2], I. Brill[4], B. Vwalika[3], E. Chomba[3], J. Mulenga[3], A. Tichacek[2], S. Allen[2], Rwanda-Zambia HIV Research Group
*[1]University of Californa, Los Angeles, Epidemiology, Los Angeles, United States, [2]Emory University, Atlanta, United States, [3]Rwanda-Zambia HIV Research Group, Lusaka, Zambia, [4]University of Alabama, Birmingham, United States*
*Presenting author email: dvoradavey@gmail.com*

**Background:** Heavy alcohol use is a widespread problem among those at risk for and living with HIV, and its use by at least one partner can affect HIV transmission and acquisition risks to both partners. This study evaluates the effects of alcohol consumption on high-risk sexual behavior and HIV acquisition in a prospective longitudinal cohort of 3,049 serodiscordant couples in Lusaka, Zambia.
**Methods:** We evaluated factors associated with alcohol consumption at baseline, and its effect on having outside sexual partnerships and condomless sex with primary partner using multivariable logistic regression. We analyzed the effect of alcohol consumption on HIV acquisition using mutivariable Cox models stratified by gender of HIV-infected partner.
**Results:** Over one-half of couples were female HIV-positive (n=1656; 54.3%). Only 3.2% women reported getting drunk weekly or daily/almost daily, compared to 33.5% men. Factors associated with women's alcohol use included older age (aOR=1.03; 95%CI=1.01, 1.05), partner heavy drinking (aOR=4.13; 95%CI=3.29-5.19), and HIV-positive status at baseline (aOR=1.62; 95%CI=1.27-2.05). Among men, heavy drinking was associated with younger age (aOR=0.98; 95%CI=0.96-0.99), age disparity with partner (aOR=1.04; 95%CI=1.02-1.06), STI in last year (aOR=1.21; 95%CI=1.06-1.38), and partner heavy drinking (aOR=2.83; 95%CI=2.00-4.04). Men's heavy drinking was associated with increased odds of having outside partnerships (aOR=2.02; 95%CI=1.58-2.57) and condomless sex with main partner in past 3-months (aOR=1.61; 95%CI=1.28-2.04) compared to non-drinkers. Women's heavy drinking was associated with an increased odds of having outside partners (aOR=1.89; 95%CI=1.35-2.64), and condomless sex with main partner in the past 3-months (aOR=1.54; 95%CI=1.31-1.82). Women's heavy drinking was associated with increased HIV acquisition (aHR=3.71; 95%CI=0.90-15.25). Men's heavy drinking was associated with increased HIV acquisition (aHR=1.72; 95%CI=1.01-2.93), and transmission to women (aHR=1.42; 95%CI=0.97-2.10) compared to non-drinkers.
**Conclusions:** Alcohol consumption is a risk factor for outside sex partnerships, condomless sex and HIV acquisition in HIV-serodiscordant couples. Serodiscordant couples should be screened for and counseled about alcohol use risk.

## TUPEC193

### HIV INCIDENCE AND PREDICTORS OF HIV ACQUISITION FROM AN OUTSIDE PARTNER IN SERODISCORDANT COUPLES IN LUSAKA, ZAMBIA, 1995-2012

D. Joseph Davey[1], K. Wall[2], M. Inambao[3], W. Kilembe[3], I. Brill[4], E. Chomba[3], N. Htee Khu[3], J. Mulenga[3], B. Vwalika[3], A. Tichacek[2], S. Allen[2], L. Haddad[5]
*[1]University of Californa, Epidemiology, Los Angeles, United States, [2]Emory University, Atlanta, United States, [3]Rwanda-Zambia HIV Research Group, Lusaka, Zambia, [4]University of Alabama, Birmingham, United States, [5]Emory University, School of Medicine, Atlanta, United States*
*Presenting author email: lisa.haddad@emory.edu*

**Background:** There is limited research on the effect of fertility desire on HIV transmission and acquisition in sub-Saharan Africa. We evaluated the incidence and predictors of seroconversion from an outside partner among a long-running cohort of serodiscordant couples in Zambia.

**Methods:** Serodiscordant couples were enrolled from couples-counseling and testing sites in Lusaka, Zambia. Demographic, behavioral, and clinical exposures were measured. HIV-uninfected partners were re-tested every three-months. Genetic analysis classified incident infections as those acquired from the study partner (linked), or acquired from an outside partner (unlinked). Factors associated with time to unlinked HIV infection were evaluated using multivariable Cox models.

**Results:** Forty-five unlinked HIV infections occurred among women (1.58/100-couple-years [CY]; 95% CI=1.17, 2.10). Risk of female unlinked infection (relative to non-seroconverting couples) was associated with baseline female alcohol consumption (aHR=5.44; 95% CI=1.03, 28.73), recent genital ulcers and/or genital inflammation (aHR=6.09; 95% CI=2.72, 13.64 and aHR=11.92; 95% CI=5.60, 25.37, respectively). Reporting outside partner(s) was not associated with unlinked infection (aHR=2.07; 95% CI=0.42, 10.28) adjusting for woman's age, age disparity with partner, income, literacy, previous pregnancies, contraceptive use, and sperm present in vaginal swab. Fifty-five unlinked HIV infections occurred among men (1.63 per 100 couple years; 95% CI=1.24, 2.11). Risk of male unlinked HIV infection (relative to non-seroconverting couples) was associated with recent genital inflammation (aHR=8.52; 95% CI=3.82, 19.03), genital ulceration (aHR=4.27; 95% CI=2.05, 8.89), self-reporting =>1 outside partner (aHR=3.36; 95% CI=1.53, 7.37) versus none, and reporting being drunk weekly/daily at baseline (aHR=3.52; 95% CI=1.19, 10.46) vs. never, controlling for man's age, couple's income, male literacy, and male circumcision status.

**Conclusions:** The strongest predictors of unlinked infection in serodiscordant relationships were alcohol use, genital inflammation and ulceration prior to infection. Genital symptoms should be screened for and treated, or treated prophylactically for HIV-negative partners in serodiscordant couples. The risks of alcohol use should be included for both partners in risk-reduction counseling.

| | Adjusted Hazard Ratio (95% CI) |
|---|---|
| **MODEL 1: Female unlinked seroconversion* (Man HIV+ Woman HIV- couples, n=1393 couples)** | |
| **Time-varying** | |
| Genital inflammation in past 3 months (woman) | 11.92 (5.60, 25.37) |
| Genital ulcer in past 3 months (woman) | 6.09 (2.72, 13.64) |
| Self-report =>1 outside partner in past 3 months | 2.07 (0.42, 10.28) |

## TUPEC194

### HIV TRANSMISSION AMONG FOREIGN-BORN PEOPLE IN THE UNITED STATES

E. Valverde, A. Oster, S. Xu, J. Wertheim, A. Hernandez
*Centers for Disease Control and Prevention, Atlanta, United States*
*Presenting author email: fhu7@cdc.gov*

**Background:** In the United States, foreign-born persons are disproportionately affected by HIV and differ epidemiologically from U.S.-born persons diagnosed with HIV. Understanding HIV transmission dynamics among foreign-born persons is important to guide HIV prevention efforts for these populations. We conducted molecular transmission network analysis to describe HIV transmission dynamics among foreign-born persons diagnosed with HIV.

**Methods:** Using HIV-1 polymerase nucleotide sequences reported to the U.S. National HIV Surveillance System during 2001-2013, we calculated genetic distance, identified pairs of linked sequences (representing potential transmission partners) and examined place of birth (foreign-born vs. U.S.-born) and birth region of potential transmission partners.

**Results:** Of 77,686 HIV-1 nucleotide sequences, 12,074 (16%) were from foreign-born persons. Overall, 28% of foreign-born persons linked to at least one other person. Of these persons, 25% linked only to other foreign-born, 40% linked only to U.S.-born, and 35% linked to both other foreign-born and U.S.-born persons. A higher percentage of women (57%) and persons with infection attributable to heterosexual contact (50%) linked only with foreign-born persons. Only 19% of persons with infection attributable to male-to-male sexual contact linked only with foreign-born persons. The proportion of potential transmission partners born in the U.S. varied from 48%-79% by birth region (Figure). Persons born in Africa, the Caribbean, or Latin America shared the same birth region with most of their foreign-born potential transmission partners.

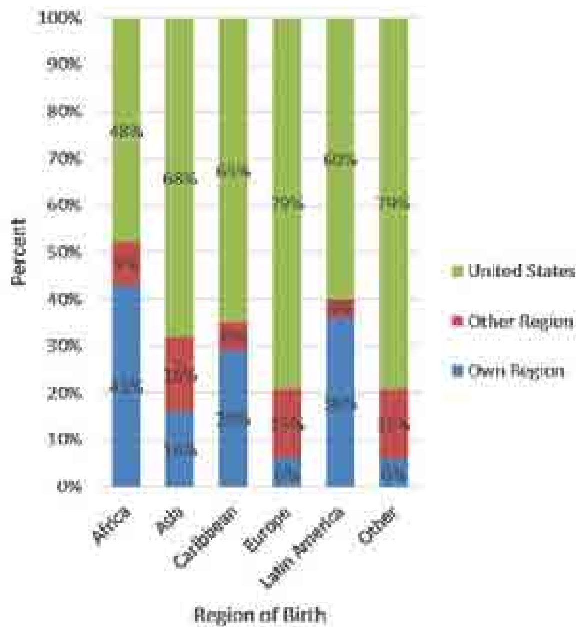
Author Index



*[Figure. Location of Birth of Potential Transmission Partners of HIV-Infected Foreign-Born Persons, United States]*

**Conclusions:** These data suggest that HIV transmission among foreign-born persons in the United States occurs primarily, but not exclusively, with U.S.-born persons, with important differences by key demographic and risk characteristics. HIV prevention efforts among persons born outside the U.S. should address the specific risk and distinct social aspects of populations from different regions of the world.

## TUPEC195

### DEFINING MIGRANTS AT RISK OF HIV IN EUROPE

B. Rice[1], V. Delpech[2], J. Hargreaves[1], J. Elford[3]
*[1]London School of Hygiene & Tropical Medicine, Public Health & Policy, London, United Kingdom, [2]Public Health England, London, United Kingdom, [3]City University London, London, United Kingdom*
*Presenting author email: brian.rice@lshtm.ac.uk*

**Background:** Many European countries consider migrants as an important sub-population in their response to HIV. Despite this, no common definition of a migrant is applied across Europe. We investigate ways of characterising migrant populations at risk of HIV infection in Europe which avoid promoting xenophobia and stigmatisation.

**Methods:** Computerised and manual literature searches were conducted. Key search terms included HIV, AIDS, migration, migrants, and Europe. Countries reporting a high number of new HIV diagnoses among migrants were also included as search terms. These included Denmark, France, Germany, Netherlands, Sweden, Switzerland, and the United Kingdom.

**Results:** Several definitions of migrants were identified which may provide a foundation for public health action. These included country of birth, ethnicity, nationality, and HIV sub-type. The advantages and disadvantages of each definition were considered. Country of birth was shown to highlight heterogeneity of risk according to national HIV prevalence but to mask variations in risk across country-specific sub-populations. Ethnicity was found to be commonly applied in public health research to highlight health inequalities but to group both non-European and European born persons in broad ethnicity categories. Nationality was found to have major limitations in studying the impact of migration on HIV. For example, a non-European born person obtaining citizenship within a European country will be, correctly, reported under their newly acquired nationality. The use of sub-type also had major limitations. Historically the identification of non-B subtypes has been interpreted as representing HIV-infection acquired outside of Europe. However, a number of recent studies have shown non-B subtypes to be prevalent among European born persons. Applied alone, none of the definitions clearly differentiated migrant populations at risk of HIV. Heterogeneity in risk of living with or acquiring HIV can be highlighted when broad ethnicity categories are presented in combination with country or world region of birth.

**Conclusions:** We identified several definitions of migrants which may provide a foundation for HIV public health action and, if applied sensitively, avoid negative stereotyping. We present evidence for the utility of categorising migrants according to both their ethnicity and country of birth to highlight heterogeneity in risk of acquiring or living with HIV.

## TUPEC196

### LABOR EXPLOITATION AND HIV/STI RISK AND INFECTION AMONG CENTRAL AMERICAN FEMALE MIGRANTS AT THE MEXICO-GUATEMALA BORDER

A. Servin[1,2], J. Silverman[3], S. Morales-Miranda[4], F. Chong Villareal[5], K. Brouwer[2]
*[1]University Xochicalco, School of Medicine, Tijuana, Mexico, [2]University of California, San Diego, Division of Global Public Health, La Jolla, United States, [3]University of California, San Diego, Center on Gender Equity and Health, La Jolla, United States, [4]Universidad del Valle de Guatemala, Centro de Estudios en Salud, Guatemala City, Guatemala, [5]El Colegio de la Frontera Sur, Tapachula, Mexico*
*Presenting author email: argentinanoelle@gmail.com*

**Background:** Recent reports indicate that increased migration across Central America north to Mexico and the US, is feeding human trafficking and labor exploitation. The International Labor Organization estimates that globally 20.9 million people have been trafficked for forced labor (mostly females), with domestic and agriculture work among the sectors of most concern. Labor exploitation often includes sexual violence. Sexual violence in the context of migration and sexual exploitation has been found to greatly elevate risk for HIV infection. However, to date limited studies have assessed the HIV risk among migrant women who are exploited for labor in this region.

**Methods:** This mixed methods study surveyed 200 migrant women ( identified via respondent-driven sampling (RDS) across 4 cities along the Mexico-Guatemala border from August 2012-September 2015. The questionnaire included:
1) socio-demographics,
2) labor exploitation,
3) sexual behavior and experiences (including exploitation and sexual violence), and
4) agricultural or domestic work history. 30 in-depth interviews (15 in each country) were conducted with migrant women screening positive for labor exploitation via the quantitative survey. Participants also underwent diagnostic testing for HIV and STIs.

**Results:** Of the women surveyed, 55.3% reported labor exploitation in the context of agricultural or domestic work in Mexico. Over half (66.8%) migrated as a child and started working prior to age 13. One in 8 participants reported sexual exploitation while working as an agricultural or domestic worker, 64.4% had no education beyond primary school and 14.1% entered sex work after working as an agricultural or domestic worker in Mexico. Of the overall sample 4.6% tested positive to HIV, 16.2% to Syphilis and 4.2% to HCV.

**Conclusions:** These findings contribute to the dearth of literature on an emerging and neglected social phenomenon. Future research is urgently needed to better understand the temporality and precise nature of observed relations between labor exploitation and HIV/STI risk and infection among migrant women including improving linkages to care in this region.

## TUPEC197

### HIV ACQUISITION POST-MIGRATION: EVIDENCE FROM FOUR EUROPEAN COUNTRIES

Z. Yin[1], B. Rice[2], G. Marrone[3], A. Sönnerborg[3], B. Suligoi[4], L. Camoni[4], A. Sasse[5], D. Van Beckhoven[5], A. Skingsley[1], T. Noori[6], V. Delpech[1]
*[1]Public Health England, HIV and STI Department, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, Measurement and Surveillance of HIV Epidemics (MeSH) Consortium, London, United Kingdom, [3]Karolinska Institute, Karolinska University Hospital, Department of Infectious Diseases, Stockholm, Sweden, [4]National Institute of Health, Department of Infectious Diseases, Rome, Italy, [5]Scientific Institute of Public Health, Brussels, Belgium, [6]European Centre for Disease Prevention and Control, Stockholm, Sweden*
*Presenting author email: valerie.delpech@phe.gov.uk*

**Background:** Two in five people living with HIV in Europe were born outside of the European country where they were first diagnosed. However, there may be a misplaced belief that acquisition has predominantly occurred in the home country. To better inform prevention and testing programs, we provide country-specific estimates of the proportion of migrants who probably acquired HIV after arrival in their country of diagnosis (post-migration).

**Methods:** We analysed new HIV-diagnosis reports among migrants (defined by country of birth/origin) diagnosed in the United Kingdom (UK), Belgium, Sweden and Italy in 2011. We estimated a probable period of HIV seroconversion using modelled CD4-cell count distribution and decline speed shortly after seroconversion. A migrant was classified as having acquired HIV 'post-migration' or 'abroad', or 'overlapped' when the estimated period of seroconversion was 'after', 'before' or 'overlapped with' the year of arrival. At the population level, a lower estimate of the proportion of migrants having acquired HIV post-migration was gained when only those classified as 'post-migration' were included; an upper estimate includes both those classified as 'post-migration' and 'overlapped'; and a central estimate was gained when the 'overlapped' were reassigned to either 'post-migration' or 'abroad' based on estimated median CD4-cell count and decline speed.

**Results:** 2,351 migrants were recruited (1,683 UK, 329 Belgium, 185 Sweden and 154 Italy). In all countries, the majority were aged 25-44 years (>70%), heterosexual (>70%) and born in Africa (>60%). Overall, an estimated 38% (range: 32-46%) of diagnosed migrants had probably acquired HIV post-migration. The UK had the highest proportion 43% (range: 36-52%) followed by Belgium 29% (26-34%), Sweden 24% (21-30%) and Italy 23% (20-27%). An estimated 42% (203/481; 38-50%) of men who have sex with men probably acquired HIV post-migration compared to 38% (658/1,713; 32-47%) among heterosexual people.
**Conclusions:** We present for the first time multi-country estimates of probable place of HIV-acquisition among migrants living with HIV in Europe. More than a third of migrants diagnosed in these four European countries acquired HIV post-migration, and this proportion was high in MSM and heterosexuals. Our findings call for targeted prevention efforts to reduce HIV transmission among the migrant populations within Europe.

## Epidemiology of HIV in transgender persons

### TUPEC198

### Global HIV epidemiology among trans populations: new data, unique vulnerabilities

T. Poteat[1], A. Scheim[2], S. Reisner[3], J. Xavier[4], S. Baral[1]
*[1]Johns Hopkins School of Public Health, Epidemiology, Baltimore, United States, [2]Western University, London, Canada, [3]Boston Children's Hospital and Harvard Medical School, Boston, United States, [4]Health Resources Services Administration, Bethesda, United States*

**Background:** The rapid increase in research on transgender (trans) populations necessitates an update of global HIV data. Stigma is a significant determinant of health and may drive syndemics of HIV in trans populations. This review synthesizes the most recent epidemiology of HIV and related syndemics in trans populations, describes current gaps in HIV-related research and interventions with trans populations, and makes recommendations to improve the effectiveness of HIV prevention, treatment, and care programs.
**Methods:** A systematic review was conducted of manuscripts and abstracts published between January 1, 2012 and November 30, 2015. Experts in HIV among transgender populations were contacted for unpublished HIV prevalence data meeting other inclusion criteria. Title and abstract reviews for relevance were conducted on unduplicated references independently by two reviewers, with subsequent full-text review for data abstraction. Studies with original quantitative HIV data that disaggregated transgender participants from other populations were included. Laboratory-confirmed HIV data are presented.
**Results:** Estimates varied dramatically by location and participant characteristics. In 8 studies in the United States, HIV prevalence in trans feminine individuals ranged from 2.0% in an HIV testing program to 40.1% among sex workers. In 10 Latin American studies, prevalence ranged from 12%-34.1%; In 7 Asian studies, prevalence ranged from 0% in a small RDS sample (n=23) to 45.2% in an urban STI clinic. Among 8 studies with trans masculine people, prevalence ranged 0%-4.3% with the highest estimate in those seeking STI screening. See table for summary of syndemics in trans populations.

[illegible]

*[Summary of studies examining syndemic production of HIV in trans populations, 2012-15]*

**Conclusions:** Trans feminine individuals continue to bear one of the highest burdens of HIV in the world. Data on trans masculine individuals are limited, but suggest potential risk for individuals with non-trans male partners. Addressing HIV-related syndemics and transgender-specific challenges will be critical to ensuring engagement and retention in HIV care and treatment by this very vulnerable population.

### TUPEC199

### High prevalence of HIV and syphilis among transgender women in Vietnam

D. Colby[1,2], T. Trang[2], B. Le[2], T.D. Dinh[2], Q.H. Nguyen[2], H.T. Hoang[2], M. Freeman[3], R. Stall[3]
*[1]Thai Red Cross AIDS Research Centre, SEARCH, Bangkok, Thailand, [2]CARMAH, Ho Chi Minh, Vietnam, [3]University of Pittsburgh, Pittsburgh, United States*
*Presenting author email: doctordonn@gmail.com*

**Background:** Transgender women (TGW) have high risk for HIV infection, exacerbated by stigma, discrimination, and gender-based violence. This is the first bio-behavioral survey of TGW in Vietnam.
**Methods:** A cross-sectional study was performed in Ho Chi Minh City (HCMC) during March-April, 2015. Inclusion criteria were > 18 years old, biological male at birth, self-identified as transgender, and able to give informed consent. TGW were recruited by chain-referral methods using existing social networks. Participants completed a standardized questionnaire and had blood drawn for HIV and syphilis serology.
**Results:** A total of 205 TGW, median aged 25 (range 18-64) years, completed the survey. Hormone use was reported by 67%, of which 88% had used injectable hormones and only 2% were prescribed by a physician. High-risk sexual behavior was common: 35% reported sex work in the previous month, 12% purchased sex form male sex workers, 31% reported inconsistent condom use with clients and casual partners, and 14% used amphetamines in the previous month. Overall, 99.5% had ever had sex with male partners and 3.4% had sex with female partners. Prevalence of HIV was 18% (37/205) and syphilis was 17.6% (36/205). Only one TGW with HIV infection was previously aware of her status. On multivariable analysis, the two factors significantly associated with HIV infection were buying sex from male sex workers (aOR 4.0, 95% CI 1.4-11.4) and amphetamine use in the previous month (aOR 2.9, 95% CI 1.3-6.6).
**Conclusions:** TGW in HCMC engage in high-risk behavior and have a high prevalence of HIV infection. No HIV prevention programs in Vietnam specifically target TGW. Existing programs that serve the population of men who have sex with men may fail to engage with TGW. Targeted interventions are needed to provide HIV prevention education, HIV counseling and testing, and screening and treatment for sexually transmitted infections to Vietnamese TGW.

## Epidemiology of HIV in other populations

### TUPEC200

### People with disabilities are at increased risk of HIV infection and adverse sexual health outcomes: results from the HandiVIH study (ANRS 12302)

P. De Beaudrap[1], E. Pasquier[2,3], F. Essomba[3], A. Touko[4], A. Tchoumkeu[3], A. Brus[5], M. Mac-Seing[5], G. Beninguisse[3]
*[1]Institut de Recherche pour le Développement (IRD), Ceped - UMR 196, Paris, France, [2]Expertise France, 5% Initiative HIV-TB-Malaria, Paris, France, [3]Institut de Formation et de Recherche Démographique (IFORD), Yaoundé, Cameroon, [4]Forum Camerounais de Psychologie (FOCAP), Yaoundé, Cameroon, [5]Handicap International, Lyon, France*
*Presenting author email: pierre.debeaudrap@ird.fr*

**Background:** Although people with disabilities (PWD) living in resource-limited countries seem to be particularly vulnerable to HIV infection, they have often been left behind in the HIV response probably due to lack of reliable epidemiological data measuring their vulnerability. The HandiVIH study aimed to document the vulnerability of PWD to HIV, and to compare their situation to that of people without disabilities in Yaounde (Cameroon).
**Methods:** This cross-sectional survey conducted in 2015 used a two-phase random sampling to recruit adults with disabilities and controls matched for age, sex and residential location from the general population using the Washington Group Disability questionnaire. An HIV test and a life-course history interview were proposed to participants. The analysis uses conditional (fixed-effects) and unconditional logistic regressions.
**Results:** A total of 807 PWD and 807 controls (52% of women) were included. Among PWD, 23%, 12%, 43% and 21% had visual, hearing, physical and intellectual and/or mental limitations respectively. The proportion of subjects sexually active

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July

Author Index

was similar among those with physical or visual impairments and their controls (91% vs 92%, p=0.8). However, it was lower among those with intellectual and/or mental impairments (52% vs 87% in controls, p< 0.001). The level of knowledge on HIV was lower among PWD (p< 0.001). However, this difference was no more significant after adjusting for education (p=0.1).
HIV test results were available for 90% of the subjects. The overall crude HIV prevalence was 3.9%, 95%CI:2.9-5.3 among controls and 6.5%, 95%CI: 4.7-8.3 among PWD (OR=1.67, p=0.05).
Compared to controls, women with disabilities were more frequently involved in sexual relationships in exchange for money (2.46% vs 0.72%, p=0.05). Besides, PWD - especially women - were at increased risk of sexual violence (OR=1.5, p=0.02). The proportion of condom use with casual partner was lower among PWD compared to controls (62% vs 78%, p=0.05) and was associated to the lower education level (p=0.004) and higher rate of sexual violence observed in this group (p=0.004).
**Conclusions:** This study shows that PWD are at increased risk of HIV and of other negative sexual outcomes including sexual violence. Effective preventive interventions are urgent to protect one of the world's largest minorities.

## TUPEC201

### ADHERENCE AND VIRAL FAILURE IN ASYMPTOMATIC PATIENTS STARTING ART: THE SWISS HIV COHORT STUDY

T. Glass[1], M. Battegay[2], M. Cavassini[3], A. Calmy[4], E. Bernasconi[5], H. Günthard[6], P. Schmid[7], H. Furrer[8], Swiss HIV Cohort Study
*[1]Swiss Tropical and Public Health Institute, Biostatistics, Basel, Switzerland, [2]University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland, [3]University Hosptial Lausanne, Division of Infections Diseases, Lausanne, Switzerland, [4]University Hospital Geneva, Division of Infections Diseases, Geneva, Switzerland, [5]Ospedale Civico Lugano, Division of Infections Diseases, Lugano, Switzerland, [6]University Hospital Zurich, Division of Infectious Diseases and Hospital Epidemiology, Zurich, Switzerland, [7]Kantonsspital St. Gallen, Division of Infections Diseases, St. Gallen, Switzerland, [8]University Hospital Bern, Division of Infections Diseases, Bern, Switzerland*
*Presenting author email: tracy.glass@unibas.ch*

**Background:** In response to the TEMPRANO and START trials, the WHO recommended in November 2015 that HIV-infected individuals should begin ART regardless of CD4 cell count. A higher share of individuals initiating ART will be asymptomatic with a preserved immune system. We aimed to explore adherence patterns and clinical outcomes in patients starting ART according to symptom status.
**Methods:** All ART-naïve patients aged ≥18 years, not pregnant, starting ART between January 2003 and July 2014, followed for ≥1 year and completing ≥1 adherence questionnaire were included. Asymptomatic was defined as CDC-stage A at the time of starting ART. Self-reported missed doses in the last 4 weeks were recorded at each clinical visit. Viral failure was defined as RNA viral load>500 copies/ml after > 24 weeks on ART. Cox proportional hazard models were used to assess the association between symptom status and viral rebound.
**Results:** 3457 patients were included. Overall, 2458 (71.1%) individuals were asymptomatic when starting ART with the percentage increasing over time from 49% in 2003 to 85% in 2014 (median CD4 cell count 228 (IQR: 151-359) and 355 (IQR: 215-514) cells/μl, respectively). Individuals starting ART when asymptomatic were more often male, younger, better educated and reporting having unsafe sex. Adherence to ART was significantly better in asymptomatic compared to symptomatic patients with missed doses reported in 48% and 55% of patients, respectively (p< 0.001). Overall, 581 individuals (17%) experienced viral rebound a median of 1.6 years (IQR: 0.8-3) after starting ART and 35% of failures occurred in the first year on ART. The rate of viral rebound was significantly lower in asymptomatic patients (14.8% versus 22.4%, p< 0.001). In survival models adjusting for socio-demographic and treatment variables, starting ART when asymptomatic was an independent predictor of a reduced hazard for viral failure (hazard ratio: 0.83, 95% CI: 0.69-1.00).
**Conclusions:** In the era prior to 'test and treat', choosing to start ART when asymptomatic had a positive effect and was associated with better adherence and lower rates of viral failure. However, under current guidelines where asymptomatic patients are recommended to start ART, the question of readiness may become more important.

# EPIDEMIOLOGY OF TB AND HIV CO-INFECTION

## TUPEC202

### HIV IN ACUTE CARE: A REVIEW OF THE BURDEN OF HIV- ASSOCIATED PRESENTATIONS TO AN EMERGENCY DEPARTMENT

B. Naicker, R. Maharaj
*UKZN, Division of Emergency Medicine, Durban, South Africa*
*Presenting author email: bnikeair@yahoo.com*

**Background:** Human immunodeficiency virus (HIV) is a leading cause of morbidity and mortality in sub-Saharan Africa. Our objective was to determine the burden of HIV disease and its co-infection on a district-level Emergency Department (ED) in KwaZulu-Natal.
**Methods:** A retrospective study over a 3 month period identifying patients presenting with HIV and its complications was conducted. Patient demographics, disease presentation, severity of illness, investigations performed and disposition of patients were assessed.
**Results:** 428 of the 861 (49.7%) medical patients presenting to the ED were HIV positive. 37% of patients were unaware their HIV status. In the HIV-positive cohort, the median age of presentation was 37 years, with almost equal male-to-female distribution. 57.5% were referred and 68% of patients presented after hours. More than 80% of patients were triaged as high acuity cases. The predominant systems involved were the respiratory and central nervous systems, with pulmonary tuberculosis, community-acquired pneumonia and meningitis being the most common diagnoses. X-rays and laboratory testing were the most common investigations requested. Lumbar punctures, pleural paracentesis and pericardiocentesis were common emergency procedures performed. The majority (89.3%) of patients were admitted to the medical ward. Of the HIV-positive patients, 33% were on anti-retroviral therapy. ED mortality was 1.9%.
**Conclusions:** This study highlights the significant impact HIV places on the resources of an ED. Strengthening of the primary health care system with a more aggressive approach to HIV testing and ARV initiation may contribute positively to reducing the burden of HIV emergencies and comorbidities presenting to the ED.

## TUPEC203

### THE DIFFERENTIAL IMPACT OF HIV AND ART ON GENDER- AND AGE-SPECIFIC TUBERCULOSIS RATES

S.M. Hermans[1,2,3], K. Middelkoop[1,4], M. Cornell[5], R. Wood[1,4,6]
*[1]Desmond Tutu HIV Centre, Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa, [2]Amsterdam Insititue for Global Health and Development, Department of Global Health, University of Amsterdam, Amsterdam, Netherlands, [3]School of Medicine, Makerere University College of Health Sciences, Department of Internal Medicine, Kampala, Uganda, [4]University of Cape Town, Department of Medicine, Cape Town, South Africa, [5]School of Public Health and Family Medicine, University of Cape Town, Cape Town, South Africa, [6]Faculty of Infectious & Tropical Diseases, London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom*
*Presenting author email: s.hermans@aighd.org*

**Background:** Tuberculosis (TB) rates are higher among men than women, which is thought to be due to social and/or biological differences. Cape Town has a very high burden of TB and HIV. We aimed to investigate the changes in gender and age-specific TB rates, HIV-associated risk of TB and the population attributable risk fraction (PAF) of HIV over time in Cape Town since the onset of the HIV epidemic and the roll-out of antiretroviral therapy (ART).
**Methods:** We used annual TB notifications from the Medical Officer of Health reports (1993) and the metropolitan electronic TB register (2003-2014), and mid-year population estimates from Statistics South Africa. HIV prevalence estimates were sourced from the Actuarial Society of South Africa Western Cape AIDS model 2008. TB notification rates were calculated per 100,000 population and stratified by gender, 10-year age group and HIV status. Annual rate ratios (RR) of TB associated with HIV infection and the annual PAF were calculated by gender.
**Results:** In 1993, TB rates were higher among men than women (146/100,000 versus 247/100,000). By 2009, TB rates increased 5.2-fold (to 758/100,000) among women and 3.7-fold (to 922/100,000) among men. Thereafter TB rates declined by 26% and 16%, respectively. In the HIV-era TB rates peaked at a younger age in women than in men (25-34 versus 35-44 years). The RR of TB associated with HIV infection was 30% higher in women than in men in 2003 (28 versus 17), but decreased to equalisation in 2013 (15 versus 16). More TB disease was attributable to HIV among women than men (53% versus 35% in 2003, 49% versus 37% in 2014).
**Conclusions:** The HIV epidemic led to a greater increase in TB rates among women than men, in keeping with the higher HIV burden among women. Nevertheless, TB rates among men remained higher. HIV infection was associated with higher rates

of TB in women than men early in the epidemic suggesting HIV removed the protective effect of gender. The recent declining difference is likely caused by differential access to ART. Despite this encouraging trend, TB control programmes need to focus on TB prevention and treatment among young women.

## Epidemiology of sexually transmitted infections (STI) and HIV co-infection

### TUPEC204

#### Sexually transmitted infections (STI) and HIV co-infection among youth living in the slums of Kampala, Uganda

R. Culbreth[1], M. Swahn[1], L. Salazar[1], R. Kasirye[2]
*[1]Georgia State University, School of Public Health, Atlanta, United States, [2]Uganda Youth Development Link, Kampala, Uganda*
*Presenting author email: mswahn@gsu.edu*

**Background:** The prevalence of co-infection with sexually transmitted infections (STI's) and HIV is high worldwide, particularly in sub-Saharan Africa. Certain STI's increase the risk of acquisition of HIV. However, little is known about HIV/STI co-infection among high-risk groups in sub-Saharan Africa, particularly among vulnerable youth. The objective of this study was to assess the risk and protective factors associated with HIV/STI co-infection among youth living in the slums of Kampala, Uganda.
**Methods:** Analyses are based on cross-sectional survey data collected in March 2014. Participants comprised a convenience sample (N=1,134) of urban service-seeking youth living on the streets or in the slums, 12-18 years of age who were participating in a Uganda Youth Development Link drop-in center (56.1% female and 43.9% male). Multinomial logistic regression was used to determine factors (gender, age, education, condom use, alcohol use, and sex work) associated with reporting HIV/STI co-infection, HIV only, STI only, and neither HIV/STI. IRB approvals were obtained from the Georgia State University and the Uganda National Council for Science and Technology.
**Results:** Among youth who had ever had sex, the self-reported HIV prevalence was 13.2%, and the prevalence of HIV/STI co-infection was 9.9%. STI only prevalence was 42.8%. Among youth who reported HIV/STI co-infection, the majority were female (74.1%) and 18 years old (51.7%). HIV/STI co-infection was associated with being female (AOR 2.08; 95% CI: 1.04, 4.15), alcohol use in the previous 12 months (AOR 2.83; 95% CI: 1.43, 5.59), and engaging in sex work (AOR: 2.78; 95% CI: 1.19, 6.49) compared to the absence of HIV/STI. Compared to HIV infection alone, HIV/STI co-infection was associated with being female (AOR: 5.00; 95% CI: 1.62, 15.36). Alcohol use in the past 12 months was also associated with having an STI only (AOR 1.73; 95% CI: 1.17, 2.56) compared to the absence of HIV/STI.
**Conclusions:** Youth living in the slums of Kampala, Uganda have a high prevalence of HIV/STD co-infection. HIV/STD co-infection was also associated with modifiable risk factors that could be addressed to reduce further health complications of their existing health conditions.

### TUPEC205

#### HSV-1 and HSV-2 are associated with HIV seropositive status among young gay, bisexual, and other men who have sex with men: preliminary findings from the P18 cohort

D. Ompad[1,2,3], F. Kapadia[1,2,3], R. Greene[2,4,5], P. Halkitis[1,2,3]
*[1]New York University, College of Global Public Health, New York, United States, [2]New York University, Center for Health, Identity, Behavior and Prevention Studies, New York, United States, [3]New York University, Center for Drug Use and HIV Research, New York, United States, [4]New York University School of Medicine, Department of Medicine, New York, United States, [5]Bellevue Adult Primary Care Center, New York, United States*
*Presenting author email: dco2@nyu.edu*

**Background:** There is a strong and consistent relationship between HIV and herpes simplex virus (HSV)-2. Previous analyses from the P18 cohort document racial disparities in HIV incidence for black and multirace/other race YMSM. Disparities in HIV burden may be attributable, in part, to HSV-2. Less understood, however, is the relationship between HSV-1 and HIV. This relationship is of particular interest given the higher prevalence of HSV-1 vs. HSV-2 as well as virological and pathological similarities HSV-1 and HSV-2.
**Methods:** P18 is an ongoing prospective cohort study of young gay, bisexual, and other men who have sex with men (YMSM) in New York City. At each semi-annual visit, men complete risk assessment surveys and undergo HIV testing. Beginning in October 2015, serologic testing for HSV-1 and HSV-2 was added to the 54-month visit. To date, 108 men have complete data on HSV and HIV.
**Results:** The mean age of the sample is 23.6 years (range 22-25). Most were male-(91.4%) and gay-identified (83.7%); 44.3% were Hispanic/Latino, 28.3% were black, 8.5% were white, 7.6% were Asian/Pacific Islander, and 11.3% other race. HIV prevalence was 12.7%. Prevalence of any HSV was 65.7%; 41.7% had HSV-1 only, 12.0% had HSV-2 only, and 12.0% were co-infected with HSV-1 and HSV-2. All 14 HIV+ men were co-infected with at least one HSV-type; 35.7% had HSV-1 only, 21.4% had HSV-2 only, and 42.9% were co-infected with HSV-1 and HSV-2. In a multivariate logistic regression model, both HSV-1 and HSV-2 were associated with increased odds for HIV (HSV-1 AOR=5.1, 95% CI=1.2, 22.1 and HSV-2 AOR=10.3, 95% CI=2.8, 37.7). Race/ethnicity was not associated with HSV-2 infection alone, but blacks were significantly more likely to have HSV-1 (OR=3.1, 95% CI=1.1, 8.7) and HSV-1 or HSV-2 as compared to Hispanics
(OR=4.0, 95% CI=1.2, 13.5).
**Conclusions:** These preliminary cross-sectional data suggest that both HSV-1 and HSV-2 are associated with HIV infection among YMSM and that there may be racial disparities in HSV prevalence. HSV may lead to HIV especially since it often goes undiagnosed. Prospective studies are needed to determine whether both HSV-1 and HSV-2 increase risk for HIV acquisition.

### TUPEC206

#### Explaining the heterogeneity in the prevalence of gonorrhea across the Middle East and North Africa: meta-regression analyses

A. Smolak, L.J. Abu-Raddad
*Weill Cornell Medicine-Qatar, Infectious Disease Epidemiology Group, Doha, Qatar*
*Presenting author email: as3234@columbia.edu*

**Background:** A recent systematic review of the epidemiology of Neisseria gonorrhoeae (NG) in the Middle East and North Africa (MENA) region found substantial heterogeneity across studies. Our aim was to identify sources of heterogeneity in NG prevalence and quantify their contribution to the increased odds of infection across MENA. Gonorrhea can be valuable to consider in the context of HIV as it can increase risk of HIV transmission and can offer some indicator of populations at greater risk for HIV.
**Methods:** We assessed the individual contributions of five potential sources of heterogeneity—the population's risk of exposure to NG, type of assay, sample size, publication date, country, and sex—to higher odds of NG. Factors identified as significant in the univariable analysis (p-value< 0.1) were incorporated in a random effects multivariable meta-regression model where their respective contributions to the increased odds of NG were quantified using adjusted odds ratios (aOR) and 95% confidence intervals (95% CI).
**Results:** Our univariable meta-regression analyses showed significant associations between increased odds of NG and all potential sources of heterogeneity except for publication date. Our multivariable meta-regression model indicated that population's risk of exposure to NG and sample size were significantly associated with NG prevalence: high risk populations (aOR: 6.71, 95% CI: 2.94-15.33), infertility clinic attendees (aOR: 6.21, 95% CI: 1.91-20.16), symptomatic males (aOR: 62.24, 95% CI: 19.65-197.15), and symptomatic females (aOR: 1.96, 95% CI: 1.07-3.62) had higher odds of NG compared to the general population. Studies with less than 200 participants had higher odds of NG than those with a larger sample size (aOR: 1.77, 95% CI: 1.07-2.92). The amount of heterogeneity explained by the multivariable meta-regression model as indicated by the adjusted $R^2$ was 63.58%.
**Conclusions:** Our study identified population and study-related factors associated with NG prevalence in MENA. These findings highlight the need for prioritizing programs for high risk populations, and for an in-depth assessment of a possible link between NG infection and infertility. Further research aimed at characterizing better NG epidemiology and disease burden in MENA, and its link to HIV is warranted.

### THE SPECTRUM MODEL ESTIMATING NATIONAL SYPHILIS AND GONORRHEA PREVALENCE & TRENDS: RESULTS FOR 10 LOW- AND MIDDLE-INCOME COUNTRIES, AND IMPLICATIONS FOR STRENGTHENING STI SURVEILLANCE

E. Korenromp[1], G. Mahiané[2], N. Nagelkerke[3], J. Rowley[4], L. Abu-Raddad[5], F. Ndowa[6], P. Mayaud[7], R.M. Chico[7], R. Steen[8], C. Pretorius[2], J. Stover[2], T. Wi[9]

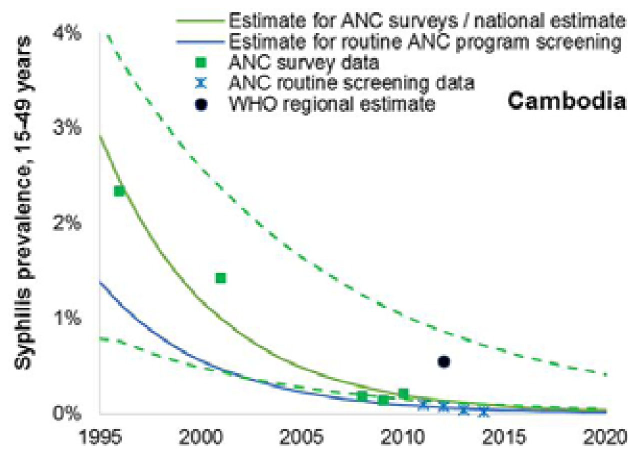
*[1]Avenir Health, Modelling and Policy Analysis, Geneva, Switzerland, [2]Avenir Health, Modelling and Policy Analysis, Glastonbury, United States, [3]Malawi-Liverpool Wellcome Trust, Blantyre, Malawi, [4]NA, London, United Kingdom, [5]Weill Cornell Medical College, Qatar, Qatar, [6]Skin & GU Medicine Clinic, Harare, Zimbabwe, [7]London School of Hygiene and Tropical Medicine, London, United Kingdom, [8]Erasmus MC, University Medical Center Rotterdam, Public Health, Rotterdam, Netherlands, [9]World Health Organization, Reproductive Health and Research, Geneva, Switzerland*

*Presenting author email: jstover@avenirhealth.org*

**Background:** Estimates of population-level burdens and trends in Sexually Transmitted Infections (STIs) are important to underpin STI control strategies, programs and resource mobilization, and could inform HIV/AIDS surveillance. We developed the first-ever standardized method estimating trends in gonorrhea and active syphilis, anchored on countries' annual indicator reporting through the Global AIDS Response Progress Reporting System.

**Methods:** Gonorrhea prevalence levels and trends were fitted on general adult population prevalence surveys (from the country, neighboring countries and regional estimates; as a moving average, weighting country-owned data heaviest), with trends informed additionally by laboratory-diagnosed gonorrhea and/or urethral discharge case reports where judged of reasonably stable completeness. Syphilis prevalence trends were fitted through logistic regression for pregnant women attending antenatal clinics (two-yearly sentinel surveys, and increasingly routine programmatic screening), weighting each data point by its national coverage and representativeness. Prevalences were adjusted for diagnostic test performance, missing high-risk populations, urban/rural and male/female differences, using WHO's assumptions from recent global and regional-level estimations. Uncertainty intervals were obtained by bootstrap resampling.

**Results:** Across Namibia, Zimbabwe, Morocco, Cambodia, Sri Lanka, Indonesia, Cuba, Bolivia, Peru and Mongolia, estimated national gonorrhea prevalences in 15-49 years ranged from 0.49%-7.5% in 2000 and 0.71-6.9% in 2015. Syphilis prevalences were 0.03-6.1% in 2000, and 0.08-4.3% in 2015. Over 2000-2015 estimated syphilis prevalence had declined in 8 countries (by on average 45%), and increased in two. For gonorrhea, time trends were less certain.



*[Syphilis prevalence estimation Cambodia_AvenirHealth pilot_03Feb2016]*

**Conclusions:** Country-level syphilis trends and burdens can be estimated based on surveillance and program data, but for gonorrhea rely on non-routine prevalence surveys. Provisional estimates could be improved by national HIV/STI strategic information experts validating and updating input data. The estimation method will be integrated in the Spectrum suite of health estimation and strategic planning projection tools, informing existing Spectrum modules estimating HIV/AIDS trends and program impacts.

## TUPEC208

### HIGH PREVALENCE OF SEXUALLY TRANSMITTED INFECTIONS IN A COHORT OF SOUTH AFRICAN MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN FROM PORT ELIZABETH AND CAPE TOWN, SOUTH AFRICA

R. Zahn[1], K. Dominguez[2], T. Sanchez[1], N. Phaswana-Mafuya[3,4], L.-G. Bekker[2], S. Baral[5], R. Kearns[1], C. Yah[3,4], P. Sullivan[1]

*[1]Emory University Rollins School of Public Health, Atlanta, United States, [2]The Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [3]Human Sciences Research Council, Port Elizabeth, South Africa, [4]Nelson Mandela Metropolitan University, Port Elizabeth, South Africa, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States*

*Presenting author email: rzahn@emory.edu*

**Background:** Though there is little research describing sexually transmitted infection (STI) prevalence among men who have sex with men (MSM) and transgender women (transwomen) in Africa, previous models suggest that an effective comprehensive HIV prevention strategy for this group requires diagnosing and treating STIs.

**Methods:** The Sibanye Health Project is a one-year prospective study of combination HIV prevention among MSM/transwomen from Port Elizabeth and Cape Town, South Africa. The study conducts baseline screening for prevalent HIV infection, syphilis, gonorrhea and chlamydia. We describe overall STI prevalence by organism and site of infection (urethral/rectal) and stratified by age, city, and HIV status.

**Results:** From February to September 2015, we enrolled 292 MSM and transwomen, of whom 125 (43%) were living with HIV infection. At baseline, 124 participants (42%) had any type of STI, 34 (12%) had a urethral STI and 60 (31%) had a rectal STI (see Table). Rectal STIs were found in 57% of participants 18-19 years and significantly decreased with older age. Compared to HIV-negative persons, those living with HIV infection were more likely to have had syphilis but were less likely to have had urethral Chlamydia. Of those with a biologically-confirmed STI, 8% (10/124) had a symptomatic STI diagnosis during the clinical assessment.

*[Sexually Transmitted Infections among Men Who have Sex with Men and Transwomen, Sibanye Health Project]*

**Conclusions:** Biologically-confirmed STI prevalence is high in this cohort of MSM/transwomen from South Africa, particularly rectal STIs among the youngest groups. The associations between STIs and HIV status may be due to differences in underlying sexual risk behaviors or previous screening/treatment. A comprehensive HIV prevention strategy for MSM/transwomen should include a full set of STI screening - including rectal - and treatment when indicated. These data further suggest that reliance on syndromic surveillance for STI would have missed more than 90% of these infections, highlighting the need for presumptive testing or even presumptive treatment for those at highest risk.

## TUPEC209

### HIGH RATES OF SEXUALLY TRANSMITTED INFECTIONS: RESULTS FROM THE POPULATION-BASED HOUSEHOLD SURVEY IN KWAZULU-NATAL, SOUTH AFRICA

L. McKinnon[1,2], A.B.M. Kharsany[1], C. Cawood[3], D. Khanyile[3], A. Grobler[1], T. Goodman[1,4], L. Madurai[5], V. Maseko[6]

*[1]CAPRISA, Durban, South Africa, [2]University of Manitoba, Winnipeg, Canada, [3]Epicentre AIDS Risk Management (Pty) Limited, Cape Town, South Africa, [4]Columbia University, New York City, United States, [5]Global Clinical and Virology Laboratory, Amanzimtoti, South Africa, [6]Centre for HIV and STIs, National Institute for Communicable Diseases, National Health Laboratory Service (NICD/NHLS), Johannesburg, South Africa*

*Presenting author email: lyle.mckinnon@caprisa.org*

**Background:** South Africa has a high burden of HIV and sexually transmitted infections (STI), with the province of KwaZulu-Natal (KZN) particularly affected by both epidemics. STIs have been associated with adverse reproductive health outcomes and contribute to an increased risk of HIV acquisition and transmission. Whilst STI data are available from select populations, there is little information on population level prevalence.

We assessed the prevalence of STIs among participants enrolled in the HIV Incidence Provincial Surveillance System (HIPSS), a population based-household survey conducted in the Vulindlela and Greater Edendale sub-districts of uMgungundlovu District, KwaZulu-Natal, South Africa.
**Methods:** In addition to completing a questionnaire, participants aged 15-49 years provided clinical specimens including peripheral blood, first-pass urine (males), and self-collected vulvo-vaginal swab samples (females). STIs included *Neisseria gonorrhoeae* (NG), *Chlamydia trachomatis* (CT), *Trichomonas vaginalis* (TV) and *Mycoplasma genitalium* (MG) (by multiplex PCR of swabs or urine). Sera were tested for evidence of syphilis infection using non-treponemal rapid plasma reagin (RPR) assay and for herpes simplex virus type 2 (HSV-2) antibodies by enzyme-linked immunosorbent assay.
**Results:** More than one-third of the 9812 participants were under the age of 25, and two-thirds were females. Prevalence of all STIs was higher in women than men with the exception of *M. genitalium*, and all STIs were more common in HIV-infected individuals apart from *C. trachomatis*. HSV-2 antibodies was prevalent in 63% of participants (72% of females and 46% of males, p< 0.001). Syphilis antibodies were prevalent in 2.9% (3.1% in females and 2.5% in males). *N. gonorrhoeae, C. trachomatis*, and *M. genitalium* were present in 3.0%, 7.6%, and 5.4% of participants, respectively. Each reached peak prevalence in women aged 20-24 (6.2%, 15.1%, and 8.5% for NG, CT, and MG, respectively), whereas for men this peak prevalence occurred at age 25-29 (and 30-34 for MG). *T. vaginalis* was detected in 11.7% of participants, with a prevalence of 15.9% in females and 4.3% in males.
**Conclusions:** STIs are common in this population-based survey of a high HIV burden region. Strategies to better diagnose and manage these infections are urgently needed.

## TUPEC210

### Anogenital HPV infection and associated disease in HIV-positive men in Johannesburg, South Africa

A. Chikandiwa[1], L. Chimoyi[1], P.T. Pisa[1], P. Michelow[2], P. Mayaud[1,3], S. Delany-Moretlwe[1]
*[1]Wits RHI, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Cytology Unit, National Health Laboratory Service and Dept of Anatomical Pathology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom*
*Presenting author email: achikandiwa@wrhi.ac.za*

**Background:** Persistent high-risk human papillomavirus (HR-HPV) infection is associated with anogenital and oropharyngeal cancers in men, particularly in men living with HIV/AIDS (MLWHA). We report on baseline results of a prospective study in MLWHA to determine the influence of HIV on the burden and natural history anogenital HPV infection and disease.
**Methods:** We enrolled 304 sexually active consenting MLHA ≥18 years. Socio-behavioral data was collected by questionnaire. Trained clinicians examined for anogenital warts (AGWs), collected blood (CD4+ counts and HIV viral load [VL]), genital (n=283), anal (n=227) swabs for HPV DNA (Roche Linear Array) and anal smears. Factors associated with anogenital disease were assessed by logistic regression.
**Results:** Participants median age was 38 (IQR 10) years. Most (65%) participants were on ART with a median duration of 33 (IQR 42) months, and 20% of those on ART for > 12 months had undetectable VL (i.e. < 40 copies/ml). Among those with anogenital swab results, 79% had HPV detectable, 52% had HR-HPV and 64% had LR-HPV. The prevalence of AGWs was 12%. Infection with HPV 6 [aOR=3.79 (1.4-9.9), ≥1 LR types [aOR=42.67 (14.06-129.48)] and being ≤ 6 months on ART [aOR=6.56 (1.66-22.97)] were associated with AGWs. VL [aOR=0.93 (0.93-9.25)] at baseline was not associated with AGWs. Among those with anal swab results, 39% had HPV detectable, 14% with >1 infection; 24% had HR-HPV while 25% had LR-HPV. HPV 6 (8%) was the most commonly detected type; 30% had HPV detected in both anal canal and genitalia with 21% having type concordance. 44% of those with HPV detected had an abnormal anal smear (10% ASCUS and 34% LSIL). 262 anal smears were analysed. 8% were of poor quality, 47% were normal, whilst 18% and 27% were ASCUS and LSIL respectively. There were no HSILs. Infection with ≥ 1 HR types [aOR=1.71 (1.04-2.81)] was associated with abnormal cytology. VL [aOR=0.52 (0.12-2.5)] at baseline was not associated with abnormal cytology.
**Conclusions:** AGWs and cytological abnormalities were prevalent among MLWHA. Infection with ≥ 1 type was associated with disease. Further research is needed to understand incidence, persistence and progression of infection and disease to inform future prevention strategies.

## TUPEC211

### Associations between HPV and HIV among young, gay, bisexual and other men who have sex with men: preliminary findings from the P18 cohort study

F. Kapadia[1,2], D.C. Ompad[1], R.E. Greene[3], P.N. Halkitis[1,2]
*[1]New York University, College of Global Public Health, New York, United States, [2]New York University, Langone School of Medicine, Dept of Population Health, New York, United States, [3]New York University, Langone School of Medicine, New York, United States*
*Presenting author email: farzana.kapadia@nyu.edu*

**Background:** A growing body of literature suggests a relationship between human papillomavirus (HPV) infection and HIV. However, few studies have examined the relationship between site-specific and type-specific HPV infections and HIV among young men who have sex with men (YMSM). Given the high infectivity of HPV as well as its association with anal, penile and oropharyngeal cancer, more information on the relationship between HPV and HIV among YMSM is especially warranted.
**Methods:** Participants were enrolled in the P18 study, a prospective cohort study of health states among young gay, bisexual and other men who have sex with men. Beginning in October 2015, HPV DNA testing via nucleic acid hybridization assay was initiated at the 54-month visit; to date, n=108 YMSM have provided samples for oral HPV and n=99 for anal HPV testing.
**Results:** In this sample of YMSM (mean age=24 years old; 48.2% Hispanic/Latino, 32.4% Black, 9.3% White, 10.2% Asian/Pacific Islander or other race) HIV prevalence was 13.0%. For anal HPV, overall prevalence was 38.2%; by type, prevalence of high-risk strains was 24.5% and 17.3% for low-risk strains. For oral HPV, overall prevalence was 6.4%; by type, prevalence of high-risk strains was 3.6% and 1.8% for low-risk strains. Additionally, 11.8% of this sample tested positive for quadrivalent vaccine preventable strains (6,11,16,18) while 21.6% tested positive for the nonavalent vaccine preventable strains (6,11,16,18,31,33,45,52,58). Finally, the presence of anal HPV (any type) was associated with an HIV seropositive status (OR=5.63, 95% CI=1.44, 21.97; p=0.013) as was the presence of oral HPV (OR=12.13, 95% CI=2.37, 62.12; p=0.003).
**Conclusions:** Our findings provide evidence of high HPV prevalence in YMSM by site (anal/oral) and type (low/high risk strains) as well as for vaccine preventable strains. First, as anal, oral, and oropharyngeal cancers are significant sequellae of HPV infection, further investigation to examine vaccine uptake in YMSM is warranted. Second, the strong associations between HIV and both anal and oral HPV in this new generation of YMSM warrant further investigation to understand how site-specific HPV is associated with increased risk for HIV as well as to understand how HPV persistent is associated with HIV infection.

# Epidemiology of viral hepatitis and HIV co-infection

## TUPEC212

### Development and validation of a risk score to assist testing for acute HCV infection in HIV-infected MSM

A.M. Newsum[1,2], I.G. Stolte[1], J.T.M. van der Meer[2], J. Schinkel[3], M. van der Valk[2], J.W. Vanhommerig[1,3], A. Buvé[4], M. Danta[5], A. Hogewoning[6], M. Prins[1,2], on behalf of the MOSAIC Study Group
*[1]Public Health Service of Amsterdam, Department of Infectious Diseases Research and Prevention, Amsterdam, Netherlands, [2]Academic Medical Center, Department of Internal Medicine, Center for Infection and Immunity Amsterdam (CINIMA), Amsterdam, Netherlands, [3]Academic Medical Center, Department of Medical Microbiology, Amsterdam, Netherlands, [4]Institute of Tropical Medicine, Department of Public Health, Antwerp, Belgium, [5]University of NSW, St Vincent's Clinical School, Sydney, Australia, [6]Public Health Service of Amsterdam, STI Outpatient Clinic, Amsterdam, Netherlands*
*Presenting author email: anewsum@ggd.amsterdam.nl*

**Background:** Current guidelines recommend annual hepatitis C virus (HCV) testing of HIV-infected men who have sex with men (MSM) with ongoing risk behavior, without specifying the type of risk behavior. To improve early detection of HCV, development of clear-cut recommendations is relevant. Therefore, we developed and validated a risk score to assist HCV testing in HIV-infected MSM.
**Methods:** The risk score was developed using data from a Dutch case-control study of HIV-infected MSM with and without an acute HCV infection (MOSAIC study). Self-administered questionnaires on recent sexual behavior were collected and risk factors for HCV were determined using multivariable logistic regression. For each patient an individual risk score was calculated by summing the ß-coefficients of all significant risk factors reported by that patient. Using ROC curves, an optimal cut-off for the risk score to predict acute HCV infection was determined, defined as the

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

highest sensitivity in combination with the highest specificity. The risk score was validated among HIV-infected MSM from case-control studies in Belgium and the UK and from cross-sectional surveys at a Dutch STI-clinic.

**Results:** Receptive unprotected anal intercourse (ß 1.1), sharing of sex toys (ß 1.2), unprotected fisting (ß 0.9), injecting drug use (ß 1.4), sharing straws when snorting drugs (ß 1.0) and ulcerative STI (ß 1.4) were included in the risk score. The optimal cut-off was ≥ 2.0, at which 43% of the study group would be advised to be tested for HCV, with a sensitivity of 78% and a specificity of 79%. In the validation studies sensitivity ranged from 73% to 100% and specificity from 56% to 66% (table).

| | Development study | Validation studies | | |
|---|---|---|---|---|
| | MOSAIC (N = 213) | Belgium (N = 142) | UK (N = 190) | STI-clinic Amsterdam (N = 284) |
| **HCV positive (n)** | 82 | 52 | 60 | 10 |
| **HCV negative (n)** | 131 | 90 | 130 | 274 |
| **Sensitivity** | 78% | 73% | 93% | 100% |
| **Specificity** | 79% | 66% | 56% | 61% |
| **Proportion with a risk score of ≥ 2.0 (% to be tested)** | 43% | 49% | 59% | 42% |
| **Area under the ROC curve (95% CI)** | 0.82 (0.76 - 0.88) | 0.74 (0.66 - 0.83) | 0.82 (0.76 - 0.88) | 0.92 (0.85 - 0.98) |

*[Table. Performance of the HCV risk score among HIV-infected MSM in the development and validation studies]*

**Conclusions:** Our risk score was successful in selecting HIV-infected MSM at risk for acute HCV infection. It could be a promising tool to improve HCV testing strategies for HIV-infected MSM in various settings such as STI-clinics, lowering the number of MSM needed to be tested for HCV and hence test costs.

## EPIDEMIOLOGY OF OTHER DISEASES AND HIV CO-INFECTION

### TUPEC213

### ANXIETY AND MOOD DISORDERS AND HOSPITALISATION IN HIV-INFECTED AND -UNINFECTED GAY AND BISEXUAL MEN

C.L. Moore[1], A.E. Grulich[1], G. Prestage[1,2], H.F. Gidding[3], F. Jin[1], K. Petoumenos[1], I.B. Zablotska[1], I.M. Poynten[1], L. Mao[4], M.G. Law[1], J. Amin[1]
*[1]The Kirby Institute, University of New South Wales, Sydney, Australia, [2]Australian Research Centre in Sex, Health and Society, La Trobe University, Melbourne, Australia, [3]School of Public Health and Community Medicine, University of New South Wales, Sydney, Australia, [4]Centre for Social Research in Health, University of New South Wales, Sydney, Australia*

**Background:** Prevalence of anxiety and mood disorders (AMDs) in HIV-infected individuals have varied widely due to the variety of measurements used for assessment and differences in risk factor profiles between different populations. We aimed to address the question of whether HIV-infection was an independent risk factor for hospitalisation for AMDs in gay and bisexual men (GBM).

**Methods:** HIV-infected (n=557) and -uninfected (n=1325) GBM recruited in Sydney, Australia were probabilistically linked to their hospital admissions and death notifications (2000-2012). Random-effects Poisson models were used to assess risk factors for hospitalisation. Cox regression methods were used to assess risk factors for mortality.

**Results:** We observed 300 hospitalisations for AMDs in 15.3% of HIV-infected and 181 in 5.4% of -uninfected participants. Being infected with HIV was associated with an increased risk of hospitalisation for AMDs in GBM [IRR 2.49 (95%CI 1.47-4.21)]. Other factors which conferred an increased risk included being unemployed [2.41 (1.41-4.12)], identifying as bisexual or 'other' compared with gay, queer or homosexual [5.24 (2.34-11.74)], having a religious belief [2.21 (1.40-3.49)], having previously sought counselling for mental health [4.25 (2.96-8.27)], and being a daily smoker [1.94 (1.22-3.08)]. In the HIV-infected cohort, previous hospitalisation for HIV-related dementia was also associated with hospitalisation for AMDs [IRR 3.08 (95%CI 1.78-5.30)], as was a more recent HIV-diagnosis [linear trend p-value=0.025] and a CD4 T-cell count above 350/mm$^3$ [CD4 cell count 351-500: IRR 0.20 (95%CI 0.07-0.56); 501-750: 0.33 (0.13-0.85); over 750: 0.23 (0.08-0.63)]. Being hospitalised for an AMD was associated with increased risk of mortality [HR 5.48 (95%CI 1.88-8.05)]; this association did not differ by HIV status. Alcohol use was listed as the primary or secondary cause of death for 42.1% HIV-infected and 50.0% -uninfected participants hospitalised for AMDs.

**Conclusions:** Our findings support a higher prevalence of AMDs in HIV-infected compared to -uninfected GBM. There is a need to provide more effective strategies to identify and treat AMDs in HIV-infected GBM and to better understand causes of increased risk in this population at different stages of infection. Our research highlights the importance of further examination of the effects of substance use, neurocognitive decline and AMDs on the health of HIV-infected individuals.

### TUPEC214

### MORTALITY RISK OF NON-AIDS NON-HODGKIN'S LYMPHOMA AMONG HIV-INFECTED HISPANICS ADULTS IN THE COMBINATION ANTIRETROVIRAL THERAPY ERA

A. Mayor[1], E. Santiago[1], E. Rios-Olivares[2], G. Tortolero[3], R.F. Hunter-Mellado[1], D. Fernandez[1]
*[1]Universidad Central del Caribe, Internal Medicine, Bayamon, Puerto Rico, [2]Universidad Central del Caribe, Microbiology, Bayamon, Puerto Rico, [3]University of Puerto Rico, Puerto Rico Central Cancer Regrirstry, San Juan, Puerto Rico*
*Presenting author email: amayorb@hotmail.com*

**Background:** HIV associated immune dysfunction is related to an increased risk for the development of malignant disorders, including the non AIDS defining non-Hodgkin's Lymphomas (NAD-NHL). Multiple spectrum antiretroviral therapy (ART) and its use in combination (cART) have resulted in a dramatic reduction in HIV viremia with improvement in the immunological function and an increment in overall survival. The presence of malignant transformation in HIV infected patients often severely curtails their survival and results in significant morbidity. Our study evaluates the NAD-NHL mortality risks in a Hispanic cohort of HIV infected adults.

**Methods:** The database of HIV infected adults (>20 years) followed in the Retrovirus Research Center at Bayamon, Puerto Rico was matched with the Puerto Rico Central Cancer and Mortality Registries databases. Six and 12 months mortality after NAD-NHL diagnosis were evaluated. Cox proportional hazard analyses including age, sex, smoking, injecting drug use (IDU), CD4 cell count < 200, and cART prescription were used to evaluate the mortality risks.

**Results:** Of the 3,433 HIV adults followed between Jan 1996 and Dec 2013, 31 (0.9%) had a validated NAD-NHL diagnosis. Of them, 67.7% were male, 58.1% smoked, 35.5% were IDUs, 9.7% had one previous AIDS defining condition, 71.0% had a CD4 cells count < 200 and 77.4% received cART previously. The mean age at NAD-NHL diagnosis was 45.6 years and the mean HIV disease duration was of 5.4 years. The 6 and 12 months mortality were 64.5% and 74.2% respectively. Higher 6 and 12 months mortality risk were significantly associated with CD4 cell counts < 200 (HR=4.5; 95% CI: 1.2-16.9 and HR=5.1; 95% CI: 1.25-17.3, respectively) and IDU (HR=3.6; 95% CI: 1.1-12.1 and HR=4.1; 95% CI: 1.2-14.5, respectively). The use of cART was not significantly associated with the mortality risk variation.

**Conclusions:** High NAD-NHL mortality risks in the cART era is suggestive of the role of oncogenic risk factors, inadequate cancer prevention, and inadequate cART adherence that could contribute and accelerate the malignant transformation risk among these vulnerable individuals. Adequate and opportune HIV and NAD-NHL diagnosis and treatment are important to reduce this mortality trend, and are highly recommended.

### TUPEC215

### NON-COMMUNICABLE CHRONIC DISEASES IN HIV-INFECTED PATIENTS IN MALAWI AND THE IMPACT OF ANTIRETROVIRAL THERAPY

S. Mancinelli[1], V. Tamba Tolno[2], M. Giuliano[3], G. Liotta[1], M. Andreotti[3], M. Floridia[3], L. Palombi[1], H. Sangare[2], M.C. Marazzi[4]
*[1]University of Rome, Biomedicine and Prevention Dept, Rome, Italy, [2]DREAM Program, Blantyre, Malawi, [3]ISS, Rome, Italy, [4]LUMSA University, Rome, Italy*
*Presenting author email: drsangarehawa@gmail.com*

**Background:** Background The burden of non-communicable chronic diseases (NCDs) is increasing in sub-Saharan Africa, and is becoming significant cause of morbidity and mortality. More data are needed in the HIV population to inform evidence-based policies addressing these conditions. The objective of this study was to assess the prevalence of hypertension, raised blood glucose, obesity, and renal dysfunction in a population of HIV-positive patients naïve to antiretrovirals and to assess the impact of 6 years of ART on these parameters.

**Methods:** Methods A retrospective analysis was performed of routinely collected data of HIV-positive patients starting antiretroviral treatment in Malawi within the DREAM Program from January 2006 to May 2015. Measurements, including blood pressure, random blood glucose, body mass index (BMI) and estimated Glomerular Filtration Rate (eGFR), were obtained at baseline (before treatment start) and every year for up to 6 years of antiretroviral therapy (ART). Multiple logistic regression models were used to identify factors associated with NCDs and the Cox model was used to assess predictors of survival in the cohort.

**Results:** Results A total of 6297 patients, mean age 37 years, females 57.4%, were studied. At baseline the prevalence of hypertension was 10% (grade II hypertension was 5.2%), diabetes was present in 0.3%, obesity in 1.8%, eGFR < 60 ml/min in 16.9% of the subjects. Increasing age, male sex and higher BMI were correlated to both hypertension and diabetes at baseline. After 6 years of ART the prevalence of hypertension was unchanged, diabetes and obesity slightly increased (1.5% and 3.6% respectively) and the proportion of patients with renal dysfunction strongly decreased (8.9%). Male sex (P=0.017), increasing age (P< 0.001) low baseline BMI (P< 0.001), low baseline hemoglobin (P< 0.001), the presence of diabetes at baseline (P=0.001) were all independent predictors of mortality in the cohort.
**Conclusions:** Conclusions Diabetes and obesity were rare in this HIV-infected population, the prevalence of hypertension was moderate while decreased renal function was common. Antiretroviral therapy had a modest impact on these conditions, with the exception of renal function which significantly improved. These findings are re-assuring in a perspective of general progressive expansion of ART to all HIV-infected people.

## MOLECULAR EPIDEMIOLOGY

### TUPEC216

#### CLINICAL CHARACTERISTICS, TRANSMITTED DRUG RESISTANCE MUTATIONS (TDRM), SUBTYPES AND TREATMENT INITIATION AMONG NEWLY IDENTIFIED INFECTIONS IN SÃO PAULO REFERENCE CENTER, BRAZIL

L.P.O. Coelho[1], L.F. Jamal[2], M.V. Tancredi[2], R.S. Nogueira[2], J.V. Madruga[2], J.O. Gomes[2], L.F.M. Brigido[1]
*[1]Adolfo Lutz Institute, Sao Paulo, Brazil, [2]Reference and Training Center, Sao Paulo, Brazil*
*Presenting author email: luanaportes@yahoo.com.br*

**Background:** Acute and early HIV is a pivotal phase during HIV infection, but in many situations it is still undiagnosed, limiting linkage to care, and antiretroviral therapy initiation, that could both benefit patient and help controlling the epidemic. Our objective was to evaluate clinical and laboratory characteristics of an active effort to recruit newly diagnosed patients in the São Paulo Reference Center.
**Methods:** Consecutive patients with a recent positive HIV test were recruited. At entry, clinical exam, CD4 (flow cytometry, BD), viral load (RT-PCR-Abbott) and HIV genotyping
(RT-PCR followed by nested PCR and big dye, Life) were performed. Sequences were evaluated at Stanford-db (CPR and GRI) and Rega and NCBI was used for genotype.
**Results:** 386 patients were included from November 2013 to December 2015, median age 28 yo (25-34), mostly male( 95.8%), the majority MSM, with a median CD4 514 (25th-75th, 327-666) and viral load of 4.3 (3.8-4.9) at inclusion. A previous seronegative test was reported by 236(61%), with a median time to a positive test of 398 days (197-731). Most common acute infection-like manifestations, observed in 126 cases, were: fever 54%, lymphadenopathy 42%, malaise 41%, myalgia 38% and pharyngitis 34%. Patients were included at a median of 38 days (26-65) after diagnostic. Of 341 sequences evaluated at CPR, TDRM was identified in 11.2 % (NNRTI 6.7%, NRTI 3.9%, PI 1.8%, including 10.3%, with NRTI+NNRTI TDRM). K103N was the most common TDRM. When any resistance mutation was considered, 26.4% of the sequences had at least one mutation to NRTI, NNRTI or a major PI. Subtype B was the most prevalent (74.6%), subtype C 11.3%, F 3.3%, one (0.4%) G and different recombinant forms (10.4%), most BF or BC. The median proportion of nucleotide ambiguities was 0.2% (25th -75th 0 - 0.55); ARV was initiated in 79%. The most commonly used ARV regimens were EFV+3TC+Tenofovir, in 77.7%, and ATZ/r+3TC+TDF, in 12.7% Patient's with DRM received (or changed upon availability of genotype test), a regimen appropriate for the resistance profile.
**Conclusions:** TDR is at intermediate levels but higher than previous studies, with subtype C increasingly been recognized.

### TUPEC217

#### ANALYSIS OF MASSIVELY PARALLEL SEQUENCING OF HIV-1 PROVIRAL GENOMES REVEALS HIGH GENETIC DIVERSITY AMONG BRAZILIAN BLOOD DONORS WITH LONG-STANDING INFECTION

R. Pessôa, S.S. Sanabani
*Instituto de Medicina Tropical - USP, Virology, Sao Paulo, Brazil*
*Presenting author email: rodrigo_pessoa1@hotmail.com*

**Background:** Here, we aimed to gain a comprehensive picture of the HIV-1 diversity in the northeast and southeast part of Brazil. To this end, analysis of massively parallel sequencing "MPS" data were performed to characterize the near full length (NFLG) and partial HIV-1 proviral genomes in 194 HIV-1 infected blood donors with long-standing infection at four major blood centers in Brazil: Pro-Sangue foundation (São Paulo state (SP), n 50), Hemominas foundation (Minas Gerais state (MG), n 28), Hemope foundation (Recife state (PE), n 78) and Hemorio blood bank (Rio de Janeiro (RJ), n 38).
**Methods:** The MPS data covering the NFLG and partial genomes were extracted from our recently generated HIV-1 genomes sequenced by a paired-end protocol (Illumina). Validated *fastq* files from each viral genome were de novo assembled into contiguous sequences and used for further analysis.
**Results:** Of the 194 samples studied, 161 (83%) NFLGs and 33 (17%) partial fragments were *de novo* assembled into contiguous sequences and successfully subtyped. Of these 194 samples, 130 (67%) were pure subtypes consisting of clade B (n = 121, 62.4%), C (n = 6, 3.1%), F1 (n = 2, 1%), and D (n = 1, 0.5%). Recombinant viruses were detected in 64 (33%) samples and consist of unique BF1 (n = 35, 18%), BC (n = 7, 3.6%), BCF1 (n = 4, 2%), CF1 and CDK (n = 1, 0.5%, each), CRF70_BF1 (n = 3, 1.5%), CRF71_BF1 (n = 10, 5.1%), and CRF72_BF1 (n = 3, 1.5%). Evidence of dual infection was detected in four patients coinfected with the same subtype (n = 3) and distinct subtype (n = 1).
**Conclusions:** The overall results revealed a broad array of 12 genetically different HIV-1 variants consisting of four genuine subtypes, three circulating recombinant forms, and five variants with different recombinant profiles. The elevated number of HIV-1 subtypes co-circulating as well as diverse recombinant viruses observed in this work may represents a tangible challenge for future vaccine development, as well as for the efficiency of antiretroviral treatment and diagnostic tests.

#### DIVERSE HIV-1 NON-SUBTYPE B CLUSTERS ARE SPREADING AMONG MEN WHO HAVE SEX WITH MEN IN SPAIN

E. Delgado[1], H. Gil[1,2], M.T. Cuevas[1], A. Fernández-García[1], J. Martínez-López[1], M. Sintes[1], V. Montero[1], M. Sánchez[1], C. Carrera[1], E. García-Bodas[1], S. Benito[1], L. Pérez-Álvarez[1], M.M. Thomson[1], Spanish Group for the Study of new HIV Diagnoses
*[1]Instituto de Salud Carlos III, Majadahonda, Spain, [2]European Program for Public Health Microbiology Training (EUPHEM), European Centre for Disease Prevention and Control, (ECDC), Stockholm, Sweden*
*Presenting author email: mthomson@isciii.es*

**Background:** In Western Europe, HIV-1 subtype B has been largely predominant among men who have sex with men (MSM). However, recently, other clades have been reported in this population, including a large subtype F cluster rapidly expanding in Spain. Here we describe four other non-subtype B clusters spreading among MSM in Spain.
**Methods:** HIV-1 samples from 7780 individuals from seven Spanish regions collected in 1999-2015 were analyzed. A pol fragment was amplified from plasma RNA and sequenced. Phylogenetic analyses were performed via maximum likelihood. Viruses related to identified clusters were searched using BLAST algorithm and phylogenetic analyses. Times of most recent common ancestors (tMRCAs) of clusters were estimated using a Bayesian method.
**Results:** Among identified clusters, there were five large ones of non-subtype B clades associated with recently diagnosed MSM, of subtypes A1 (A1_1, n=29), C (C7, n=15) and F1 (F1_1, n=124; F1_3, n=14), and of CRF02_AG (CRF02_1, n=27). The largest, F1_1, was reported previously. All individuals in these clusters were male, all were infected sexually, and all but two with specified sexual behavior were MSM. None had been diagnosed before 2008. Clusters with greatest recent expansions were A1_1 and F1_3, with most and all cases, respectively, diagnosed in 2014 or 2015. A1_1 comprised viruses from three Spanish regions, Portugal and United Kingdom, and was related to viruses from Southeast Europe. CRF02_1 was found in four Spanish regions, comprised a Japanese subcluster, and was related to viruses from four Western European countries and Ecuador. C7 comprised viruses from two Spanish regions and Portugal. All F1_3 viruses were from the Basque Country, and were related to viruses from Romania. Mean tMRCAs were 1996, 2001, 1988, and 2012 for clusters A1_1, CRF02_1, C7, and F1_3, respectively, and 2010, 2004,

Tuesday 19 July Poster Exhibition
Wednesday 20 July

Friday 22 July
Late Breaker Posters
Author Index

and 2005 for the largest subclusters A1_1_1 (n=17), CRF02_1_1 (n=25), and C7_1 (n=10), respectively.

**Conclusions:** The HIV-1 epidemic among MSM in Spain is becoming increasingly diverse through the recent expansion of non-subtype B clusters, which are related to viruses circulating in other countries. The recent expansion of HIV-1 clusters among MSM makes necessary reinforcing public health measures aimed at preventing high risk sexual behaviors in this population.

## TUPEC219

### ANALYSIS OF HIV-1 SUBTYPE C ENVELOPE SEQUENCE DIVERSITY IN THE FEMALE GENITAL TRACT FROM EARLY INFECTION REVEALS NO EVIDENCE FOR COMPARTMENTALIZATION

B. Mabvakure[1,2], B. Lambson[1,2], K. Ramdayal[3], L. Masson[4], P. Moore[1,2,5], S.A. Karim[5], C. Scheepers[1], C. Williamson[4,5], D. Martin[4], J.-A. Passmore[4,5], G. Harkins[3], L. Morris[1,2,5]
*[1]National Institute for Communicable Diseases, National Health Laboratory Service, HIV Research, Johannesburg, South Africa, [2]University of the Witwatersrand, Faculty of Health Sciences, School of Pathology, Johannesburg, South Africa, [3]University of the Western Cape, South African National Bioinformatics Institute, Cape Town, South Africa, [4]University of Cape Town, Institute of Infectious Diseases and Molecular Medicine, Cape Town, South Africa, [5]Centre for the AIDS Programme of Research in South Africa, Kwa-Zulu-Natal, South Africa*
*Presenting author email: batsiraim@nicd.ac.za*

**Background:** The majority of HIV-1 infections in sub-Saharan Africa are acquired heterosexually through the genital mucosa. A better understanding of the properties of the viruses replicating in the genital tract is important as these viruses are the target of microbicide and vaccine strategies. However, such samples are more difficult to access and viral loads are considerably lower compared to blood.

**Methods:** Plasma and cervicovaginal lavage (CVL) samples were obtained from 18 women enrolled in the CAPRISA Acute Infection study in Durban, South Africa within 2 to 15 weeks of infection and from 3-6 time-points later in infection. HIV-1 RNA was isolated and full length envelope genes were amplified from single genomes by nested PCR and sequenced. Phylogenetic analyses of sequences obtained from each individual were performed using Bayesian Evolutionary Analysis by Sampling Trees (BEAST). The concentrations of 42 cytokines were measured in CVL samples using Luminex Multiplex Flow Cytometric assays.

**Results:** Amplification rates of envelope sequences from acute CVL samples were low (4/18, 22%). Successful amplification was significantly associated with the presence of pro-inflammatory cytokines in the CVL supernatant. From these 4 individuals, a total of 205 plasma and 208 CVL envelope sequences were generated during acute and chronic infection and used to compare evolution in the genital tract and blood. Phylogenetic analysis revealed that all sequences from each individual clustered together and with subtype C reference strains. At all time points CVL and plasma sequences were intermingled on the Bayesian Maximum Clade Credibility trees. Although partial tissue specific clusters were present in each individual, these were largely composed of monophyletic sequences and did not persist. There were no sustained tissue-specific differences in genetic diversity, signature amino acid residues, differential co-receptor usage or the number of PNG sites.

**Conclusions:** In conclusion, although there was some local replication, there was no evidence for the existence of independent viral populations in the genital tract of HIV infected women during early and chronic infection. This suggests that viral populations traffic between the systemic and genital compartments.

# GEOGRAPHICAL INFORMATION SYSTEMS AND HIV

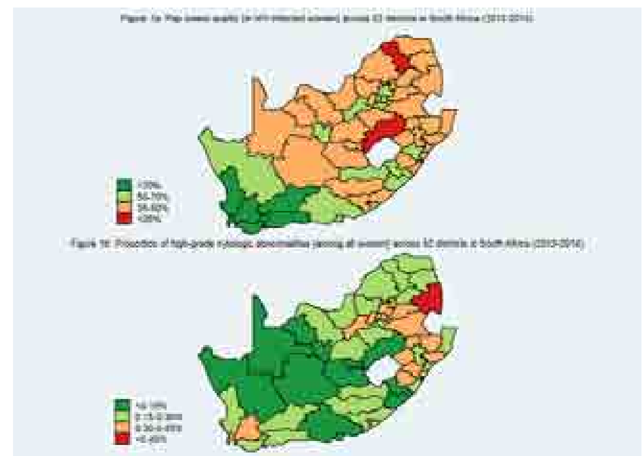
### MAPPING OF PAP SMEAR QUALITY AND RESULTS USING ROUTINELY COLLECTED SOUTH AFRICAN HEALTH FACILITY DATA

C. Makura[1], K. Schnippel[1,2], C. Firnhaber[1,2], P. Michelow[3,4], C.J. Chibwesha[1,5], B. Goeieman[1], S. Jordaan[3,4]
*[1]Right to Care, Johannesburg, South Africa, [2]Clinical HIV Research Unit, University of the Witwatersrand, Department of Clinical Medicine, Faculty of Health Sciences, Johannesburg, South Africa, [3]Cytology Unit, University of the Witwatersrand, Department of Anatomical Pathology, Faculty of Health Sciences, Johannesburg, South Africa, [4]National Health Laboratory Service, Johannesburg,, South Africa, [5]University of North Carolina at Chapel Hill, School of Medicine, Department of Obstetrics and Gynecology, Chapel Hill, United States*
*Presenting author email: caroline.makura@righttocare.org*

**Background:** In South Africa, cervical cancer remains among the most common cancers and a leading cause of cancer death. Co-infection with HIV increases the risk of developing cervical dysplasia and cancer. We analysed National Health Laboratory Service (NHLS) cervical cytology data using choropleth maps to create pictorial representations of Pap smear quality and to investigate geographic variations in Pap smears abnormalities.

**Methods:** Facility-level data were extracted from the NHLS Central Data Warehouse for April 2013 -March 2014. We present results and maps detailing:
(1) Pap smear coverage in HIV infected women defined as the proportion of Pap smears submitted assumed to be from HIV infected women out of population estimate of HIV infected women.
(2) Pap smear quality defined as "adequate" smears in which endo- and ecto-cervical cells are present
(3) High-grade cytologic abnormalities defined as Pap smears suspicious for invasive carcinoma, high-grade squamous intraepithelial lesions (HSIL) or atypical squamous cells: cannot exclude HSIL (ASC-H).

**Results:** From April 2013-March 2014, 4562 facilities submitted 791,067 cytology slides. The interquartile range for Pap smear coverage among HIV infected women was 26-41% which was substantially lower than among HIV uninfected women (32-50%) and overall coverage (44-67%). Overall cytology results are not disaggregated by HIV status. 6/52 districts had adequacy rates above the national standard of 70% and 2/52 districts had adequacy rates below 35%, figure 1a. We observed marked variation in Pap smear abnormalities across the country, with the proportion of high-grade abnormalities >= 0.3% in 17/52 districts figure 1b.



*[Choropleth map showing geographic variations in Pap smear quality and Pap smear abnormalities across South Africa]*

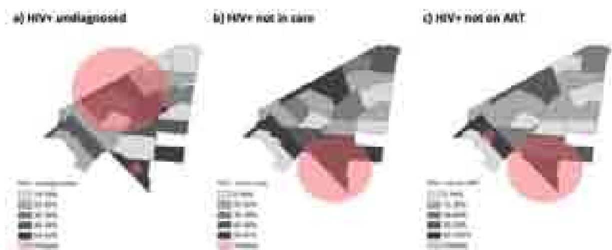
**Conclusions:** Using choropleth maps, we are able to display cervical cancer quality and results. This has important implications for policy, programming and resource allocation, as women with abnormal Pap smears need additional treatment for effective cancer prevention. Urgent interventions are needed to improve coverage and quality or cervical screening, and to address observed regional disparities in results.

## TUPEC221

### SPATIAL DISTRIBUTION OF HIV PREVALENCE AND HIV CARE CASCADE ENGAGEMENT IN AN URBAN INFORMAL SETTLEMENT IN SOUTH AFRICA

A.N. Huber[1], A.E. Aiello[1], S.R. Schwartz[2], C. Hanrahan[2], J.R. Ncayiyana[1,3], N. West[2,4], W.C. Miller[1], M.E. Emch[1], A. Pettifor[1], J. Bassett[4], A. Van Rie[1]
*[1]University of North Carolina at Chapel Hill, Epidemiology, Chapel Hill, United States, [2]Johns Hopkins School of Public Health, Baltimore, United States, [3]School of Public Health, University of the Witwatersrand, Division of Epidemiology and Biostatistics, Johannesburg, South Africa, [4]Witkoppen Health and Welfare Centre, Johannesburg, South Africa*
*Presenting author email: anhuber@live.unc.edu*

**Background:** Spatial analysis of the geography of HIV prevalence and engagement in care has the potential to inform policy and health care delivery. We assessed HIV prevalence and self-reported care status to examine gaps in the treatment cascade and hotspots of HIV infectiousness in an urban South African township.
**Methods:** In 2013-2014, we conducted a cross-sectional randomly selected household community survey of 1231 individuals in Diepsloot, South Africa. HIV prevalence, engagement in HIV care (diagnosed, in care, on treatment), and likelihood of infectiousness (defined as not on treatment or not adherent) were mapped by neighborhood and clusters were identified using Kulldorff's SaTScan™ method (Poisson model, p< 0.05). A log binomial model was used to identify factors associated with HIV infectiousness.
**Results:** Among 1231 individuals enrolled, 195 (16%) were HIV positive. Two-thirds (64%, n=124) self-reported a known positive HIV status, 71 (36%) were newly diagnosed with HIV. Of those known to be HIV positive, two-thirds (68%, n=84) were in care. Based on the 2013 South African ART eligibility guidelines (CD4 count ≤350 cells/µl), 68 of 91 (74%) patients eligible for ART were on treatment. Sixty-seven percent (n=130/195) of HIV positive individuals were classified as infectious. HIV prevalence varied geographically (range 6-24%) and clusters were identified for each step of the care cascade with little geographic overlap between diagnosis and care (Figure). HIV infectiousness was associated with being employed (Risk Ratio=1.34, 95%CI: 0.97-1.86), younger age (18-29 years vs. 30-39 years, RR=1.40, 95%CI: 1.13-1.73), and originating from a country other than South Africa (RR=1.14, 95%CI: 0.93-1.40).



*[Figure 1. Levels of the HIV care cascade by neighborhood in Diepsloot, South Africa 2013-2014]*

**Conclusions:** In a poor urban informal settlement in South Africa, we observed geographical variation in engagement in the HIV care cascade and level of HIV infectiousness, suggesting different drivers for each level of the care cascade. Our findings support the potential for targeted interventions at the neighborhood level.

## TUPEC222

### HIV/AIDS CLINICAL TRIAL ACTIVITY ON THE AFRICAN CONTINENT: AN ANALYSIS OF HIV/AIDS TRIALS REGISTERED ON THE PAN AFRICAN CLINICAL TRIALS REGISTRY (PACTR)

E. Pienaar[1], T. Kredo[2]
*[1]South African Medical Research Council, Cochrane South African, Tygerberg, South Africa, [2]South African Medical Research Council, Cochrane South Africa, Cape Town, South Africa*
*Presenting author email: elizabeth.pienaar@mrc.ac.za*

**Background:** HIV/AIDS is a major public health problem which poses a significant threat to livelihoods and social security in resource-poor countries due to rapid spread of infection amongst individuals at the prime of their productive age. Sub-Saharan Africa is most affected with an estimated 24.7 million people living with HIV in 2014, and accounts for almost 70% of new infections globally.
The Pan African Clinical Trials Registry (www.pactr.org) is the only World Health Organization endorsed primary registry in Africa and aims to improve research transparency and reduce publication bias. This study describes the current status of HIV clinical trials registered on PACTR.
**Methods:** We conducted a cross-sectional analysis of HIV/AIDS trials registered on PACTR. Data extraction included trial location, intervention studied, principle investigator location, participant age range, and funder. Descriptive analysis was run in MS Excel™.
**Results:** 623 trials were registered on PACTR from 1 May 2007 - 03 February 2016. Eighty trials (13%) report planned or ongoing research on HIV/AIDS interventions. Twenty-nine (29/80) trials evaluate treatment. Twenty-two trials evaluate prevention, of these nine investigate vaccines, five behavioural prevention interventions, three diagnostics, four PMTCT and one early infant circumcision. Sample sizes range from 15 to 15 160 participants. Twenty trials include children, one includes participants aged 35 to 49 days.
Forty-nine trials are single-centred and conducted in South Africa, Uganda,Tanzania, Zimbabwe, Malawi, Nigeria, Kenya, Cameroon, The Gambia, Guinea Bissua, Ethiopia, Nigeria, Ghana, Zambia and Mozambique. Thirty-one multi-centre trials are conducted in South Africa, Ethiopia, Tanzania, Guinea Bissau, Gabon, Benin, Kenya, Mozambique, Nigeria, Zambia, Uganda, Senegal, Zimbabwe, Cote D'Ivoire, and Cameroon.
Fifty-seven principal investigators are from African counties with remaining 23 from Europe, United Kingdom, U.S.A. Twenty-four (30%) trials are funded partially or entirely by European and Developing Countries Clinical Trials Partnership (EDCTP). Five trials are funded by pharmaceutical companies.
**Conclusions:** Thirteen percent of trials in PACTR include planned or ongoing HIV/AIDS interventions, predominantly focused on HIV treatment. Increasingly, principal investigators are based in Africa. As registrations increase, PACTR may be used as a tool for mapping changing HIV/AIDS trial landscape. PACTR provides information on African trials to WHO's International Clinical Trials Registry.

## TUPEC223

### SPATIAL ANALYSIS OF HIV INFECTIONS IN HIGH BURDEN SUB-DISTRICTS IN KWAZULU-NATAL, SOUTH AFRICA

U.E. Buthelezi[1], A. Kharsany[2], C. Cawood[3], D. Khanyile[3], A. Grobler[4], L. Madurai[5], T. de Oliveira[6], S. Ntuli[7], F. Tanser[8,9]
*[1]Centre for Aids Programme of Research in South Africa (CAPRISA), University of KwaZulu Natal, Medical Microbiology, Durban, South Africa, [2]Centre for the AIDS Programme of Research in South Africa (CAPRISA), University of KwaZulu-Natal, Medical Microbiology, Durban, South Africa, [3]Epicentre AIDS Risk Management (Pty) Limited, Epicentre, Cape Town, South Africa, [4]Centre for the AIDS Programme of Research in South Africa (CAPRISA), University of KwaZulu-Natal, Statistics, Durban, South Africa, [5]Global Clinical and Virology Laboratory, Clinical Virology, Amanzimtoti, South Africa, [6]Africa Centre for Population Health, University of KwaZulu-Natal, School of Public Health, Durban, South Africa, [7]Africa Centre for Population Health, Geographic Information Systems, Mtubatuba, South Africa, [8]Africa Centre for Population Health, University of KwaZulu Natal, Mtubatuba, South Africa, [9]University of KwaZulu Natal, School of Nursing and Public Health, Durban, South Africa*
*Presenting author email: sah.buthelezi@caprisa.org*

**Background:** The HIV epidemic is heterogeneous within different regions of sub-Saharan Africa, with South Africa having one of the fastest growing HIV epidemics in the world. HIV heterogeneity exists not only between countries but also across national and provincial levels as well as at district and sub-district levels. To better understand the geographical heterogeneity of HIV infections for targeted interventions, we applied spatial analytical methods on the data obtained from the HIV Incidence Provincial Surveillance System (HIPSS), a household-based survey designed to monitor HIV prevalence and incidence in rural KwaZulu-Natal.
**Methods:** HIPSS enrolled 9812 individuals aged 15-49 years from randomly selected households in 2014-2015. Each individual was geo-located using Global Positioning Systems (GPS) to record the geographic co-ordinates of the household. HIV prevalence was calculated per municipal ward to create a thematic map using MapInfo Pro™ version 15.2 GIS software. Micro-geographical cluster detection of clusters of infections was performed using a Kulldorff spatial scan statistic (Bernoulli model) set with a maximum cluster detection radius of 3 km and a significance level of p< 0.05.
**Results:** Kulldorff clusters were superimposed on the generated HIV prevalence map. Overall HIV prevalence was 36.3% (95%CI 34.8-37.8) and prevalence by municipal ward ranged from 30.1% (95% CI: 27.1-33.2) to 50.1% (95% CI: 44.9-55.4). At a micro-geographical level, one high-risk cluster was identified in the North West of the study area by the Kulldorff spatial scan statistic where HIV prevalence exceeded 70% (relative-risk =1.75; p=0.017). This cluster was located in a semi-rural community with only one health care facility being relatively in close proximity.
**Conclusions:** Our findings confirm the extremely high burden and variability of HIV infections across the study area. The presence of a localised high-risk community at this stage of the epidemic suggests that this community may play a key role in sustaining the epidemic within this region and thus should be the focus of a geographically targeted intervention. Further work is ongoing in the high-risk community identified in this survey.

# STUDIES OF RISK BEHAVIOURS AND THEIR IMPLICATIONS FOR PREVENTION

## TUPEC224

### TRANSACTIONAL SEX, HOUSING INSTABILITY, AND SAFER SEX MOTIVATION DETERMINE SEXUAL RISK AMONG RECENT AFRICAN GAY AND BISEXUAL IMMIGRANTS TO NEW YORK CITY

T. Sandfort, C. Anyamele, C. Dolezal
*Columbia University, Psychiatry, New York, United States*
*Presenting author email: tgs2001@cumc.columbia.edu*

**Background:** To understand HIV risk in gay and bisexual men who migrated from countries where homosexuality is illegal and suppressed, to places with increased tolerance and opportunities for sexual expression.

**Methods:** We conducted structured face-to face interviews with 70 sexually active gay and bisexual men who had migrated within the past 5 years from Western and Eastern African countries to New York City (NYC). Sexual risk was assessed as an index based on number of times and number of men with whom one had condomless receptive and/or insertive anal sex (range 0 to 4). Housing instability was assessed with a 5-item scale (α=.72). Eight men who reported being HIV positive were excluded from the analyses.

**Results:** The 62 men who were HIV negative or did not know their status (mean age 31 years) came from 15 different African countries. Sexual repression was the most common reason for leaving one's home country. Over a third of the men reported always having used condoms in the past year; among the other men, sexual risk varied. Current engagement in transactional sex and motivation to avoid HIV infection were identified as independent predictors of sexual risk in a forward stepwise regression analysis that also included HIV knowledge, attitudes towards condoms, alcohol and drug use, social support, internalized homophobia, mental distress, PTSD, stability of immigration status, migratory grief, and housing instability ($R^2$=.35). Examination of bivariate relationships suggests that motivation to avoid HIV infection is undermined by housing instability, whereas housing instability also seems to promote engagement in transactional sex. Housing instability was furthermore associated with an unstable migration status (being undocumented or seeking asylum), less social support, having to borrow money from friends, and more alcohol and drug use. Men for whom migration had been difficult, who had been less open about their homosexuality in their home country, and who had forced sex experiences before coming to NYC, also reported more housing instability.

**Conclusions:** To prevent HIV transmission among African gay and bisexual immigrants it is critical to address the disempowerment caused by the migration experience, particularly as it concerns housing and social position more generally.

## TUPEC225

### TRANSACTIONAL SEX AND ITS ASSOCIATED FACTORS AMONG WOMEN ATTENDING ANTIRETROVIRAL CLINICS IN OGUN STATE, NIGERIA

V.J. Animasahun[1], O.O. Sholeye[2], B.K. Oyewole[1]
*[1]Lagos State University Teaching Hospital, Lagos, Nigeria, [2]Olabisi Onabanjo University Teaching Hospital, Community Medicine and Primary Care, Sagamu, Nigeria*
*Presenting author email: folasholeye@yahoo.com*

**Background:** Despite global advancement in HIV research and control, HIV prevalence and transmission is still of public health concern in low resource climes like Nigeria. Transactional sex has been shown to be associated with HIV risk behaviours and increased transmission. This study therefore assessed the prevalence of transactional sex and its associated factors among women attending antiretroviral clinics in Ogun State, Nigeria.

**Methods:** A cross-sectional descriptive study was carried out 204 women attending antiretroviral clinics in two public tertiary health facilities in Ogun State, Nigeria via systematic random sampling. Data was collected using a validated, semi-structured, interviewer-administered questionnaire and was analysed using IBM SPSS 17.0. Relevant descriptive and inferential statistics were calculated with level of significance set at $p < 0.05$. Respondents' informed consent was obtained and strict confidentiality was ensured. Participation was fully voluntary.

**Results:** The mean age of respondents was 38.3±9.0 with the modal age group being 31-40 years. Two-thirds (66%) were in a monogamous marriage and majority (76%) were Christians. About two-thirds (64.2%) had at least secondary education. About one-third (36.3%) lived in a room apartment. Almost half (42.9%) spent over 50% of their monthly income on food. Majority (87.7%) were not on any food assistance program and over four-fifths (85.8%) have commenced antiretroviral therapy. Prevalence of transactional sex was 7.4%. Household size (p=0.031), marital status (p=0.015), reduction of food ration unwillingly (p=0.010), skipping of medications due to lack of food (p=0.001) and starving for a whole day (p=0.044) were significantly associated with transactional sex. Transactional sex had no significant association with age (p=0.473), educational status (p=0.498), family type (p=0.877), occupation (p=0.312), housing type (p=0.249), percentage of income spent on feeding (p=0.923), being on food assistance program (p=0.351) and commencement of antiretroviral drugs (p=0.154).

**Conclusions:** The prevalence of transactional sex was high. Feeding concerns and skipping of medications were significantly associated with transactional sex. Food assistance programs, socioeconomic empowerment schemes and targeted counselling should be given to people living positively with HIV to halt and reverse HIV transmission.

## TUPEC226

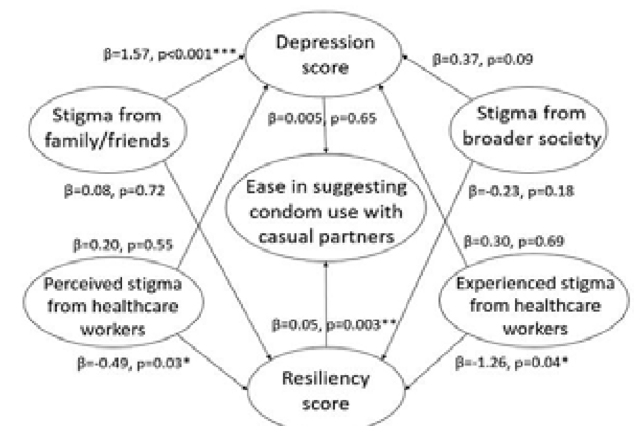
### STIGMA, RESILIENCY, AND CONDOM NEGOTIATION WITH CASUAL SEXUAL PARTNERS AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN SENEGAL

S. Stahlman[1], D. Diouf[2], F. Drame[2], S. Ketende[1], C. Lyons[1], B. Liestman[1], K. Coly[3], D. Castor[4], S. Baral[1]
*[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Enda Santé, Dakar, Senegal, [3]Hôpital Le Dantec, Laboratoire de Bactériologie-Virologie, Dakar, Senegal, [4]USAID, Office of HIV / AIDS, Bureau for Global Health, Arlington, United States*
*Presenting author email: kcoly1@jhu.edu*

**Background:** Sexual behavior stigma is associated with increased risk for HIV infection and suboptimal HIV treatment outcomes among MSM particularly in low-and middle-income countries, although data on causal pathways of stigma are limited.

**Methods:** We collected data on 718 MSM aged >18 years across three cities in Senegal via respondent-driven-sampling. Participants were asked to report lifetime experiences of sexual behavior stigma as a result of having sex with men. In addition, participants were screened for depression (PHQ9), resilient coping ability (Brief Resilient Coping Scale), and were asked in general how difficult or easy it was to suggest the use of condoms with casual male sex partners. Structural equation modeling (SEM) was used to estimate indirect effects of stigma on perceived difficulty in suggesting condom use among MSM who had never been told they are living with HIV.

**Results:** 340 MSM reported any casual partners and were included in the final SEM. An asymptotic distribution free estimation method was used due to lack of joint normality of the endogenous variables. For each pathway modeled in the SEM, we adjusted for age and employment status. Perceived and experienced sexual behavior stigma from healthcare workers was significantly associated with reduced resilient coping ability (Figure 1). In contrast, higher resilient coping ability was associated with improved condom negotiation with casual male sex partners. Stigma from family/friends was associated with increased depression although not found to be associated with resiliency. Finally, there was no direct relationship between depression and condom negotiation.



*[Figure 1. SEM showing adjusted relationships between stigma, depression, resiliency, and ability to suggest condom use with casual male sex partners, among MSM in Senegal (N=340). ***p<0.001, **p<0.01, *p<0.05]*

**Conclusions:** In the context of novel HIV intervention approaches such as pre-exposure prophylaxis and universal treatment, consistent condom use with casual sexual partners remains crucial for the prevention of HIV acquisition and transmission. These results suggest that stigma and mental health represent important determinants of risk among MSM, and thus should represent targets of comprehensive intervention strategies.

## TUPEC227

### FACTORS ASSOCIATED WITH UNPROTECTED ANAL INTERCOURSE IN MEN WHO HAVE SEX WITH MEN (MSM): FINDINGS FROM THE FIRST BIO-BEHAVIORAL SURVEY USING RESPONDENT-DRIVEN SAMPLING AMONG MSM IN BAMAKO, MALI

P. Patnaik[1], A. Hakim[2], A. N'Dir[3], N. Telly[4], J. Knox[5], T. Ballo[6], B. Traore[6], S. Doumbia[4], M. Lahuerta[5]
*[1]ICAP-Columbia University, Mailman School of Public Health, New York, United States, [2]Centers for Disease Control and Prevention, Atlanta, United States, [3]Centers for Disease Control and Prevention, Bamako, Mali, [4]University of Bamako, International Center for Excellence in Research, Bamako, Mali, [5]ICAP-Columbia University, Epidemiology, New York, United States, [6]Mali Ministry of Health, Cellule Sectorielle de Lutte Contre le SIDA, Bamako, Mali*
*Presenting author email: pp2475@columbia.edu*

**Background:** HIV prevalence among men who have sex with men (MSM) in Bamako, Mali is 13.7%, 8-9 times that among men overall. A contextual understanding of unprotected anal intercourse (UAI) is needed to inform HIV prevention programs. We analyzed data from a recent survey of MSM to identify factors associated with UAI.
**Methods:** We conducted a cross-sectional survey of 552 MSM using respondent-driven sampling between October 2014 and February 2015. Eligibility criteria included being ≥18 years old, residence in Bamako or its suburbs in the preceding 6 months, and having had sex with another man in the preceding 6 months. Participants underwent a face-to-face interview before being counseled and tested for HIV. Weighted data analysis was conducted with RDSAT and SAS to generate population based results. Survey logistic procedures were used to identify factors associated with UAI in multivariate analyses, controlling for age and education.
**Results:** Most (54.3%, 95%CI 48.1, 60.6) MSM were 20-24 years old; 47.3% (95%CI 41.1, 53.6)had a secondary education and 91.8 (95%CI 88.5, 95.1) were never married. Nearly all MSM were Malian (94.5%, 95%CI 91.0, 98.0) and Muslim (88.3, 95%CI 84.0, 92.6). As for relevant knowledge and behaviors: 30.8% (95%CI 25.3, 36.3) had ≥3 male partners in the preceding 6 months; 44.0% (95%CI 37.5, 50.5) listed UAI as the riskiest type of sex; 57.1% (95%CI 50.9, 63.6) identified condom use during anal intercourse as more important than during vaginal intercourse; and 40.7% (95%CI 34.5, 46.8) of men reported UAI with their most recent partner. Factors independently associated with UAI in the preceding 6 months included: inability to access condoms (aOR 4.5, 95%CI: 2.3-9.0); number of male partners in preceding 6 months (aOR 3.9, 95%CI 1.9-8.0 for 2 vs. 1; aOR 2.6, 95%CI 1.3-5.1 for ≥3 vs. 1); knowing HIV-positive MSM (aOR 3.1, 95%CI:1.3-7.1); and age of first male partner (aOR 5.5, 95%CI 1.4-20.9 for < 14 vs. 15-24 years).
**Conclusions:** HIV prevention programs for MSM in Bamako should target UAI reduction among MSM by increasing condom access, reinforcing importance of reducing number of male sex partners, and encouraging limitation of anal intercourse when condoms are unavailable.

## TUPEC228

### SEX TOURISM AMONG CHINESE MEN WHO HAVE SEX WITH MEN: IMPLICATIONS FOR HIV PREVENTION

J. Mao[1,2], W. Tang[1], C. Liu[1], N.S. Wong[1,3], S. Tang[1], Y. Qin[4], C. Wei[5], J.D. Tucker[1]
*[1]University of North Carolina, Project China, Guangzhou, China, [2]University of California, David Geffen School of Medicine, Los Angeles, United States, [3]University of North Carolina at Chapel Hill, Chapel Hill, United States, [4]UNC Project China, Guangzhou, China, [5]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States*
*Presenting author email: yxq59@case.edu*

**Background:** Sex tourism among men who have sex with men (MSM) provides a potential risk for spread of HIV and other STIs. Our objective was to characterize the frequency, socio-demographic characteristics, and sexual risk behaviors among Chinese MSM sex tourists.
**Methods:** An online, cross-sectional survey for MSM throughout China was conducted in November 2015. Questions covered sociodemographic characteristics and sexual risk behaviors. Sex tourism was defined as traveling outside of one's hometown and purchasing sex with gifts or money. Univariate and multivariate logistic regressions were performed to identify correlates of sex tourism. Using participant-reported sex tourism destinations, we compared the reported mean MSM HIV prevalence between their journey origins and destinations.
**Results:** In total, 1192 MSM completed the survey, with 62 (5.2%) identifying as sex tourists, and 20 (32.3%) traveling for the primary purpose of purchasing sex. Of the sex tourists, 53 (85.5%) were educated beyond high school, 19 (30.6%) reported more than three sex partners in the last three months and 23 (37.1%) reported condomless sex in the last month. In multivariate analyses, sex tourists were more likely to have high risk sexual behaviors such as sex while drunk (odds ratio (OR) 4.67, 95%CI 2.64-8.27), receiving payment for sex (OR 3.18, 95%CI 1.68-6.02), more than 6 sex partners in the last three months (OR 2.95, 95%CI 1.14-7.52), group sex (OR 2.81, 95%CI 1.44-5.51), and condomless sex in the last month (OR 1.86 95%CI 1.06-3.25). Sex tourists were more likely to report HIV testing (OR 1.50 95%CI 1.13-3.41) and a positive HIV result (OR 2.21 95%CI 0.82-5.98) in univariate analyses. Sex tourism travel was more often from locations with a lower MSM HIV prevalence (M=4.47, SD=2.01) to locations with a higher MSM HIV prevalence (M=6.86, SD=5.24); t(91)=-4.218, p< 0.001.
**Conclusions:** MSM sex tourists were more likely to participate in risky sexual behaviors and travel to locations with a higher HIV prevalence. Phylogenetic research would be useful to examine how sexual mixing among sex tourists influences onward HIV transmission. Programs that reach and retain high-risk, mobile groups of MSM such as sex tourists should be considered.

## TUPEC229

### CHARACTERISTICS OF HIV RISKS AMONG THAI YOUNG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER YOUTH USING AN ECOUNSELING PLATFORM

T. Anand[1,2], C. Nitpolprasert[1,2], J. Ananworanich[2,3,4], J. Jantarapakde[1], S.J. Kerr[5], A.H. Sohn[6], K.E. Muessig[7], L.B. Hightow-Weidman[8], P. Phanuphak[1,5], N. Phanuphak[1,2]
*[1]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, [3]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [4]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [5]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [6]TREAT Asia/amfAR, The Foundation for AIDS Research, Bangkok, Thailand, [7]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Department of Health Behavior, Chapel Hill, United States, [8]Behavior and Technology Lab, Institute for Global Health and Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, United States*
*Presenting author email: tarandeepsinghanand@gmail.com*

**Background:** Many young men who have sex with men (YMSM) and TG youth in Thailand are closeted, experience societal stigma and are not provided education on safe sex practices from their families or in schools, relying instead on the Internet or friends for basic information. We evaluated risk behaviors and characteristics of Thai YMSM and TG youth seeking sexual health advice and online HIV counseling.
**Methods:** Adam's Love (www.adamslove.org), an innovative HIV prevention intervention launched by The Thai Red Cross AIDS Research Centre (TRCARC) has established a sustainable e-counseling platform for Thai MSM and TG, to provide linkage to HIV testing and treatment services. Those counseled are encouraged to complete risk behavior surveys.
**Results:** Between Sep 2011 - Dec 2015, 17,357 MSM and TG received online counseling. Of 547 MSM and TG who received online counseling and completed a behavioral risk survey in the last quarter of 2015, 72% were age ≤25 years and almost half sought sex using social media (41.5%). Participants aged 14-18 years were less likely to use condoms with casual partners (50%) vs. those aged 19-25 years (33%) and aged ≥26 years (29%); P=0.004). Most had never been tested for HIV (79% vs. 51% for MSM aged 19-26 and 35% for those aged ≥26 years; P< 0.001). Seven percent of all participants reported illicit drug use in the previous 6 months, and rates were similar across age groups. In a multivariate logistic regression model, finding sex partners through social media (aOR 2.0, 95%CI 1.4-2.8; P< 0.001), using illicit drugs (aOR 2.1, 95%CI 1.1-4.1; P=0.03) and younger age was associated with inconsistent condom use with casual partners. Compared to participants aged ≥26 years, those aged 14-18 years had significantly higher odds of inconsistent condom use (aOR 2.8, 95%CI 1.6-4.9; P=0.001); in those aged 19-25 years the odds was comparable (aOR 1.3, 95%CI 0.8-1.9; P=0.3).
**Conclusions:** In this study, the youngest group of MSM and TG assessed engaged in the highest risk behaviors and had lower rates of testing. This highlights the need for continued investment in online interventions, such as e-counseling to provide linkage to HIV testing and treatment services.

## TUPEC230

### NETWORKS OF RECENTLY-INFECTED PEOPLE WHO INJECT DRUGS (PWID) IN ATHENS, GREECE, JUNE 2013 - JULY 2015: EPIDEMIOLOGICAL INSIGHT FROM A PROJECT TO REDUCE HIV TRANSMISSION

S.R. Friedman[1], L.D. Williams[1], E. Pavlatina[2], D. Paraskevis[3], J. Schneider[4], B. Skaathun[5], E. Morgan[6], A. Hatzakis[3], M. Psichogyiou[7], E.-G. Kostaki[8], G. Nikolopoulos[2,9], Transmission Reduction Intervention Project Collaboration Group
*[1]National Development and Research Institutes, Institute for Infectious Disease Research, New York, United States, [2]National Development & Research Institutes, Inc, Athens, Greece, [3]University of Athens Medical School, National Retrovirus Reference Center, Department of Hygiene, Epidemiology and Medical Statistics, Athens, Greece, [4]University of Chicago, Department of Medicine and Department of Health Studies, Chicago, United States, [5]University of Chicago Medical Center, Center for AIDS Elimination, Chicago, United States, [6]University of Chicago, Department of Public Health Sciences, Chicago, United States, [7]Laikon General Hospital, First Department of Internal Medicine, Athens, Greece, [8]University of Athens Medical School, Athens, Greece, [9]Hellenic Centre for Disease Control and Prevention, Athens, Greece*
*Presenting author email: friedman@ndri.org*

**Background:** Following HIV acquisition, high viral loads and risky networks can interact to generate epidemic outbreaks if the newly-infected engage in risk behaviors with networks that include large numbers of **uninfected** partners. We describe 46 recently-infected PWID's injection and sexual networks.
**Methods:** HIV seropositive PWID were recruited and classified as recently-infected seeds using an algorithm incorporating data on HIV status, testing history and Limiting Antigen Avidity ODn. We recruited seeds' (last-6-month) injection and sexual network members, including people who attend injection sites or sex venues they use. Network members were assessed for recent and acute infection. All participants were interviewed about risk behaviors and numbers of partners.
**Results:** We recruited 45 recently-infected PWID (36 men; 9 women). They generated 66 network members whom we tested and interviewed, of whom 43 were uninfected (35 of these were PWID). On average, each *uninfected network member* reported sex with 2.4 partners in the last 6 months, for a total of 104 partners. These data seriously **underestimate** the numbers of HIV-negatives in their networks. This is shown by the fact that we could recruit only 66 members of the 45 recently-infected participants' networks but these 45 recently-infected participants reported injecting with 219 PWID and having sex with 340 partners. If their partners were 65% uninfected (the rate among the recruited network members), and accounting for overlap between injection and sex networks, this suggests that the 45 recently-infected participants had at least 200 uninfected people in their immediate networks—and these 200 people had the potential of infecting many more while their viral lads were high if they became infected. Reports on network members' risk behaviors indicate that men had condomless sex with 43% of their partners, women with 23% of their sex partners, and that 44% of PWID in the networks passed used syringes on to others.
**Conclusions:** Recently-infected PWID engage in risk behaviors with large numbers of HIV-negative sex and injection partners, and these also have large numbers of negative partners. This poses risk of explosive HIV outbreaks. Interventions to locate Recents and reduce their transmission potential are sorely needed.

## TUPEC231

### THE UNREACHED POPULATION IN HIV PREVENTION: FEMALE SEX PARTNERS OF CURRENTLY MARRIED MEN HAVING SEX WITH MEN IN THANE, MAHARASHTRA, INDIA

S.P. Sakthivel[1], A. Yadav[1], T. Shaik[1], R. Khambampati[1], A. Agarwal[1], S. Kaul[2]
*[1]Public Health Foundation of India, PIPPSE, Haryana, India, [2]USAID, Delhi, India*
*Presenting author email: saravanamurthy.ps@phfi.org*

**Background:** In India, Men having Sex with Men (MSM) is one of the key population for HIV prevention programme; but the programme has been facing challenges due to homosexuality being penalized and not socially accepted. Due to this status, the MSM population is hiding themselves and living a dual life. This analysis, is to study and understand whether the currently married MSM in Thane are sharing about their homosexual behavior with their female partners.
**Methods:** Behavioral Tracking Survey was conducted in 2015 among 458 MSM through probability-based two stage sampling. Descriptive analysis on age, age of first sex, age of first vaginal sex, the first female sex partner, current status on having a female sex partner and condom usage in the last one year. Bivariate analysis along with chi-square statistics has been conducted for significance between marital status aforementioned variables.
**Results:** The mean age of currently married MSM (N=148) and never married MSM (N=302) is 32.6 years and 25.1 years respectively. The mean age of first vaginal intercourse is much later among currently married MSM (21.8 years) than never married MSM (17.7 years). Among the currently married, the self-identity is distributed with 21.6% kothi, 27.7% panthi, 23% double-decker and 27.7% bisexual, Whereas among never married MSM, it is predominantly kothi identity (58.6%), followed by 19.2% double-decker, 13.6% panthi and 8.6% bi-sexual. Among 45% of the currently married MSM presently living with a female sex partner, 52% (35/67) had reported of not using condom during the last sexual encounter. Highly significant proportion of currently married MSM had reported of ever had vaginal intercourse (P< 0.001) against never married MSM. The never married MSM are increasingly sharing about their male sexual partners, to their female sex partners, rather than the currently married MSM (P< 0.1).
**Conclusions:** The findings shows, the currently married MSM are hiding their homosexual behaviour with their female counterparts and 50% have practiced unsafe sex in last sexual encounter, thereby increasing the chances of HIV transmission. Hence HIV programme among MSM particularly in India, needs to find a strategy on reaching out to the female sex partners of MSM.

## TUPEC232

### COMMUNITY MEMBERSHIP, FINANCIAL SECURITY, SOCIAL PROTECTION AND HIV RISK BEHAVIORS AMONG MSM IN INDIA: FINDINGS FROM AVAHAN-III EVALUATION STUDY

R. Adhikary, S.K. Patel, M. Battala
*Population Council, New Delhi, India*
*Presenting author email: radhikary@popcouncil.org*

**Background:** Community membership, financial security and social protection are crucial to confront HIV risk among high risk population in developing countries. This study assesses community membership, financial security and social protection among Men who have Sex with Men (MSM), and explores its association with their HIV risk behaviors in India.
**Methods:** Data were drawn from the Avahan-III baseline evaluation survey- 2015, conducted among MSM (n=1005) in three states of India. Two stage cluster sampling approach was used to select the required number of MSM for the survey. Adjusted odds ratios (AOR) and their 95% confidence intervals (CI), bivariate analysis and frequency were used to assess the relationships between community membership, financial security and social protection with HIV risk behaviors.
**Results:** Most of the MSM were a registered member of any community organizations (88%) and having any social entitlements (Ration/BPL card, Aadhar card and Voter ID) (89%), whereas more than 73% had functional savings account either in a nationalized bank or post office, and 21% reported access to any social protection schemes. MSM, those who were member of a CO (21% vs. 3%; AOR: 8.7), had access to any social entitlements (20% vs. 11%; AOR: 2.1) and had a functional savings account (22% vs. 12%; AOR: 1.7) were significantly at higher chances of using condom consistently with both paying as well as paid male partners than others. The odds of consistent condom use with non-paying non-regular and non-paying regular male partners are also higher among MSM those had access to any social protection schemes, having a functional saving account compared to their counter parts.
**Conclusions:** Findings from the study show that there is significant association between community membership, financial security and social protection with consistent condom use with different type of sex partners among MSM. The maintenance of high levels consistent condom use is central to improve the usefulness and sustainability of HIV prevention programs. However, more community outreach activities, research and advocacy are required to highlight these issues in a wider context.

## TUPEC233

### ASSESSING SEXUAL RISK BEHAVIOR IN THE YOUNGER AND OLDER MALE DRIVERS IN IBADAN, NIGERIA

T. Lawoyin, O. Lawoyin
*Frontline Research & Training in Reproductive & Family Health, Columbia, United States*
*Presenting author email: toolawoyin@yahoo.com*

**Background:** Long distance drivers like most mobile workers are at greater risk for acquiring and spreading sexually transmitted infection including HIV/AIDS. This community-based comparative study examined sexual risk behavior among long distance commercial drivers of different ages to identify their prevailing risky behavior.
**Methods:** Using multistage sampling technique, commercial drivers from six randomly selected motor parks in Ibadan, Nigeria were interviewed using a standardized questionnaire.
**Results:** There were 112 [37.5%] men ≤40years and 186 [62.2%] >40 years. The older men had spent more years driving [mean 24.1 vs 12.8 yrs, p< 0.0001] and the religious profile were similar. More younger men 57[50.9%] than older men

67[36.4%] $X^2$ =5.993, p=0.014 had completed secondary school and /or had higher education. The older men were more likely to be married [98.4% vs 91.1%, p=0.02], to be polygamous [36.8 vs 13.6%, p< 0.0001] and to have more wives [p=0.0001]. The younger men were more likely to have regular girlfriends [61.6% vs 50.5%, $X^2$ =3.46,p=0.06]. Mean age at sexual debut was significantly lower in the younger men [18.2 ±3.9 vs 22.1 ±11.2 yrs, p=0.0004]; A similar proportion of men in both groups had ever paid to have sex but the younger men were more likely to have had sex with a commercial sex worker [CSW] within last 12 months prior to this study [9.6% vs 2.3%,p=0.0075]. Younger men were more likely to report ever using condom [73.2 vs 56.5%, p=0.039]; the younger men were also likely to always negotiate condom with CSW [80 vs 44.4%]. There was no difference in the proportion that reported ever having an STI [p>0.05]; there was no difference in their mean attitude scores for HIV/AIDs , & the younger men had higher mean knowledge scores than their counterpart [p=0.08]. HIV testing was similar [26.8 vs 29.6% ,P>0.05]. Multivariate analysis showed that polygamy [OR=3.9 (1.9-7.9),p=0.000]; never use of condoms [OR=2.3 91.25-4.3),p=0.008]; and patronizing CSW [OR=5.0, (1.1-22.0) p=0.032] increased their risks. This however only explained 14.8% in the variance due to risky behavior.
**Conclusions:** Age has an impact on men's behavior. Preventive messages that will attract the attention of men of different ages must be embraced.

## TUPEC234

### Factors associated with inconsistent condom use by female sex workers with their non-paying partners in Johannesburg, Cape Town and Durban

M. Sibanyoni[1], N. Mutanha[1], T. Osmand[2], A. Marr[2], F. Venter[1], H. Rees[1], T. Lane[2]
[1]*Wits Reproductive Health and HIV Institute (WRHI), Johannesburg, South Africa,* [2]*University of California, San Francisco, Center for AIDS Prevention Studies/Medicine, San Francisco, United States*

**Background:** The South African National Strategic Plan recognizes female sex workers (FSW) as a key population with high HIV-risk. The South African Health Monitoring Study (SAHMS) was conducted from 2013-2014 to characterize the HIV epidemic among FSW. Across many countries, including South Africa, FSW report high rates of condom use with clients. Of increasing concern are elevated risk behaviours with non-paying partners. We present findings of FSW condom use behaviours with non-paying partners.
**Methods:** We recruited 2,180 FSW aged 16 and older using respondent-driven sampling (RDS). Eligible participants took a behavioural survey, were offered rapid HIV counselling and testing, and provided blood samples for laboratory testing. Condom use with non-paying partners in the past six months was assessed through no condom used 'at last sex'. Condom use with clients was based on any reported unprotected sex. Data were analyzed in SPSS, and we present pooled analyses, unadjusted for RDS.
**Results:** Of the 2,180 FSW, 1,331 participants without non-paying partners were excluded from analysis. Of the remaining 849, 494 (58.2%) inconsistently used condoms with non-paying partners; 315 (37.1%) inconsistently used condoms with clients; 486 (57.2%) tested HIV-positive during study procedures; and 136 (16.0%) used antiretroviral therapy (ART). In bivariate associations, cohabitation; condom use with clients; marital status; 'permanent/main' designation of non-paying partner; and venues where FSW usually meets clients were associated with inconsistent condom use with non-paying partners; whereas exposure to peer education; ART use; HIV test results; perceived HIV status of non-paying partner; condom knowledge; and condom affordability were not. In multivariate analysis, cohabitation (adjusted OR (aOR)=1.93; 95%CI 1.27-2.92); inconsistent condom use with clients (aOR=1.69; 95%CI 1.23-2.32); 'permanent/main' partner status (aOR=2.59; 95%CI 1.87-3.58); and FSW who meet clients at 'street and premises-only' when compared to 'street only' (aOR=1.86; 95%CI 1.26-2.83) were associated with inconsistent condom use with non-paying partners.
**Conclusions:** Inconsistent condom use is high amongst South Africa FSW with their non-paying partners, warranting the implementation of other prevention methods like PrEP and universal treatment which could be of huge benefit to FSW with non-paying partners. Behavioural interventions need to assist FSW navigate relationship dynamics with non-paying partners to further minimise risk.

## TUPEC235

### Comparison of 48- and 96-week outcomes in adults initiating TDF+XTC+EFZ and those initiating two other NRTIs+EFZ using propensity-score matched observational cohort data and data from randomised controlled trials

G. Rutherford[1], A. Kipp[2], M.L. Lindegren[3], W. Webster[3]
[1]*University of California, Global Health Sciences, San Francisco, United States,* [2]*Vanderbilt University School of Medicine, Institute for Global Health, Nashville, United States,* [3]*Vanderbilt University, Institute for Global Health, Nashville, United States*
*Presenting author email: george.rutherford@ucsf.edu*

**Background:** Observational studies can inform clinical guidelines when RCT data are lacking. Propensity score matching has been hypothesised to better control for confounding in observational studies but has not been evaluated empirically for ART outcomes. We tested the comparability of a propensity-score matched analysis and a Cochrane systematic review of RCTs.
**Methods:** We calculated relative risks (RR) and 95% confidence intervals (CI) of two outcomes - all-cause mortality at 96 weeks and retention in care on initial regimen at 48 weeks - in ART-naïve HIV-infected adults ≥16 years old using propensity-score-matched IeDEA participants from three regions and compared results to outcomes obtained from a Cochrane systematic review of RCTs. We evaluated two regimens: TDF+XTC+EFV and 2 other NRTI combinations + EFV. For the observational analysis, we constructed propensity scores for receiving TDF+XTC+EFV based on sex, age, country and baseline CD4 count. Each individual receiving TDF+XTC+EFV was matched to one individual receiving 2NRTIs+EFV with a similar propensity score (within 0.001). We compared the propensity score-matched RR to the RR obtained from the systematic review of seven RCTs by computing RRPS/RRRCT.
**Results:** We evaluated 19,470 IeDEA participants. Risk of retention on initial regimen at 48 weeks was higher in the TDF+XTC+EFV group (RR=1.19, 95% CI 1.17, 1.21). Risk of 96-week all-cause mortality was similar in patients initiating the two regimens (RR=1.04, 95% CI 0.92, 1.18). In the systematic review, the risk of 48-week retention on initial regimen was higher in patients on TDF+XTC+EFV, but the risk of 96-week mortality was similar in the two arms. These findings were not different from those from our propensity-score-matched analysis.

| | 96-week mortality RR (95% CI) | 48-week retention RR (95% CI) |
|---|---|---|
| Crude analysis | 0.87 (0.78, 0.98) | 1.11 (1.09, 1.13) |
| Propensity score-matched analysis | 1.04 (0.92, 1.18) | 1.19 (1.17, 1.21) |
| Systematic review of RCTs | 1.00 (0.14, 7.07) | 1.14 (1.01, 1.30) |
| RRPS/RRSR | 1.04 (0.15, 7.44) | 1.04 (0.92, 1.18) |

*[Comparison of outcomes from IeDEA observational data and RCTs]*

**Conclusions:** We conclude that analysis of initial ART regimen using IeDEA data and propensity-score matching yields similar conclusions to systematic reviews of RCTs.

## TUPEC236

### Participants' beliefs about preventive efficacy in the HPTN 069/ACTG 5305 HIV trial: preliminary data using the PREMIS measure

J. Sugarman[1], D. Seils[2], L. Lin[2], K. Weinfurt[2]
[1]*Johns Hopkins University, Berman Institute of Bioethics, Baltimore, United States,* [2]*Duke University, Durham, United States*
*Presenting author email: jsugarman@jhu.edu*

**Background:** In HIV prevention trials, there is ethical concern that some participants have a "preventive misconception," an overestimate of the probability or level of personal protection afforded by participating in the trial. The purpose of this study was to collect preliminary quantitative data using a brief measure of preventive misconception (PREMIS) in an HIV prevention trial.
**Methods:** PREMIS was administered at the week 4 and 40 visits to participants in HPTN 069/ACTG 5305 [NCT01505114], a multicenter trial in the United States that included 4 arms comparing investigational maraviroc-containing regimens (vs. tenofovir/emtricitabine) for preexposure prophylaxis in men and women who have sex

with men who were at risk of HIV infection. Descriptive statistics were computed for all responses. Paired *t* tests were used to assess item responses between weeks 4 and 40.
**Results:** Responses to PREMIS items did not differ significantly between weeks 4 and 40 (n=429), so only the latter are summarized. When asked about their confidence that the study medications would prevent them from acquiring HIV, 20% did not know or were unsure; the remaining respondents expressed high confidence (median, 80%; IQR, 60%-90%). When asked which study group they thought they were in, 66.2% said they did not know. Most (62.7%) believed they were assigned randomly to their group, whereas 9.8% believed a doctor chose the best group for them. When asked how many participants out of 100 would have their chance of acquiring HIV reduced, respondents gave similar responses for all 4 study groups (all medians = 80; 30.4%-37.6% answered "don't know/unsure"). Responses among respondents who thought they knew which group they were in were similar regarding the chance of benefit for the group in which they believed they were in (median, 80 out of 100 participants; 21.2% "don't know/unsure").
**Conclusions:** These data suggest that most trial participants expressed high confidence in a prevention effect due to their belief that all of the study groups had a high likelihood of benefit. Future work should assess the relationship of responses to PREMIS, reported risk behaviors, and HIV seroconversion to place these data into context.

## Estimation of the size of HIV-infected and key populations

### TUPEC237

### Using IBBS data and consensus population size estimates of female sex workers in three South African cities to estimate treatment and biomedical prevention needs

M. Grasso[1,2], M. Sibanyoni[3], A. Manyuchi[4], A. Marr[5], T. Osmand[5], Z. Isdahl[1,2], H. Struthers[4], F. Venter[3], H. Rees[3], T. Lane[5]
*[1]University of California, San Francisco, United States, [2]Global Health Sciences, Johannesburg, South Africa, [3]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [4]ANOVA Health Institute, Johannesburg, South Africa, [5]University of California, Center for AIDS Prevention Studies, San Francisco, United States*
*Presenting author email: thomas.osmand@ucsf.edu*

**Background:** Results from a 2013-14 integrated biological and behavioral surveillance (IBBS) survey from South Africa show HIV prevalence is three to six times higher among female sex workers (FSW) than the general population. However, appropriate allocation of resources and benchmark-setting necessary to curtail the HIV epidemic among FSW has been hindered by the lack of methodologically rigorous estimates of FSW population size. For this reason, the 2013-14 IBBS included Population Size Estimation (PSE) methods to address this strategic information gap for FSW in South Africa's largest metropolitan areas of Johannesburg, Cape Town, and eThekiwni.
**Methods:** IBBS surveys recruited FSW using responding driven sampling (RDS); HIV prevalence results are presented as RDS-adjusted estimates. Multiple PSE methods were embedded in the survey, including 3 unique multiplier procedures, resulting in 4-5 point estimates for each city. We followed a Modified Delphi/consensus method to triangulate IBBS-based PSE results and previously collected population size data to derive PSEs with upper and lower plausibility bounds for each metropolitan area.
**Results:** A total of 764, 650 and 766 FSW were recruited in Johannesburg, Cape Town and eThekweni respectively. HIV prevalence estimates were high, ranging from 40%-72%. IBBS-based point estimates showed considerable variability; however, triangulated point estimates were consistent with prior PSEs, strengthening stakeholder confidence in the figures. Final consensus PSEs were 7,697 FSW (plausible range 5,000-10,895) in Johannesburg; 6,500 (4,579-9,000) in Cape Town; and 9,323 (4,000-10,000) in eThekweni (Table 1).
**Conclusions:** Current HIV prevalence estimates and PSEs demonstrate as many as 20,000 FSW in South Africa's three largest cities require HIV treatment; and as many as 17,000 would benefit from Pre-Exposure Prophylaxis. The Modified Delphi/consensus process for PSE facilitated adoption of estimates by stakeholders. We recommend this PSE method with key populations to achieve optimal stakeholder buy-in for planning and assessing programmatic impact.

| | HIV Prevalence | | Population Size | | Upper Estimates | |
|---|---|---|---|---|---|---|
| | Estimate (%) | 95% CI | Estimate | Plausibility | Require HIV treatment | PrEP candidates |
| Johannesburg | 71.8% | 56.5-81.2 | 7,697 | 5,000-10,895 | 8,847 | 4,739 |
| Cape Town | 39.7% | 30.1-49.8 | 6,500 | 4,579-9,000 | 4,482 | 6,291 |
| eThekweni | 53.5% | 37.5-65.6 | 9,323 | 4,000-10,000 | 6,560 | 6,250 |
| **Total** | | | 23,520 | 13,579-29,895 | 19,889 | 17,280 |

*[Table 1: IBBS and PSE data to estimate HIV treatment and prevention needs among FSW in three South African cities]*

### TUPEC238

### Methodological challenges in estimating the size of key populations using innovative method: network-based capture-recapture

L. Sulaberidze[1], I. Chikovani[1], N. Shengelia[1], N. Tsereteli[2], T. Sirbiladze[3], L. Tavzarashvili[3]
*[1]Curatio International Foundation, Research Unit, Tbilisi, Georgia, [2]Tanadgoma - Center for Information and Counseling on Reproductive Health, Tbilisi, Georgia, [3]Bemoni Public Union, Tbilisi, Georgia*

**Background:** Network-based capture-recapture (NCRC) method proposed by Dombrowski was introduced among methamphetamine users in the USA in 2012. This method was applied first time among Men who have Sex with Men (MSM) in Georgia and later among People Who Inject Drugs (PWIDs). The abstract presents key methodological challenges emerged during fieldwork while using this innovative method.
**Methods:** Different population size estimation (PSE) methods - 7 for MSM and 3 for PWIDs - were used in these studies, including the NCRC. The innovation of the NCRC is that the respondent provides both capture and recapture data coded for subject anonymity in a single-session, which for our studies were 210 adult MSM and 2,037 PWIDs recruited in Georgia in 2014 and 2015, respectively. Key populations were recruited through Respondent Driven Sampling using peer-referrals. For the capture phase the study participants reported their personal characteristics (approximate height, weight, hair color and ethnicity) and so called "telefunken codes" derived from the last four digits of their own mobile number. As for the recapture, the respondents provided the similar characteristics appealing to their randomly selected five contacts from the mobile phone directories. PSE study among PWIDs was linked to bio-behavioral surveillance survey. Statistical analysis was performed using Lincoln-Peterson method.
**Results:** The NCRC method provided MSM population size estimate that was in line with the estimates derived from other more established PSE methods. While for PWID this method yielded in underestimation compared to the median estimates of other PSE methods. This could be explained by difficulties to get the accurate responses on posed questions. Despite assurance of the confidentiality PWID were resistant to disclose personal characteristics of their peers, as well as giving information on the "telefunken codes". The inaccuracy of NCRC estimates was partially shown in total number of false matches, which was higher for PWIDs compared to the MSM PSE study. In addition to this refusal rate was 3.2% among PWIDs, while zero refusals were recorded among MSM.
**Conclusions:** Drug use is criminalized in Georgia. This contextual factor affected the reliability of the NCRC method among PWID. At the same time this method provided valid estimates among MSM.

## SURVEILLANCE OF HEPATITIS C (HCV) AND HIV CO-INFECTION

### TUPEC239

### CHARACTERISTICS ASSOCIATED WITH HCV MONITORING AMONG HIV/HCV CO-INFECTED ACTIVE INJECTION DRUG USERS

L. Cloutier-Gill[1], E. Wood[1,2,3], T. Kerr[1,2,3], J. Montaner[1,2,3], M.-J. Milloy[2]
*[1]University of British Columbia, Department of Medicine, Vancouver, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]University of British Columbia, Division of AIDS, Department of Medicine, Vancouver, Canada*
*Presenting author email: laurie.cloutier-gill@alumni.ubc.ca*

**Background:** Co-infection with hepatitis C virus (HCV) and HIV is common, given their shared link to injection drug use, and is associated with high rates of morbidity and mortality. Inappropriate follow-up of HCV infection among people living with HIV/AIDS can occur. However, factors that lead to HCV monitoring among the HIV-positive illicit drug users population are not known.
**Methods:** We accessed data from the AIDS Care Cohort to evaluate Exposure to Survival Services (ACCESS), an observational prospective cohort of HIV-positive illicit drug users, to determine what characteristics are associated with HCV disease monitoring. The outcome of interest was self-report of receiving HCV-related bloodwork, biopsy or ultrasound in the previous six months. We used multivariable generalized estimating equations to identify longitudinal factors associated with receiving HCV-related follow-up over the study period.
**Results:** Between December 2005 and June 2014, 432 HIV- and HCV-positive active injection drug users were recruited and contributed to 2056 interviews. Among these, 1250 (61%) contained a report of recent HCV-related follow-up from 374 (87%) of participants. Multivariable analysis showed that receipt of HIV antiretroviral therapy for at least a day in the last six months (adjusted odds ratio [AOR] = 2.40, 95% Confidence Interval [95% CI]: 1.78-3.22), reporting HCV symptoms (AOR = 1.47, 95% CI: 1.20-1.81), methadone maintenance therapy (AOR = 1.41, 95% CI: 1.14-1.74) and older age (AOR 1.02 per additional year, 95% CI: 1.00-1.03) were associated with a greater chance of HCV monitoring.
**Conclusions:** We observed that a majority of HIV-positive illicit drug users co-infected with HCV received regular monitoring for HCV-related morbidity during the study period. Factors associated with monitoring included engagement in treatment for addiction and for HIV/AIDS. Knowing which factors lead to HCV monitoring, and subsequently protect individuals from severe liver complications, could guide public health interventions. In this new era of effective and well-tolerated treatment for HCV, finding and following the individuals that would benefit from such treatment is essential.

### TUPEC240

### PREVALENCE OF SEXUALLY TRANSMITTED INFECTIONS (HIV, HSV-2, SYPHILIS AND HBV) IN PREGNANT WOMEN IN ETHIOPIA: TRENDS OVER THE PAST 10 YEARS (2005-2014)

D. Kassa, T. Tilahun, A. Ayalkebet, Y. Abreha, G. Mesfin, Y. Belay, M. Demissie, G. Gebremichael, A. Gebrexiabher, Y. Assefa
*Ethiopian Public Health Institute, Addis Ababa, Ethiopia*
*Presenting author email: dkassa2003@gmail.com*

**Background:** STIs are associated with adverse pregnancy outcomes. Aalthough prevalence data of STIs is highly pertinent for targeted intervention; there is paucity of data in Ethiopia. We determine the trends of sero-prevalence of HIV, HSV-2, Syphilis and HBV in pregnant women attending ANC clinics over the past ten years.
**Methods:** Serological tests for these STIs was conducted on plasma samples collected from pregnant women in 2005, 2007, 2009, 2012 and 2014 from 12 major cities.
**Results:** A total of 4957 pregnant women with mean ± SD of age 24±4.8 years old were included.
Data of all women irrespective of HIV status, showed a decline in the STIs by 50% in ten years (2005 to 2014):
**HIV**: 10.5% to 5.5%;
**Syphilis**: 2.5% to 1.1%;
**HSV-2**: 47.5% to 28.5%; and
**HBV**: 12.6 to 6.7%.
Although, there was a continuous decrease in HIV, syphilis and HBV in both HIV positive and negative women, the prevalence of these STIs remained higher in HIV positive women. In contrast, the prevalence of HSV-2 was increased overtime in HIV positive women while it remained at consistently lower level in HIV negative women. There was a wide disparity in prevalence of these STIs across the cities.
Data of all women showed, HBV prevalence in HIV positive younger women (15-25 years) to be higher than in older groups (26-45 years) (13.4% vs. 10.3%; p=0.10); but no difference in HBV prevalence in the HIV negative women between these age categories (6.8% vs. 6.1%; p=0.57). HSV-2 prevalence was higher in the older than in the younger age groups in both the HIV positive (65.8% vs 58.%; p=0.08) and HIV negative women (33.3% vs. 18.3%; p< 0.001).
**Conclusions:** We observed a continuous decline in HIV, HBV, HSV-2 and Syphilis in pregnant women, which showed the strength of infection prevention strategies in Ethiopia. However, the high prevalence of STIs by 2014 and the variation in prevalence among the cities indicated the need to strengthen targeted interventions. Further investigation is warranted to investigate the factors associated with the epidemiology, interaction, and clinical implication of those combined infections (HIV, HBV, HSV-2 and Syphilis) in pregnant women.

## SURVEILLANCE OF TB AND HIV CO-INFECTION

### TUPEC241

### LINKAGE TO HIV CARE AND ART INITIATION AMONG INDIVIDUALS DIAGNOSED SIMULTANEOUSLY WITH TB AND HIV IN THE UK, 2010-2014

P. Kirwan[1], Z. Yin[1], A. Skingsley[1], S. Croxford[1], J. Winter[2], S. Venugopalan[3], M. Lalor[3], L. Thomas[3], V. Delpech[1]
*[1]Public Health England, HIV & STI Department, London, United Kingdom, [2]University College London, Research Department of Infection and Population Health, London, United Kingdom, [3]Public Health England, Respiratory Diseases Department, London, United Kingdom*
*Presenting author email: peter.kirwan@phe.gov.uk*

**Background:** HIV-associated TB contributes substantially to the burden of TB-associated morbidity and mortality. Survival is improved with early antiretroviral therapy (ART), following initiation of TB therapy. UK guidelines recommend ART initiation as soon as practicable for those with a CD4< 100 cells/mm$^3$; for individuals with a CD4>100, risk of drug toxicity should be considered and may result in delayed ART initiation. We investigate the time lag between HIV diagnosis, HIV care and ART initiation among individuals diagnosed simultaneously with TB and HIV.
**Methods:** Cohort data on adults (15+ years) diagnosed with HIV in the UK between 2010 and 2014 were linked to the national Enhanced TB surveillance system. Individuals were considered simultaneously diagnosed (TB-HIV) if they had a TB and HIV diagnosis within three months. Time lags were calculated using TB diagnosis date, first CD4 date and ART initiation date. Viral load (VL) suppression was defined as < 200 copies/ml.
**Results:** Between 2010 and 2014, 807 HIV-diagnosed adults were diagnosed with TB; 523 (65%) were simultaneous diagnoses. Median time from TB diagnosis to HIV care among TB-HIV individuals was 5 days [IQR 1-18.5] with 85% linked to care within one month, similar to 6 days [0-20] and 81% among HIV-diagnosed individuals without TB. Median time lag to ART initiation was 27 days [15-53] and 41 days [20-81] for TB-HIV individuals with a CD4< 100 and 100-349, respectively, similar to that of HIV-diagnosed individuals without TB in the same CD4 strata. Among those with a CD4>350, TB-HIV adults started ART sooner than HIV-diagnosed adults without TB (median 77 days [41-281] vs 388 days [70-967]). Following ART initiation, 95% of TB-HIV adults achieved VL suppression within 3-15 months regardless of CD4-cell count, similar to HIV-diagnosed adults without TB.
**Conclusions:** Linkage to HIV care and ART initiation are prompt among TB-HIV adults. At the population level, ART initiation was not significantly delayed among TB-HIV individuals, indicating increasing recognition of the importance of early ART initiation in TB-HIV adults with a CD4< 350, over potential risks of drug toxicity. Among TB-HIV individuals with a CD4>350, delaying ART until after the intensive phase of TB treatment is the norm.

## ASSESSMENT OF POPULATION VIRAL LOAD IN EPIDEMIOLOGY STUDIES

### TUPEC242

#### VIRAL LOAD METRICS: AN ADDITIONAL BENEFIT FOR HIV SURVEILLANCE?

R. Bolijn[1], E. Op de Coul[1], A. Van Sighem[2], M. Kretzschmar[1,3], J. Heijne[1]
*[1]National Institute for Public Health and the Environment, Centre for Infectious Disease Control, Bilthoven, Netherlands, [2]Stichting HIV Monitoring, Amsterdam, Netherlands, [3]Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands*
*Presenting author email: eline.op.de.coul@rivm.nl*

**Background:** The use of viral load (VL) metrics as a tool for HIV surveillance has been debated, in particular how these quantities should be measured and interpreted. In this study, various in-care viral load (ICVL) and other VL metrics were compared in their time trends and their association with numbers of newly diagnosed HIV cases over time. We aimed to obtain more insight into the possible additional value of VL metrics for HIV surveillance.
**Methods:** Data from HIV patients registered in the national observational Dutch ATHENA cohort from 2002-2014 were used, including viral load measurements, CD4 cell counts, and epidemiological information. Various VL metrics were compared: log VL at diagnosis, five different ICVL metrics (e.g. median of the median, and mean of the mean, first, last, highest, of the patients' VLs in a year), the proportion of patients with transmission risk (>400 copies/ml), and with a suppressed VL (≤200 copies/ml) per year. Differences in VL metrics among subgroups were tested using Kruskal-Wallis tests and Wilcoxon rank sum tests. Negative binomial regression analyses were performed to study the association between the VL metrics and numbers of newly diagnosed HIV cases one, two, and three years later.
**Results:** Differences in all VL metrics were found for modes of transmission, region of origin, region of current residence, SES, and population density. Log VL at diagnosis increased over time and was negatively associated with numbers of newly diagnosed HIV cases two and three years later ($p < 0.001$). The different ICVL metrics showed similar decreasing trends, except for the median of the median log VL, which remained constant. Of the five ICVL metrics, the mean of the mean log viral load per year was chosen for further analyses. The strongest association was found between this ICVL metric and numbers of new HIV diagnoses in subsequent years, as compared to the other VL metrics.
**Conclusions:** VL metrics may have additional value for HIV surveillance to identify subgroups or locations with reduced treatment uptake or to provide insight in time between infection and diagnosis.

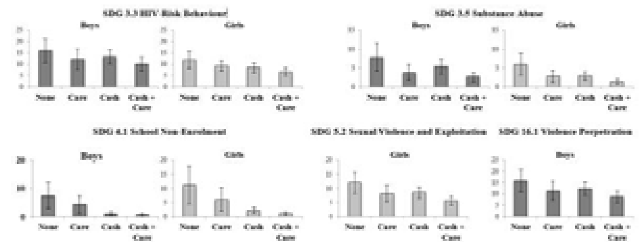
## ASSESSING IMPACT/COST-EFFECTIVENESS OF STRUCTURAL INTERVENTIONS

### TUPEC243

#### CAN SUSTAINABLE DEVELOPMENT GOAL 1.3 MITIGATE ADOLESCENT HIV RISKS?

L. Cluver[1], M. Orkin[2], M. Boyes[3], A. Yakubovich[4], L. Sherr[5]
*[1]Oxford University and University of Cape Town, Social Policy and Intervention, Cape Town, South Africa, [2]University of the Witwatersrand, DST-NRF Centre of Excellence in Human Development, Johannesburg, South Africa, [3]Curtin University, School of Psychology, Perth, Australia, [4]University of Oxford, Social Policy and Intervention, Oxford, United Kingdom, [5]University College London, London, United Kingdom*
*Presenting author email: lucie.cluver@spi.ox.ac.uk*

**Background:** The shift from MDGs to SDGs may risk reduction of HIV-specific resources, alongside rising adolescent HIV-infection and AIDS-deaths. But particular SDGs may also have large-scale potential to improve HIV outcomes. This study examines whether SDG goal 1.3: the implementation of national social protection systems, can impact key adolescent HIV risks in South Africa.
**Methods:** Longitudinal survey of adolescents (10-18 years) between 2009 and 2012 during a national adolescent social protection scale-up. Census areas were randomly selected in two urban and two rural health districts in two South African provinces, including all homes with a resident adolescent. Gender-disaggregated multivariate analyses assessed household receipt of 'cash' (i.e. cash transfers, free school) and 'care' (i.e. good parenting, teacher support) social protection, and HIV-related indicators that fell within five SDG goals, using multivariate logistic regression and marginal effects models.
**Results:** Social protection was associated with significant adolescent risk reductions in 11 of 17 gender-disaggregated HIV-outcomes that are also SDG indicators: hunger, HIV-risk behavior, tuberculosis, substance abuse, educational access, sexual exploitation, sexual and reproductive health and violence perpetration (SDGs 2, 3, 4, 5 and 16). For tuberculosis and mental health, and for boys' sexual exploitation, no effects were found and more targeted or creative means will be needed to reach adolescents on these key HIV-related risks.



*[SDG Graphs]*

**Conclusions:** National social protection systems are not a panacea, but findings suggest that they have multiple associations with reducing adolescent HIV risks. In moving beyond the MDGs, we need to act on the potential for utilising the Sustainable Development Goals to maximise the HIV/AIDS response.

### TUPEC244

#### IMPACT OF COMMUNITY-LED STRUCTURAL INTERVENTIONS FOR VULNERABILITY REDUCTION LEADING TO PRIMARY RISK REDUCTION OF HIV IN 5 STATES OF INDIA

R. Deshpande[1], E. Daniel[2], P. Patel[2], R. Narayanan[3], S. Karkal[4]
*[1]Swasti Health Resource Center, Monitoring, Evaluation and Learning, Pune, India, [2]Swasti Health Resource Center, Monitoring, Evaluation and Learning, Bangalore, India, [3]Catalyst Management Services, Bangalore, India, [4]Swasti Health Resource Center, Bangalore, India*
*Presenting author email: rohan@swasti.org*

**Background:** Swasti along with its sister organizations of Vrutti and Catalyst Management Services are engaged by BMGF to lead the Avahan India AIDS Initiative (April 2014 to March 2017) across five high HIV prevalence states (Andhra Pradesh, Karnataka, Maharashtra, Tamil Nadu and Telangana) of India. Two key factors that shaped the design of phase III were, vulnerability reduction needs to compliment primary risk reduction to ensure effective sustainable results in HIV prevention and community institutions need to be strengthened further to for sustainability. 4 program strategies- safety, security and justice, social protection, financial security and community institution and strengthening-are implemented. The 4 pillars are mutually reinforcing, the first 3 focusing on the individual and ecosystem and last focusing on organization (agency).
**Methods:** Member Engagement and Communication is a systematic and continuous process undertaken from April to September 2015 by Field Workers of 84 Community Organization in their respective intervention areas covering 110 thousand female sex workers in order to collect the information required to identify their needs, prepare program strategies and serve as baseline for impact assessment.
The tool captured demographic and socio-economic profile of respondents and their access to safety, security, and justice, social protection and financial security services. A composite scale was used to compute vulnerability reduction intervention coverage score (range 3 to 15) for every respondent. Data collected was statistically analyzed using Stata 12.0. Multivariate analysis was used to determine the predictors of score and whether, after adjustment of covariates, outcomes (regular HIV testing and current history of STI) differed among the women of different levels of coverage score.
**Results:** Analysis shows that the women of high vulnerability reduction intervention coverage score were more likely (Odds Ratio 1.2) to undertake regular (6 monthly) testing for HIV and less likely (Odds Ratio 0.76) to be suffering from STI. The differences were statistically significant ($p < 0.001$).
**Conclusions:** The study provides an evidence of vulnerability reduction interventions leading to decreased risk of violence, increased social protection and financial security as well as empowerment to negotiate and make choices for safe sex behavior, reduced risk to HIV infection and sustained impact of HIV prevention.

## GENDER SENSITIZATION, EMPOWERMENT AND VIOLENCE REDUCTION

### TUPEC245

### DEVELOPING AND INTEGRATING GENDER-BASED VIOLENCE SCREENING PROGRAM WITHIN COMMUNITY ORGANIZATIONS

N. Persaud[1], F. Harris[1], A. Dobkowski[2]
*[1]Advancing Partners & Communities, Georgetown, Guyana, [2]Peace Corp, Georgetown, Guyana*
*Presenting author email: npersaud@apcguyana.com*

**Background:** In Guyana, women and key populations (men who have sex with men, transgender individuals, sex workers) experience high levels of HIV and gender-based violence (GBV). Guyana's 2014 Bio-behavioural Surveillance Survey found that one quarter to one third of sex workers experienced rape (25.2% male, 25.1% female and 31.1% transgendered). Stigma and criminalization of these behaviours further exacerbate the experience of violence, and hinder access to HIV prevention and support services. Client-friendly, integrated HIV and GBV services would alleviate service barriers and expand referrals to support networks.
**Methods:** In 2014, Advancing Partners & Communities, supported by International Centre for Research on Women, commenced a nine-week pilot intervention at five sites to examine the feasibility of integrating GBV services within HIV services provided by community organisations. Pilot methodology involved adapting an existing GBV screening tool and referral programme, including situational analysis, a resource booklet, a directory of services and programme protocol. Key population members and PLHIV were offered screening while they accessed HIV counselling, testing or care and support services. Community organisation providers received gender-sensitivity and GBV-specific training and onsite mentoring, allowing them to sensitise their local support organisations.
**Results:** Of the 111 persons screened (76 female, 35 male), 51% (56) had experienced some form of violence in the preceding 12 months. 80% (45) of these reported experiencing emotional violence, 52% (29) physical, 39% (22) sexual and 46% (26) psychological, while 25% reported experiencing all forms of violence. Women were four times more likely to experience violence than men. About half (29/56) of the clients who screened positive for GBV were referred to services outside the pilot site, but only 14% (4/29) confirmed accessing these.
**Conclusions:** The pilot demonstrated the effectiveness of an integrated approach in identifying survivors of violence and gathering valuable information. It allowed community providers and referral agencies to have greater awareness of sexuality and gender and how HIV and violence are interlinked. Additionally, the pilot fostered relationships between providers and referral networks, promoting a more gender sensitive and client friendly environment. It acted as an impetus to initiate broader community-health system collaboration and improved response to HIV-related vulnerability.

### TUPEC246

### CREATING ENABLING ENVIRONMENT TO REDUCE VULNERABILITIES OF MSM TOWARDS HIV/AIDS THROUGH KEY STAKEHOLDER'S SENSITIZATION

T. Chopade, H. Mhaprolkar, V. Anand
*The Humsafar Trust, Capacity Building, Mumbai, India*
*Presenting author email: tinesh.hst@gmail.com*

**Background:** Homosexuality—a criminal offense in India due to prevailing sodomy laws—invites further stigma and discrimination due to cultural and social influences. MSM are disproportionately impacted by HIV and remain vulnerable due to hostile environments that prevent access to healthcare and legal aid. Healthcare-legal stakeholders play a key role in creating enabling environments for MSM. Thus stakeholder sensitization is crucial and needs focus.
**Description:** The Humsafar Trust is Sub-Recipient for Global Fund Round-9 funded Project DIVA which focuses on to improve policy environment with regards to MSM, transgender and capacity building of the organizations implementing MSM HIV interventions with a focus on stakeholder sensitization conducted via workshops highlighting MSM issues with various training models and methodologies comprising discussion, presentation, case studies, and visual aid thus enabling organizations to engage in policy development, advocacy initiatives, and rapport building with stakeholders.
**Lessons learned:** Twenty one community-led and managed workshops involving 655 stakeholders (209 State AIDS Control Society Officials, 272 police and law enforcement personnel, 78 judiciary members, 96 Media personnel's) were conducted from October 2014-December 2015 on MSM issues in North, North Eastern areas. These workshops highlighted chief community concerns such as violence, harassment, invisibility and sensitized stakeholders with community participation and involvement. Stakeholders reported better understanding of MSM issues after the sensitization workshops.
**Conclusions/Next steps:** Community-led stakeholder sensitization is key in creating and fostering rational attitudes toward MSM. Enabling environments further empower MSM to seek healthcare and legal aid thus reducing their vulnerabilities to violence and HIV. Community involvement and wider replication of similar activities is strongly needed to promote human rights, overall wellbeing and social justice toward marginalized communities such as MSM.

| Sr. No. | Stakeholders | Number of Workshops | States | No. of Participants | Total |
|---|---|---|---|---|---|
| 1 | Govt. Official | 10 | Arunachal Pradesh | 22 | 209 |

### TUPEC247

### ROLE OF BUILDING CAPACITIES FOR SEXUAL CONSENT IN REDUCING HIV VULNERABILITY AMONG MSM AND TRANSGENDER WOMEN IN SOUTH ASIA

P. Dhall[1], P. Prabhughate[2], J. Varghese[2]
*[1]Varta Trust, Leadership and Management of the Organization, Kolkata, India,*
*[2]International Center for Research on Women (ICRW), HIV and Gender, Mumbai, India*
*Presenting author email: pawan.dhall@gmail.com*

**Background:** Behaviour change communication (BCC) efforts in HIV interventions targeted at men who have sex with men (MSM) and transgender (TG) women in South Asia have traditionally not emphasized negotiation of sexual consent. A seven-country South Asian regional study supported by UNDP on gender-based violence (GBV) faced by MSM and TG women suggests that addressing individual and community perceptions, skills and capacities around sexual consent has a key role in reducing HIV vulnerability. This abstract looks at data in particular from Afghanistan, India and Pakistan.
**Methods:** Ten FGDs conducted with MSM and TG women in Afghanistan, India and Pakistan used case vignettes to elicit narratives of GBV among study participants. The FGDs were supported by key informant interviews and literature review. Data was analyzed using a coding tree emergent from the reading of transcripts, and subsequently Atlas-ti software. Study protocols were reviewed by ethics research committees in each of the study countries. Training on gender and sexuality concepts and research ethics preceded the study.
**Results:** Analyses reveal that consent provided by MSM and TG women for unprotected sex with multiple male partners (including commercial partners) has several contexts: Financial compulsions around livelihood, maintaining intimate partners, meeting monetary expectations of community leaders; peer pressure to live up to norms around femininities and masculinities; uncertainty around availability of partners in a safe environment; dealing with stakeholders with institutional power; escape from incessant family and intimate partner violence; and the influence of substance use and mental ill health. Opinions on what constitutes consent and withdrawal of consent vary widely. Narratives of abusive first-time sexual encounters with male partners are frequent. These contexts constitute pathways through which GBV results in increased HIV exposure.

Late Breaker Posters
Author Index

**Conclusions:** Counselling and other BCC strategies in HIV interventions for MSM and TG women must go beyond exclusive emphasis on condom usage and STI/HIV testing and treatment to cover contexts that lead to unprotected sex and poor health seeking behaviour. They must facilitate access to economic inclusion, legal aid and mental health services and develop capacities in programme beneficiaries to provide well-considered consent and withhold or withdraw it as an HIV prevention strategy.

## TUPEC248

### ENHANCING STRUCTURAL INTERVENTIONS THROUGH BOYFRIEND'S FORUM FOR MITIGATING GENDER-BASED VIOLENCE AMONG FEMALE SEX WORKERS IN HIV INTERVENTIONS

T. Shittu[1], O. Oderinde[1], A. Ojoye[1], J. Ibitoye[2], S. Ikani[2]
*[1]Society for Family Health, HIV/AIDS Prevention, Lagos, Nigeria, [2]Society for Family Health, Research, Measurement and Results, Lagos, Nigeria*
*Presenting author email: dshittu@hotmail.co.uk*

**Background:** Gender based violence (GBV) has been recognised as a global public health and human right setback leading to elevated rates of morbidity and mortality. Violence which includes sexual abuse and physical assault against female sex workers (FSWs) has been reported to increase the risk of HIV infection and sexually transmitted infection, resulting in reduced control of FSWs to negotiate HIV risk reduction practices with their partners (boyfriends). Low condom use during sex with boyfriends among FSWs represents a potential bridge for HIV transmission of HIV infection to the general population. This paper points out that physical and sexual violence against FSWs committed by boyfriends can be mitigated through structural interventions using boyfriend's forum.
**Description:** Society for Family Health is implementing a five year MARPs project funded by USAID in Nigeria. In Lagos State, the project is implemented in 15 Local Government Areas. In line with the National HIV Strategic Framework, structural interventions using boyfriend's forum was conducted as small group discussions.
The objectives of the boyfriend's forum were to: involve the partners of the FSWs in HIV interventions; create an enabling environment to support safer sex practices and promote sustainability of behaviour change; address emerging issues, social crisis and mitigate violence that affects the FSW communities. In conducting boyfriend's forum, each FSW was requested to invite her boyfriend to the small group discussion where issues' surrounding violence and HIV were discussed. Information gathered were collated, analysed using simple tools and disseminated to the FSW community.
**Lessons learned:** This forum created the opportunity of tackling the issue of non condom use by FSWs with boyfriends supporting the use of condom as at last sexual act. Involvement of boyfriends in structural interventions has impacted on reduction in violence experienced by FSWs. This discussion offers a cost effective way of involving partners of female sex workers in HIV interventions.
**Conclusions/Next steps:** HIV interventions targeting FSWs should encourage a forum among FSWs and their boyfriends to address the role of GBV in HIV related risk behaviours and infection thereby contributing to the reduction of HIV prevalence.

# COLLECTIVIZATION, MOBILIZATION, STIGMA REDUCTION PROGRAMMES

## TUPEC249

### AFRICAN AMERICAN HIV UNIVERSITY, SCIENCE AND TREATMENT COLLEGE: A MODEL TO ADDRESS HIV-RELATED STIGMA AND LOW HEALTH LITERACY IN BLACK COMMUNITIES

R. Israel
*Black AIDS Institute, Los Angeles, United States*

**Background:** Black Americans have the most severe burden of HIV among all racial/ethnic groups in the nation. Research shows that lack of scientific literacy, stigma, conspiracy beliefs and misconceptions of HIV have presented considerable barriers to HIV prevention strategies among Black Americans. Additionally, the Black AIDS Institute's recent report on the state of HIV science and treatment literacy among the HIV workforce indicates that Black members of the workforce score significantly lower than their white counterparts on HIV knowledge questions. The African American HIV University (AAHU) Science and Treatment College (STC) is an intensive training and fellowship program that responds to these barriers in Black communities.
**Description:** Aimed at strengthening organizational and individual capacity to address the HIV/AIDS epidemic in Black communities, the African American HIV University (AAHU) Science and Treatment College (STC) is a comprehensive training fellowship and scholarship program. The program is designed to decrease stigma and misperception and increase the engagement and mobilization of the Black community in HIV prevention and treatment services. The STC curriculum prepares community-based and AIDS service organizations (CBOs/ASOs) to serve as liaisons between people living with HIV/AIDS (PLWHA). STC focuses on HIV and its relationship to human biology, virology, pharmacokinetics, epidemiology, and treatment strategies.
**Lessons learned:** An evaluation of the 2013-2014 AAHU STC cohort reveals a substantial increase of HIV science and treatment literacy among the Fellows (38% increase), their organizations (54% increase) and the communities they serve (42% increase). Fellows reported being more prepared to educate their organizations and communities on HIV science, provide exemplary linkage to care services to their clients and implement HIV programming at the local and regional levels due to skills learned at AAHU STC. The 2014-2015 cohort shows similar increases in knowledge (52% increase). The data from the 2015-2016 is forthcoming.
**Conclusions/Next steps:** AAHU is a successful model in improving science and treatment literacy of Black HIV/AIDS workforce and organizations serving Black PLWHA. AAHU STC incorporates UNAIDS' capacity building recommendations by utilizing both long and short term training and leadership strategies. Additionally, AAHU STC responds to the UNAIDS charge to increase HIV education among those serving highly-impacted communities.

# POSITIVE HEALTH, DIGNITY, PSYCHOLOGICAL WELL-BEING AND MENTAL HEALTH

## TUPED250

### ENHANCING POSITIVE OUTCOMES FOR POSITIVE PEOPLE: HOW DO WE PROMOTE LIFE SATISFACTION AMONG HIV+ LOW INCOME MEN WHO HAVE SEX WITH MEN AND PEOPLE WHO USE INJECTION DRUGS IN TAIWAN?

A. Lacombe-Duncan, D.-M. Chuang
*University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada*
*Presenting author email: ashley.lacombe.duncan@utoronto.ca*

**Background:** Increased life satisfaction may promote the health and wellbeing of people living with HIV (PLWH). Studies suggest several factors that may influence life satisfaction, including self-esteem, community engagement, and HIV-related stigma, which may vary across country and may be impacted by social and structural barriers that are differentially experienced by marginalized populations (e.g. men who have sex with men; MSM, people who inject drugs; PWID). The purpose of this study was to assess correlates of life satisfaction among those most affected by HIV/AIDS in Taiwan: MSM and PWID, in order to inform contextually-relevant interventions to improve life satisfaction for these marginalized populations.
**Methods:** During summer 2011, we conducted a cross-sectional, self-administered, paper-and-pencil survey among a convenience sample of MSM and PWID recruited from community-based organizations and local prisons across Taiwan. Items included socio-demographics and standardized measures of medication adherence, AIDS knowledge, empowerment, HIV community participation, HIV-internalized stigma, and life satisfaction. Two multiple linear regressions (1-MSM; 2-PWID) were conducted with life satisfaction as dependent variable.
**Results:** PWID (n=177) were significantly older, had lower SES, were more likely to live in a correctional facility, and had a lower mean life satisfaction score compared to MSM (n=178). Correlates in the MSM model accounted for 40.2% of the variance in explaining life satisfaction ($F(15, 147)=8.27$, $p< .001$). Higher personal empowerment ($\beta=0.39$, $p< .001$), higher interpersonal empowerment ($\beta=0.22$, $p< .05$), and higher HIV community participation ($\beta=0.15$, $p< .05$) were significantly associated with greater life satisfaction. Correlates in the PWID model accounted for 25.8% of the variance in explaining life satisfaction ($F(17, 139)=4.20$, $p< .001$). Higher personal empowerment ($\beta=0.23$, $p< .05$) and lived in a correctional institution ($\beta=0.05$, $p< .05$) were associated with greater life satisfaction.
**Conclusions:** These findings indicate that empowerment-oriented interventions aimed at promoting personal empowerment may increase life satisfaction for MSM and PWID in Taiwan. Life satisfaction among MSM may be further increased by addressing interpersonal empowerment and promoting HIV community engagement. More research is necessary to fully understand the experiences of Taiwanese PWID and to continue to fight not only for the health of these individuals but for their full participation in a satisfying life.

## TUPED251

### LIVING WITH HIV IN SWEDEN: A SURVEY STUDY ON LIVING SITUATION AND QUALITY OF LIFE

A. Ekström[1], C. Deogan[2], L. Lindberg[3], M. Wallin[3], G. Hök[3], L. Mannheimer[3,4]
[1]*Karolinska Institutet, Solna, Sweden, [2]Public Health Agency of Sweden, Stockholm, Sweden, [3]Public Health Agency of Sweden, Solna, Sweden, [4]Karolinska Institutet, LIME, Solna, Sweden*
*Presenting author email: charlotte.deogan@folkhalsomyndigheten.se*

**Background:** The aim of the study was to explore quality of life among people living with HIV and it is the first of its kind and size in Sweden.
**Methods:** In total, 1096 individuals responded to an anonymous survey which included different areas of life regarding self-rated quality of live. The study was performed at 15 health care units in Sweden, representing 75 per cent of the HIV care in the country, as well as two needle and syringe exchange clinics in Stockholm. The respondents are representative of the different sub groups of people living with HIV in Sweden.
**Results:** The participants reported high rates of general quality of life and 60% rated their general quality of life as 7 or above on the general quality of life scale that ranges from 0-10. However, the satisfaction with one's economic situation was low and 70% of respondents were also displeased with their sex life, mainly due to difficulties to engage in sexual relationships. Twenty-five per cent had stopped having sex with others after being diagnosed, and another 25% of the respondents reported that HIV had had a negative impact on their ability to experience pleasure in relation to intercourse. Two aspects of HIV stigma significantly correlated with lower quality of life; other people's attitudes to their HIV infection (concerns over public attitudes to people living with HIV) and self-stigma (negative self-image because of the HIV infection). No correlation was shown between quality of life and sex/gender, age, country of birth or city of residence. However, the results showed that psychological symptoms, psychiatric side effects from HIV medication, substance abuse and high consumption of alcohol, homelessness and low income correlated with lower quality of life.
**Conclusions:** Quality of life among people living with HIV in Sweden is generally high however the results show that quality of life is negatively affected by the social aspects of being open with your HIV status, issues of stigma, possibilities for intimate relationships and a sex life, rather than affected by the medical factors of the infection.

## TUPED252

### CHANGES IN QUALITY OF LIFE AMONG PLHIV IN ESTONIA FROM 2005 TO 2013

L. Lemsalu[1,2], K. Rüütel[1], L. Lõhmus[1], K.-T. Laisaar[2], A. Uusküla[2]
[1]*National Institute for Health Development, Tallinn, Estonia, [2]University of Tartu, Tartu, Estonia*
*Presenting author email: liis.lemsalu@tai.ee*

**Background:** The HIV epidemic in Estonia erupted among PWID in early 2000s. Although HIV incidence has fallen from 108 to 21 per 100,000 (in 2001 and 2015, respectively), Estonia still has the highest incidence in Europe.
The aim of our study was to evaluate quality of life (QoL) of PLHIV in Estonia throughout the epidemic.
**Methods:** Data from series of cross-sectional studies (2005, 2008, 2013) using convenience sampling and standardised data collection methodology were analysed. Patients from three outpatient HIV clinics providing 90% of care to PLHIV in Estonia were recruited during routine visits to the clinic. PLHIV at least 18 years old and aware of their HIV-positive serostatus for at least three months were eligible. Data were gathered by self-administered questionnaire. QoL was measured with WHOQoL-HIV Bref. Descriptive statistics with $\chi^2$-test/ANOVA, and ANOVA followed by Tukey's range test were used for statistical analyses.
**Results:** Table 1 shows differences among PLHIV receiving outpatient care in Estonia and Table 2 analyses changes in QoL throughout the years.

| | 2005 | 2008 | 2013 | *p* |
|---|---|---|---|---|
| N | 446 | 441 | 800 | |
| Men (vs. women) | 237 (53) | 225 (51) | 471 (59) | .020 |
| Age* | 26±7 | 29±6 | 34±8 | <.001 |
| Russian ethnicity (vs. Estonian, other) | 381 (86) | 380 (86) | 676 (85) | .899 |
| Employed (vs. unemployed, studying, other) | 131 (29) | 136 (31) | 323 (41) | <.001 |
| On ART | 108 (24) | 219 (50) | 717 (91) | <.001 |
| >5y since first HIV+ test result (vs. <5 years) | 39 (9) | 192 (46) | 619 (77) | <.001 |
| HIV acquired through IDU (vs. sexual, other) | 267 (60) | 235 (54) | 368 (49) | <.001 |
| Note. Data presented as n (%), * data presented as mean±SD. | | | | |

*[Table 1. Socio-demographic characteristics of participants by year of study, Estonia]*

| | 2005 | 2008 | 2013 | *p* | *Post Hoc* |
|---|---|---|---|---|---|
| Physical | 13.4±3.6 | 13.3±3.3 | 13.9±3.4 | .002 | 2013-2005; 2013-2008 |
| Psychological | 13.7±2.7 | 13.2±2.8 | 12.4±3.2 | <.001 | 2013-2005; 2013-2008 |
| Independence | 13.8±3.4 | 14.2±3.3 | 12.5±3.4 | <.001 | 2013-2005; 2013-2008 |
| Relationships | 13.5±3.2 | 13.4±3.4 | 13.2±3.7 | .306 | |
| Environment | 12.2±2.4 | NA | 13.4±4.5 | <.001 | 2013-2005 |
| Beliefs | 13.6±3.3 | 13.8±3.3 | 14.1±3.5 | .055 | |
| Overall QoL | 3.1±0.9 | 3.1±0.9 | 3.1±0.8 | .548 | |
| Health-related QoL | 2.5±1.0 | 2.5±1.0 | 2.8±1.0 | <.001 | 2013-2005; 2013-2008 |
| Note. Data presented as mean±SD. Post Hoc analyses show pairs of studies with statistically significant difference. | | | | | |

*[Table 2. Quality of life among PLHIV in Estonia using WHOQoL-HIV Bref]*

**Conclusions:** We observed significant shifts in QoL of PLHIV in Estonia in 8 years: environmental, physical and health-related QoL were rated higher but independence-related and psychological QoL lower in 2013 vs. 2005. Differences in studies' sample characteristics indicate to an ageing cohort. Our results illustrate the necessity to monitor routinely actual needs of a changing HIV population and adjust services accordingly to promote best possible QoL. Currently, more attention is needed on actions to improve psychological well-being and manageability of everyday activities among PLHIV in Estonia.

## TUPED253

### EFFECTIVENESS OF SUPPORTIVE COUNSELLING FOR CLIENTS RECEIVING ART IN PUBLIC HEALTH FACILITIES IN BOTSWANA

T. Paul[1], R. Stockton[2], K. Morran[3], E. Mokalake[4]
[1]*Institute of Development Management (IDM)-Botswana, Public Health, Gaborone, Botswana, [2]Indiana University, Counselling Psychology, Bloomington, United States, [3]Indiana University, Counselling Psychology, Indianapolis, United States, [4]Institute of Development Management-Botswana, Public Health, Gaborone, Botswana*
*Presenting author email: paul@idmbls.com*

**Background:** About 320,000 people are living with HIV in Botswana; 24.8% being adults aged 15-49. In 1999 the Government of Botswana expanded its response to HIV/AIDS by providing comprehensive care including provision of free antiretroviral treatment (ART). By 2013; approximately 69% of adults were receiving ART and supportive counselling. The study focused on clients' perception on the quality and scope of supportive counselling services received.
**Methods:** The study employed a mixed method of qualitative and quantitative survey. A three part survey was designed to assess client satisfaction with counselling. A total of 328 clients on ART receiving supportive counselling were interviewed from 10 randomly selected sites that included hospitals and clinics with IDCC services. Supportive counselling components surveyed included: a) personal support system b) goal setting c) HIV educational materials d) benefits of counselling e)disclosure f)quality of life g) perception of counselling relationship h)access to counselling and supportive services i) dealing with stigma. Principal Component Analysis was used to arrive at component-based scores which were further explored using correlation and analysis of variance (ANOVA) procedures.
**Results:** Participants were positive about the benefits of counselling with 74% agreeing or strongly agreeing. However 71% and 67% reported that counselling was unhelpful in dealing with work and financial issues. A significant proportion (30%) reported limited access to counsellors during crisis. The majority of participants were satisfied with family and friends as support system. On disclosure of HIV status, most participants (66%) could not talk to their employers about their positive status and 12% could not disclose to their spouses. On perception of social stigma 38% feel ashamed of their status while 21% believe people treat them differently when they know their status.
Female participants had a positive outlook on life and higher ratings of acceptance by family and friends than did males.
**Conclusions:** With the exception of social stigma, participants perceived counselling as effective. They were particularly positive about the HIV educational materials received, their current quality of life and the support received from family and friends. However additional resources and client focused interventions are needed to adequately meet the supportive counselling gaps.

### QUALITY OF LIFE IN HIV+ PATIENTS: RESULTS FROM THE HIV HEART COHORT STUDY

J. Biermann[1,2], T. Neumann[1], N. Reinsch[1], V. Holzendorf[3], D. Schadendorf[4], N.H. Brockmeyer[5], M. Hower[6], J. Wasem[2], S. Esser[7]
*[1]University Hospital Essen, Department of Cardiology, Essen, Germany, [2]University of Duisburg - Essen, Institute for Health Care Management and Research, Essen, Germany, [3]University Leipzig, Clinical Trial Centre Leipzig - Coordination Centre for Clinical Trials (ZKS Leipzig - KKS), Leipzig, Germany, [4]University Hospital Essen, Department of Dermatology and Venerology, Essen, Germany, [5]Ruhr University Bochum, Immunological Ambulance, Department of Dermatology and Venereology, Bochum, Germany, [6]Hospital Dortmund, ID Ambulance, Medical Clinic North, Dortmund, Germany, [7]University Hospital Essen, HIV/STD-Ambulance, Department of Dermatology and Venerology, Essen, Germany*
*Presenting author email: stefan.esser@uk-essen.de*

**Background:** The HIV-infection has changed from an acute life-threatening disease to a chronic infection and affects quality of life. The purpose of this analysis was to evaluate health-related quality of life (HRQoL) in the patient sample of the German HIV HEART study.
**Methods:** The HIV HEART cohort study is a prospective observational study that investigates the frequency and clinical course of cardiac disorders in HIV+ outpatients. HRQoL was assessed by the SF-36. We analysed patients who completed the SF-36 at baseline and at the 7.5-year follow up in order to identify factors that influence HRQoL by linear regression models.
**Results:** Of 1.496 HIV-positive patients 298 fulfilled the SF-36 at baseline and at the 7.5 years follow-up. At baseline, the average age was 43.7±9.1 years, 88.9% were men, 29.2% in CDC stage C, and 44.6% in the immunological stage III. Mean HRQoL according to the physical health summary (PHS) was 49.0±9.2 (baseline) and 47.1±10.3 (7.5years, p=0.022). Results for the mental health summary (MHS) indicate increases (43.9±11.8; 45.4±12.0, p=0.16). Age was a negative predictor for PHS (-1.7,p=0.01) and a higher education level a positive. Depression (-5.0,p=0.007) was a negative determinant for MHS, smoking and hepatitis tend to be negative, while age and HIV-duration were marginally positive. The subscales indicate living alone as a negative and a HIV-RNA below the detection-limit as a positive predictor.
**Conclusions:** HRQoL in patients with HIV may be significantly affected by age, HIV-specific measurements, sociodemographic factors (education-level) and lifestyle factors (smoking). Coinfection with hepatitis or depression decreases HRQoL.

## TUPED255

### RESILIENCE AMONG ADOLESCENTS INFECTED AND AFFECTED BY HIV: DIFFERENCES IN BEHAVIORAL AND PSYCHOLOGICAL OUTCOMES

A. LoVette[1], C. Kuo[1,2,3], J. Pellowski[4], A. Harrison[1], C. Mathews[3,5], D. Operario[1,2,6], W. Beardslee[7], L. Cluver[3,8], D. Stein[3], L. Brown[2,4]
*[1]Brown University School of Public Health, Department of Behavioral and Social Sciences, Providence, United States, [2]Lifespan/Tufts/Brown Center for AIDS Research, Providence, United States, [3]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [4]Alpert Medical School of Brown University, Department of Psychiatry and Mental Health, Providence, United States, [5]South African Medical Research Council, Health Systems Research Unit, Cape Town, South Africa, [6]Brown University School of Public Health, Center for Alcohol and Addiction Studies, Providence, United States, [7]Boston Children's Hospital & Judge Baker Children's Center & Harvard Medical School, Department of Psychiatry, Boston, United States, [8]Oxford University, Department of Social Policy and Intervention, Oxford, United Kingdom*
*Presenting author email: ashleigh_lovette@brown.edu*

**Background:** Psychological and behavioral outcomes among adolescents infected and affected by HIV have been primarily studied using risk-focused frameworks. Yet, adolescents living with HIV, affected by familial HIV, and who have been orphaned by AIDS exhibit remarkable resilience in the context of difficult circumstances. Current research provides little evidence on how resilience relates to psychological and behavioral outcomes of adolescents infected and affected by HIV. We need to build our scientific understanding of how potentially vulnerable adolescents thrive in the context of risk.
**Methods:** We recruited N=195 adolescents 13-15 years through systematic house-to-house sampling for a cross-sectional survey in Khayelitsha, South Africa to determine the relationship between resilience, and psychological and behavioral outcomes. Data were collected from participants via smartphones with audio computer-assisted self-interviewing and included sociodemographic, behavioral, and psychological measures. Behavioral and psychological outcomes were measured using the Strengths and Difficulties Questionnaire (SDQ), Center for Epidemiological Studies Depression Scale for Children, and Revised Children's Manifest Anxiety Scale. Resilience was measured using the Connor-Davidson Resilience Scale. Adolescents living with HIV, residing with parents or caregivers living with HIV, or orphaned were defined as potentially vulnerable. Differences in behavioral and psychosocial outcomes based on median-split resilience scores were evaluated using SPSS Statistics 22 software.
**Results:** Of the 195 adolescents surveyed, 82 were identified as potentially vulnerable. Among these adolescents, those with higher resilience scores reported significantly lower behavioral problems using the total SDQ score (p< 0.009) with a mean score difference of 2.76 (SE: 1.02). On SDQ sub-scales, vulnerable but resilient adolescents reported less conduct problems (p< 0.006), less hyperactivity/inattention (p< 0.022), and less peer relationship problems (p< 0.03). There were no significant differences on depression, anxiety, or emotional symptoms. While the 113 adolescents identified as non-vulnerable presented significant differences between those with high and low resilience scores on total SDQ scores (p< 0.038), none of the SDQ sub-scales were significantly different.
**Conclusions:** The differences in psychosocial outcomes based on levels of resiliency can provide guidance into new approaches for HIV prevention, care, and support. Findings indicate promising directions for resilience-focused adolescent interventions to strengthen psychosocial well-being among adolescents infected and affected by HIV.

## TUPED256

### ABILITY AND WILLINGNESS TO CARE FOR CHILDREN IN A MATURE HIV EPIDEMIC: STREET-INVOLVED CHILDREN, FOSTERING ATTITUDES AND THE CONSEQUENCES OF HIV AMONG KENYAN FAMILIES

M. Goodman[1], M. Mutambudzi[2], S. Gitari[3], P. Keiser[1], S. Seidel[4]
*[1]University of Texas Medical Branch, Internal Medicine, Galveston, United States, [2]University of Texas Medical Branch, Preventive Medicine and Community Health, Galveston, United States, [3]Maua Methodist Hospital, Maua, Kenya, [4]University of Texas School of Public Health, Austin, United States*
*Presenting author email: migoodma@utmb.edu*

**Background:** Within Kenya, an estimated quarter of a million children live on the streets, and 1.8 million children are orphaned. In this study, we analyze how HIV contributes to the phenomenon of child-homelessness, and ask whether mothers in HIV-affected households are willing to provide care for children in need of a caretaker.
**Methods:** We interviewed a random community-sample of caregiving women (n=1974) in Meru County, Kenya using a structured questionnaire in summer 2015. Items included reported HIV prevalence of respondent and her partner, family functioning, social support, overall health and three outcomes - whether the respondent's has a child currently living on the streets, and whether the respondent was very willing to foster two designations of children - those biologically-related and those currently living on the streets.
**Results:** Controlling for alcohol use, education, wealth, age and household size, we found a positive graded association between the number of partners reported HIV+ and the probability that a child lives on the street, and an inverse graded association between number of reported HIV+ partners and willingness to foster children in need. Social support and overall health mediated only 10% of the association between living in an HIV-affected household and children migrating to the streets. Support, overall health and family functioning mediated 30% to 50% of the association between HIV-affected households and willingness to foster.
**Conclusions:** Reported child homelessness is strongly associated with household HIV, but the small percentage of mediated effect presents a greater need to focus on interactions between household and community factors in the context of HIV. HIV+ women are willing to foster, identifying them as potential assets in efforts to protect children - even more so with better social support, overall health and family functioning.

## TUPED257

### YOUNG PEOPLE LEAD ALL THE WAY: EVIDENCED-BASED ADVOCACY IS THE WAY!

S. Jiwan[1], N. Niwagaba[2]
*[1]Global Network of People Living with HIV, Communitty Mobilisation, Cape Town, South Africa, [2]Uganda Network of Young People Living with HIV & AIDS (UNYPA), Kampala, Uganda*

**Background:** With support from Stop AIDS NOW and GNP+, Uganda Network of People Living with HIV/AIDS (UNYPA) and Uganda Young Positives (UYP) undertook a 3-year Access, Service and Knowledge (ASK) Project for Young People Living with HIV (YPLHIV). We were supported to conduct PHDP research and use the results to improve knowledge, policies and programmes of YPLHIV.
The aim of the programme was to implement an evidence based advocacy programme that focused on Improving meaningful participation of YPLHIV in policy

development and HIV response by increasing awareness, knowledge and capacity, increasing respect of human rights, reducing stigma and discrimination and improving SRH services.
**Methods:** A qualitative approach was applied to this research, 275 youth, were interviewed, using a structured questionnaire. The youth were selected using non-random sampling techniques from the districts of Gulu and Iganga. The results of the data collected from the PHDP research were used to better advocate for SRH services. YPLHIV were at the center of the program from development to evaluation. Advocacy tools such as position papers, social media etc were used. Routine data was collected for health facilities to measure progress.
**Results:** Organized advocacy meetings with parliamentarians and youth groups, used the platform to share advocacy messages developed by the young people. Organized campaigns to promote affordability, availability and accessibility of quality SRH services targeting service providers and policy makers and on Ending through a beauty pageant. Training of YPLHIV on policies, laws, type of rights for YPLHIV, human rights violations and protection, and access to human rights and legal services in Partnership with UGANET. Supported young people to hold their leaders accountable through training, mentorship and strategic advice. Worked with local health facilities in 3 districts in promoting and strengthening YFS services.
**Conclusions:** When advocacy is guided by evidence, it becomes a simple-walk-through, a venture difficult to challenge and people being targeted with the advocacy messages indeed see seriousness in the whole process. Through our PHDP research we have been able to advocate based on evidence and see results from our work.

## TUPED258

### MIXED-METHODS RANDOMISED CONTROLLED TRIAL OF AN INTERVENTION TO IMPROVE THE PATIENT-CENTREDNESS OF CARE FOR PEOPLE ON ART IN SOUTH AFRICA: PATIENT-REPORTED OUTCOMES AND IMPLICATIONS FOR METHODS AND ROUTINE PRACTICE

R. Harding[1], L. Selman[1], L. Gwyther[2], L. Ganca[2], L. Sherr[3], V. Simms[4], I. Higgonson[1], W. Gao[1]
*[1]King's College London, Cicely Saunders Institute, London, United Kingdom, [2]University of Cape Town, Family Medicine, Cape Town, South Africa, [3]University College London, Infection & Population Health, London, United Kingdom, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom*
*Presenting author email: richard.harding@kcl.ac.uk*

**Background:** People living with HIV in Africa self-report their greatest burden is for psychosocial and information needs. 20x20x20 policy requires greater numbers of individuals to be maintained in care, and evidence is needed of simple models to meet needs.
**Methods:** An RCT aimed to determine the effectiveness of a brief intervention of training (2 week duration) of ART primary care clinic staff in person-centred assessment and a simple care plan, compared to standard care. Data were collected at 5monthly timepoints on three validated measures: POS (multidimensional measure of social, psychological, physical and spiritual problems), GHQ (psychiatric morbidity) and MOS-HIV (mental and physical quality of life). Data were analysed using GLAMM for multilevel modelling of ordinal longitudinal data. Qualitative data were collected.
**Results:** N=124 randomised, analysis conducted on n=59 control and n=57 intervention patients. Within-group significant improvements were found for all outcomes. Patients reported significant improvements on the POS in the intervention compared to control group (0.78, 95% CI 0.36-1.21, p< 0.001). Item analysis revealed change was for "Help and advice to plan for the future". No significant difference found for other measures. In qualitative data, control condition participants reported "*Being in the study has helped me a lot....That money goes a long way. Also talking to you helps.... you were listening.*" Another control patient said "*That is what I needed. I needed a friendly smile, a friendly person, a family and you were friendly, you were open, you were free.*"
**Conclusions:** This trial offers important data to inform routine care and future trial design. Firstly, simple training of existing ART nurses achieved improvement in patient-reported help and advice to plan. Second, the teaching of simple communication skills (especially listening) to staff may achieve important and meaningful outcomes for patients. Third, for future trial design to evaluate non-medical self-report outcomes our novel evidence indicates that:
a) Even modest participation expenses can provide important psychosocial improvements;
b) in the context of discrimination and social isolation associated with HIV, the impact of patient-reported outcome measures can be significant;
c) in high volume clinic settings, time taken to express problems can be extremely beneficial.

## TUPED259

### SOCIAL-SUPPORT FOR ADOLESCENTS LIVING WITH HIV IN SOUTH AFRICA: IMPROVING ACCESS AND GAINING INSIGHTS INTO NEEDS AND BEST PRACTICES

J.L. Koen[1], A. Kydd[2], Z. Figerova[2], M. Ngobeni[1], T. Konkobe[1]
*[1]SHM Foundation (South Africa), Project Khuluma, Sandton, South Africa, [2]The SHM Foundation (UK), London, United Kingdom*
*Presenting author email: jennifer.koen@gmail.com*

**Background:** Social-support is recognised as a critical component in addressing the HIV/AIDS crisis in adolescents. Adequate social-support is associated with better health outcomes and treatment compliance. However, adolescents living with HIV/AIDS (ALWHA) often have fragmented family-structures and fail to access treatment because of pragmatic challenges and fears of stigma. Social-support helps reduce stigma, but stigma hampers access to support when it is available. Also, to be effective, social-support must respond to recipients' needs.
**Description:** Project Khuluma aims to enhance access to psychosocial-support for ALWHA in South Africa. Peer-led support to groups of 10-15 ALWHA are run via text-message for 3 months at a time. To date, 99 ALWHAs have participated in Khuluma. Pre-and post levels of social-support were measured using the Multidimensional Measure of Perceived Social-Support. Text-message conversations were thematically analysed to gain further insights into social-support needs.
**Lessons learned:** Preliminary evaluation indicates a significant increase in perceived levels of social-support after participation and a significant decrease in internalised stigma. Allowing adolescents to shape the support they receive through peer-to-peer conversations provides unique insight into challenges and best practices in support access and delivery. There need for ongoing social-support is huge. Most of the 40000 text-messages sent were social-support related. Many described feelings of loneliness and isolation. Through Khuluma adolescents accessed and offered one-another informational and emotional-support. Participants discussed challenges navigating relationships with others, and concerns about disclosure. But described feeling a 'sense-of-belonging' through participating in a group, where they could talk candidly about their condition. Text-message-based communication is a preference among adolescents, and this likely contributed to high uptake.
**Conclusions/Next steps:** Khuluma helps ALWHAs build stronger networks of social-support with others facing similar struggles, and overcomes many barriers to accessing and providing social-support. Findings are positive and we aim to scale-up. Insights into the support needs of ALWHAs could also be valuable to policy-makers and programme-designers.

## TUPED260

### PSYCHOLOGICAL AND SOCIAL SUPPORT OF MSM LIVING WITH HIV, IN A HOSTILE ENVIRONMENT: RELEVANCE AND CHALLENGES

J. Ntetmen Mbetbo, H.C.D. Ngo Ndaptie, Z. Makong
*Alternatives Cameroon, Psychosocial Unit, Douala, Cameroon*
*Presenting author email: jdeflore@yahoo.fr*

**Background:** Since 2008, the Access Centre of Douala in Cameroon strives to offer to MSM living with HIV, health care free of any stigma. These people face several obstacles related to the double stigma of which they are victims, in a context that is particularly hostile to them. It therefore seemed clear from the start that the only medical care and follow-up would not be enough.
**Description:** The Access Centre is well structured into four autonomous yet interdependent Units : Human Rights Unit, Prevention Unit, Medical Unit and Psychological and Social Unit. The latter has developed activities related to the well-being of the beneficiaries of the Centre, including counseling, psychological consultations, positive life workshops, support groups, and vulnerability assessment. A diversified staff has been set up including psychosocial counselors, a social worker, psychologist, and therapeutic education specialists.
**Lessons learned:** The need of psycho-social support among MSM is more and more strong, more so than for medical consultations. In 2015, 400 medical consultations were given, against 1850 psycho-social support sessions. From around 30 beneficiaries of psycho-social support in 2008, we got 650 beneficiaries in 2015, including 313 HIV-positive MSM. Psycho-social support has opened the Center to other people and other problems out of HIV. This helped helped to de-stigmatize the Centre. There were 121 people from other population who received support in 2015, among which 67 HIV-positive.
Psycho-social support helps improve the state of the MSM living with HIV. The median CD4 count of patients followed MSM has been increasing. In 2011, it was 386/ $mm^3$ , 388 in 2012, 401 in 2013, and 433 in 2014.
The differentiation of the Units at Access Centre has helped the Psychological and social Unit to unfold fully, while integrating care has allowed beneficiaries to get a global and efficient care. Many view psycho-social personnel as their last resort in a homophobic environment.

Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

**Conclusions/Next steps:** Since the need of psychosocial support among MSM is increasingly strong, it is necessary to strengthen the staff and skills, and gradually make the staff professional. In this sense it is necessary to look for certified training, and better organize the body of psychosocial support professionals.

## ADAPTATION TO LIVING WITH HIV FOR INDIVIDUALS, FAMILIES AND COMMUNITIES

### TUPED261

### FACILITATORS OF AND BARRIERS TO HIV SELF-MANAGEMENT: PERSPECTIVES OF HIV-POSITIVE WOMEN IN CHINA

W.-T. Chen
*Yale University, School of Nursing, Orange, United States*
*Presenting author email: wei-ti.chen@yale.edu*

**Background:** In China, heterosexual sex is currently the most common transmission route for HIV. Many infected women belong to the high-risk category of commercial sex workers, but a significant number are housewives or career women who have been infected by their husbands. At least one third of sexually active men who have sex with men in China are married, so a woman might be married to a high-risk partner without realizing the need to take precautions against HIV/AIDS. China currently faces an HIV/AIDS crisis in which increasing numbers of HIV-positive individuals will need antiretroviral therapy and psychosocial support to cope with the diagnosis and ongoing treatment. Little is known about self-management among HIV-positive Chinese women in China. Understanding the experiences of this population is needed to promote self-management. This study aim is to explore perceived facilitators of and barriers to HIV self-management for HIV-positive Chinese women.
**Methods:** 27 in-depth interviews with HIV-positive women were conducted in Beijing and Shanghai. We recruited women who were diagnosed with HIV aged 18 years and above without significant cognitive problems who were receiving care at one the two hospitals above, either inpatient or outpatient. To be eligible for the study, the women had to be willing to share their personal experiences with us.
**Results:** Facilitators included families being supportive after disclosure, patients learning how to live with HIV, antiretroviral therapy (ART) adherence, and rediscovering the meaning of life. Several barriers were also identified, including lack of support, stigma, fatigue, and financial difficulty. HIV disclosure is essential to obtaining necessary support. Ironically, disclosing to family members who stigmatize the disease may invite unwelcome responses. Helping HIV-positive women to decrease self-stigma and develop an effective way to disclose, if they choose to, is important.
**Conclusions:** To break the isolation of HIV-positive women in China, future interventions should focus on disclosure strategies, tailoring them to enhance social support and decrease self-stigma. This study provides valuable information for the development of HIV-related self-management interventions in China, especially for HIV-positive women. The study also has implications for programs that are tailored to populations in similar sociocultural circumstances.

### TUPED262

### INTERVENTION FOR SERVICE PROVIDERS TO SUPPORT MATERNAL HIV DISCLOSURE IN THAILAND

S.J. Lee[1], L. Li[1], B. Nasungnoen[2], C. Lin[1]
*[1]University of California, Psychiatry and Biobehavioral Sciences, Los Angeles, United States, [2]Thai Ministry of Public Health, Nakhon Ratchasima Provincial Health Office, Nakhon Ratchasima, Thailand*
*Presenting author email: lincq@ucla.edu*

**Background:** With the advent of antiretroviral therapy, Mothers Living with HIV (MLH) in Thailand are living longer. One of the main challenges facing MLH is on their decisions on whether, why, and how they disclose their HIV status to their HIV-negative children. Service providers in Thailand can play a critical role in supporting MLH around their disclosure decisions.
The goal of this study was to develop and implement an intervention for service providers to assist MLH with their HIV disclosure to children in Northeastern Thailand.
**Methods:** In Phase 1, we explored the barriers around HIV disclosure to children through in-depth interviews with 10 service providers and 30 MLH. In Phase 2, we developed the intervention for service providers via focus groups with 20 MLH and 10 service providers. In Phase 3, we implemented the intervention with 40 service providers over 3 weeks.
**Results:** Phase 1 in-depth interviews revealed various factors influencing MLH's HIV disclosure to children, including fear of privacy breach, self-blame, communication difficulties, fear of rejection. In Phase 2, for each of the barriers identified from Phase 1, the intervention content consisted of the following components: assessment of readiness for HIV disclosure, examination of the risks and benefits of HIV disclosure, and skills-building sessions to assist PLH with step by step behavioral practice around HIV disclosure. In the Phase 3 intervention pilot, 40 service providers participated in the 3-week intervention. At their 3-month follow-up meeting, service providers reported interacting with 106 MLH. Service providers reported having improved confidence and skills to better assist their MLH patients around HIV disclosure to their children. Service providers reported about 60% of MLH disclosed their HIV status (62 MLH) to their children aged 7-17 years. The majority of MLH reported improved interaction with their children after disclosure, 97% reporting having no regrets about disclosing their status to children.
**Conclusions:** Our intervention pilot provided evidence for the next research phase of scaling up the intervention for service providers to better assist MLH around their HIV disclosure to children. We are currently developing strategies to integrate the intervention into the existing practice in the district hospitals.

### TUPED263

### A DESCRIPTIVE PROFILE OF PRIMARY CAREGIVERS OF HIV-INFECTED CHILDREN IN THE WESTERN CAPE, SOUTH AFRICA

N. Jooste[1], B. Laughton[2], E.F.M. Dobbels[2], P. Zuidewind[2], K.S. van Wyhe[2,3], M.J. Boivin[3], M.F. Cotton[2], C. Pretorius[1]
*[1]Stellenbosch University, Department of Psychology, Cape Town, South Africa, [2]Family Clinical Research Unit, Stellenbosch University and Tygerberg Children's Hospital, Department of Paediatrics and Child Health, Cape Town, South Africa, [3]Michigan State University, Department of Psychiatry and of Neurology & Ophthalmology, Ann Arbor, United States*

**Background:** Antiretroviral therapy rollout in South Africa allows HIV+ people to live significantly longer. The growing number of HIV+ children increases the burden on society to provide primary caregivers, who have a demanding and time-consuming responsibility to provide quality care to these children. The purpose of the study was to create a descriptive profile of primary caregivers of HIV+ children in the Western Cape.
**Methods:** This cross-sectional study utilised data from a Caregiver Health Questionnaire (CHQ) completed by medical doctors during consultation with primary caregivers of 7-year-old HIV+ children. The CHQ provides background information and insight into the caregiver's mental and physical health status, financial and social support, and any influence on the child's adherence to ARVs. These children were on a follow-on study of the Children with HIV early antiretroviral (CHER) trial in the Family Clinical Research Unit, Tygerberg Hospital, South Africa. An adherence counsellor assisted with translations where necessary. Descriptive statistics were used to generate a profile of the caregivers. The biopsychosocial model served as the theoretical framework.
**Results:** The 79 caregivers in the study were all female, mean age of 35.1 years (range 23-55). The majority were Black Africans (84.8%), biological mothers (82.3%) and unemployed (59.5%). Only 26 (32.9%) biological fathers were living with the child. The HIV-infected children's average age was 7.45 years, 54.4% were girls. The children's WHO HIV disease stage was stage 4 in 49.4% and stage 3 in 40.5%. Information on the caregivers is summarised in Table 1.
**Conclusions:** The caregivers are generally young, Black African females and the biological mothers of the HIV-infected children. The majority were HIV+, unemployed and lacked financial stability. The fathers were primarily absent and not supportive. Our data suggest a need for support on several levels to assist the caregivers in performing their caring role of HIV+ children.

| Characteristic | Frequency (%) | Characteristic | Frequency (%) |
|---|---|---|---|
| Female | 79 (100%) | Other physical illness present | 21 (26,6%) |
| Black African | 67 (84,8%) | Education grade 10 or less | 64 (81,0%) |
| Biological mother of HIV+ child | 65 (82,3%) | Employed | 32 (40,5%) |
| HIV-positive | 70 (88,6%) | Monthly household income <R2000 | 39 (49,4%) |
| HIV status disclosed to family | 73 (92,4%) | Sense of sufficient social support | 40 (50,6%) |

*[Characteristics of caregivers (N = 79)]*

## TUPED264

### ALLEVIATING STRESS AND IMPROVING FAMILY FUNCTIONING: RESULTS FROM A PRELIMINARY RCT OF A COUNSELING INTERVENTION FOR PARENTAL HIV DISCLOSURE IN CHINA

J.P. Yang[1], J.M. Simoni[1], C.-S. Shiu[2], W.-T. Chen[3], H. Lu[4]
*[1]University of Washington, Department of Psychology, Seattle, United States, [2]University of Washington, Seattle, United States, [3]Yale University, Orange, United States, [4]Shanghai Public Health Clinical Center, Shanghai, China*
*Presenting author email: jsimoni@uw.edu*

**Background:** One of the greatest challenges for parents who are living with HIV/AIDS is the decision-making process of whether, when, and how to disclose their HIV status to their children. Parents around the world report significant disclosure related distress such as fear of stigma, discrimination and possible rejection, uncertainty about how to disclose, and anxiety about negative psychological consequences for the child. HIV-positive parents in China have a particularly difficult time navigating this decision, as it is a setting with acute HIV stigma, limited mental health resources, as well as strong prescribed familial roles and responsibilities. Research is needed on interventions to support parents through this difficult process.
**Methods:** 40 HIV-positive outpatients with at least one child (13-25 years old) who was unaware of the parent's HIV diagnosis were enrolled in this trial at Shanghai Public Health Clinical Center. Participants were randomized to intervention or treatment-as-usual (TAU) arms with blind assessment. The intervention condition received three, hour-long, individual sessions over 4 weeks, which covered assessment, discussion of advantages and disadvantages to disclosure, psychoeducation about developmental appropriateness for children, psychoeducation about a continuum of disclosure behaviors ranging from no disclosure to full disclosure and open communication about HIV, and disclosure planning and practicing via role-plays.
**Results:** Primary disclosure related outcomes for intervention versus TAU were self-reported disclosure distress, self-efficacy, and disclosure behaviors. Secondary outcomes were parent child communication and family functioning. Cross-sectional (Wald tests) and longitudinal (general estimating equations) analyses at post intervention (4 weeks) and follow-up (13 weeks) demonstrated effects in the hypothesized directions of improved efficacy, behaviors, communication, and functioning, as well as decreased sitress.
**Conclusions:** Our results suggest that nurses are able to deliver a counseling intervention for parents living with HIV in China, with the potential to alleviate parental distress related to HIV disclosure to their children as well as improve family functioning. These promising results for a brief intervention integrated into a primary HIV care clinic setting warrants future trials powered for efficacy.

## TUPED265

### FAMILIES AFFECTED BY HIV/AIDS: CAREGIVERS' AND CHILDREN'S RESILIENCE AND CHILDREN'S DAILY CORTISOL OUTPUT

L. Chen[1], X. Li[2], D. Lin[1], J. Zhao[3], G. Zhao[3]
*[1]Institute of Developmental Psychology, Beijing Normal University, Beijing, China, [2]University of South Carolina, Department of Health Promotion, Education, and Behavior, Columbia, United States, [3]Institute of Behavior and Psychology, Henan University, Kaifeng, China*

**Background:** Caregivers (with or without HIV infection) for children affected by HIV/AIDS may have to face various challenges during their parenting practice. They may have to cope with their own or other adult family members' disease issues, as well as with psychological problems such as emotional difficulties or concerns towards the future of children. However, some of them show capacities (i.e. resilience) to adapt in the face of trauma and stress and even assist other family members to achieve better adjustments. This study's objective was to examine the effect of caregivers' resilience on children's health-relevant biomarker (daily cortisol output), as well as the mediating role of children's own resilience in such an effect.
**Methods:** Using a structured survey, quantitative data were collected from a total of 645 (8-15 years old) children affected by HIV and their primary caregivers (parental or non-parental) in a rural county of central China. Children also provided multiple saliva samples daily (waking, 30 minutes after waking, late afternoon and bedtime) for three consecutive days to assess their total cortisol output over the days. Caregivers' and children's resilience was assessed via self-report using adapted Connor-Davidson Resilience Scale (CD-RISC).
**Results:** Children with higher resilience showed higher cortisol levels at awakening and higher total cortisol output over the day (area under the curve with respect to ground, $AUC_G$). Caregivers' resilience was positively associated with children's cortisol levels at awakening and total cortisol output. Beside the direct effect, we also found evidence for an indirect effect of caregivers' resilience on children's wakeup cortisol level and daytime total cortisol output through higher children's resilience.
**Conclusions:** This work has implications for studying physiological functions among children affected by HIV/AIDS, and also suggests a pathway by which caregivers' resilience influences children's physiological functions and physical health. The capacities to adapt in the face of trauma and stress in HIV-affected families may be developed among both caregivers and their children.

# EXPERIENCES AND IMPACTS OF ANTIRETROVIRAL THERAPY

## TUPED266

### BARRIERS TO AND FACILITATORS OF ANTIRETROVIRAL THERAPY (ART) ENGAGEMENT AMONG ADULT GHANAIAN MEN WHO HAVE SEX WITH MEN (MSM) LIVING WITH HIV

A. Ogunbajo[1], T. Kershaw[1], F. Boakye[2], N.D. Wallace-Atiapah[2], L. Nelson[3]
*[1]Yale School of Public Health, Social & Behavioral Sciences, New Haven, United States, [2]Priorities on Rights and Sexual Health, Accra, Ghana, [3]University of Rochester, Rochester, United States*
*Presenting author email: adedotun.ogunbajo@yale.edu*

**Background:** Antiretroviral therapy (ART) is highly effective for reducing HIV viral load, thereby allowing people living with HIV to live longer and reduce their risk of transmitting the virus. In Ghana, men who have sex with men (MSM) have HIV prevalence that is more than triple that of the general population. However, no research exists on factors that influence engagement in ART in this group. Consequently, this qualitative study examined the barriers and facilitators to ART engagement among adult Ghanaian MSM living with HIV.
**Methods:** In-depth, face-to-face interviews were conducted with 30 Ghanaian MSM living with HIV between May and July 2015.Participants were recruited through key informants and snowball sampling. All interviews were conducted in a private office at a local community based organization. Verbatim transcripts of the recorded sessions were read several times prior to developing a coding scheme.
All interviews were coded utilizing qualitative analysis software (NVIVO 10). Emergent barriers and facilitators were discussed with other authors and disagreements were discussed until consensus was reached.
**Results:** The average age of participants was 29.1 years (S.D. = 7.7) and more than half (N=16, 53%) self-identified as gay/homosexual. Participants described financial burden as the primary barrier to engagement in HIV medication regimen. They reported not having sufficient money to afford ART, food to take medicines with, transportation to health center, and other lab procedures (CD4 count and viral load) required for ART prescription. Other barriers that emerged included prior adverse side effects from ART, shortage of ART at pharmacies and uneasiness with being seen at an HIV-related health facility. Facilitators of ART engagement included perceived effectiveness and benefits of ART, fear of public manifestations of HIV symptoms, and social support from friends and family.
**Conclusions:** This study identified financial difficulties as the most common barrier to ART engagement. This finding highlights the need for more cost-effective strategies to make ART and other auxiliary expenses such as food and transportation to medical facilities affordable for Ghanaian MSM. This might help prolong the lives of those affected by HIV and reduce their risk of infecting others.

## TUPED267

### "I TOLD HER THIS IS YOUR LIFE": HOW PRIMARY PARTNERS HELP OVERCOME BARRIERS RELATED TO ART ADHERENCE IN SOUTH AFRICA

A. Conroy[1], A. Leddy[2], M. Johnson[1], T. Ngubane[3], H. van Rooyen[3], L. Darbes[1]
*[1]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [2]John Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [3]Human Sciences Research Council, Social, Behavioural and Biomedical Interventions Unit, Msunduzi, South Africa*
*Presenting author email: amy.conroy@ucsf.edu*

**Background:** While South Africa's ART program is one of the largest in the world, many structural and psychosocial factors prevent HIV-positive individuals from achieving optimal adherence. Social relationships can help HIV-positive individuals overcome barriers to HIV care and treatment; however, little is known about the ways in which primary partners may affect each other's adherence to ART in South Africa. We qualitatively explored how relationship factors and partner support influence adherence to ART within heterosexual couples from rural KwaZulu-Natal, South Africa.
**Methods:** Twenty-four adult heterosexual couples (48 individuals) with at least one HIV-positive partner were recruited from local healthcare sites using maximum variation sampling. HIV-positive partners were sampled based by gender and length

of time on ART. Semi-structured interviews were conducted separately, but simultaneously, with each partner between November 2014 and March 2015. Topics discussed included: relationship history and future aspirations, relationship dynamics, intimate partner violence, experiences with HIV care and treatment (i.e., adherence, barriers to care and treatment), and HIV-related social support. Data were analyzed using an iterative thematic approach in Dedoose.

**Results:** The majority of couples were concordant HIV-positive (92%) and both on ART (63%). Barriers to ART adherence included: lack of transport and money to travel to clinics, limited nutritious food options, incarceration, alcohol consumption, inability to pick up ARTs because of work or travel, and service delivery issues at ART clinics. Participants described how primary partners helped them overcome these barriers through the provision of instrumental, informational, and emotional support. Forms of instrumental support included: providing transport or money to travel to the clinic, money for food, assistance preparing and purchasing healthy food; reminding a partner to take pills and attend appointments; and picking up pills. Informational support included: encouraging partners to stop drinking alcohol, eat healthy food, and adhere to medication. Emotional support included: providing love, comfort, and reassurance of one's commitment to the relationship.

**Conclusions:** Findings reveal that primary partners are important pillars of support for ART adherence, especially in a context of high unemployment and poverty. Future interventions that encourage and leverage these supportive relationships could improve ART adherence among heterosexual couples in similar settings.

## TUPED268

### The crucial role of the family context: family functioning and depression in HIV patients on public-sector ART in South Africa

E. Wouters[1,2], C. Masquillier[3], F.L.R. Booysen[4]

*[1]University of Antwerp, CELLO, Dept. of Sociology, Antwerp, Belgium, [2]University of the Free State, CHSR&D, Bloemfontein, South Africa, [3]University of Antwerp, Antwerpen, Belgium, [4]University of the Free State, Bloemfontein, South Africa*

*Presenting author email: caroline.masquillier@uantwerpen.be*

**Background:** As a chronic illness, HIV/AIDS requires life-long treatment adherence and retention - and thus sufficient attention to the psychosocial dimensions of chronic disease care in order to produce favourable antiretroviral treatment (ART) outcomes in a sustainable manner. Given the high prevalence of depression in chronic HIV patients, there is a clear need for further research into the determinants of depression in this population. In order to comprehensively study the predictors of depressive symptoms in HIV patients on ART, the socio-ecological theory postulates to not only incorporate the dominant individual-level and the more recent community-level approaches, but also incorporate the intermediate, but crucial family-level approach.

**Methods:** The present study aims to extend the current literature by simultaneously investigating the impact of a wide range individual-level, family-level and community-level determinants of depression in a sample of 435 patients enrolled in the Free State Province of South Africa public-sector ART program. Structural equation modeling is used to explore the relationships between both latent and manifest variables at two time points.

**Results:** Besides a number of individual-level correlates - namely education, internalized and external stigma, and avoidant and seeking social support coping styles - of depressive symptoms in HIV patients on ART, the study also revealed the important role of family functioning in predicting depression. While family attachment emerged as the only factor to continuously and negatively impact depression at both time points, the second dimension of family functioning, changeability, was the only factor to produce a negative cross-lagged effect on depression.

**Conclusions:** The immediate and long-term impact of family functioning on depression draws attention to the role of family dynamics in the mental health of people living with HIV/AIDS. In addition to individual-level and community-based factors, future research activities should also incorporate the role of the family context in research into the mental health of HIV patients, as our results demonstrate that the familial context in which a person with HIV on ART resides is inextricably interconnected with his/her health outcomes.

## TUPED269

### Comparison of different self-reported ART adherence measures: a quantitative study in China

Z. Shen[1], S. Qiao[2], X. Li[2], Y. Zhou[1], Z. Tang[1], J. Zhao[3]

*[1]Guangxi CDC, AIDS/STD Prevention and Control, Nanning, China, [2]University of South Carolina, Columbia, United States, [3]Henan University, Kaifeng, United States*

*Presenting author email: shengzhiyong88@gmail.com*

**Background:** Antiretroviral treatment (ART) benefits HIV-infected persons by controlling virtual replications and reducing the likelihood of opportunistic infections. To obtain full benefits of ART, maintaining optimal levels of adherence is crucial for people living with HIV/AIDS (PLWH). Most studies have used subjective measures to assess adherence based on self-report of dosage in a certain time window. Various self-reported measures have been used but unclear how they are good in predicting clinical outcomes (CD4 counts, viral load). The current study aims to compare several self-reported ART adherence measures in terms of their associations with HIV clinical outcomes.

**Methods:** A total of 2,987 PLWH was recruited from 12 cities/counties in Guangxi, China to participate in a cross-sectional survey on health condition. Participants who received ART (n=2,050) were asked about medicine adherence issues. The ART adherence measures include dosages missed in past 3 days, days of taking medicine as prescribed in past 1 month, days of not taking medicine as prescribed in past 1 month; whether or not miss a dosage, the frequency of missing a dosage, and whether or not miss a dosage in past weekend. Correlation test and linear regression models were used for continuous adherence measures and one-way ANOVA and GLM were employed for categorical measures.

**Results:** Controlling basic demographics, CD4 counts were significantly associated with dosage missed in past 3 days (aβ=-.092, p< .0001), days of taking ART as prescribed in past 1 month (aβ=.084, p< .0001), and days of not taking ART as prescribed in past 1 month (aβ=-.046, p=.041). GLM results suggest that CD4 counts was significantly associated with whether or not miss a dosage (F=4.544, p=.033), frequency of missing a dosage (F=4.399, p=.013), and whether or not miss a dosage in past weekend (F=3.259, p=.039). Only dosage missed in past 3 days was significantly related to virus loading level (F=7.761, p< .0001).

**Conclusions:** Self-reported measure is useful to assess ART adherence because of its significant association with clinical outcomes among PLWH. However, measures with various recall windows and expressions differ in magnitude of the relations to clinical outcomes, which should be fully considered in selecting measurement in future.

## TUPED270

### Results of the Sepo II study: experiences of HIV-related episodic disability among women and men on ART in Lusaka, Zambia

S. Nixon[1,2], V. Bond[3], P. Solomon[4], C. Carmeron[2], J. Hanass-Hancock[5], M. Maimbolwa[6], A. Menon[6], C. Mwamba[3], P. Simwaba[7], R. Sinyinza[7], M. Siwale[8], S. Tattle[9], T. Yates[9]

*[1]University of Toronto, Department of Physical Therapy, Toronto, Canada, [2]International Centre for Disability and Rehabilitation (ICDR), Toronto, Canada, [3]Zambart, Lusaka, Zambia, [4]McMaster University, Hamilton, Canada, [5]University of KwaZulu Natal, Durban, South Africa, [6]University of Zambia, Lusaka, Zambia, [7]Disability HIV & AIDS Trust, Lusaka, Zambia, [8]Lusaka Trust Hospital, Lusaka, Zambia, [9]Canadian Working Group on HIV and Rehabilitation, Toronto, Canada*

*Presenting author email: gbond@zambart.org.zm*

**Background:** The concept of "episodic disability" (i.e., fluctuations of wellness, illness and disablement) was developed in Canada to describe the experience of people living long-term with HIV since the advent of ART in the 2000's. Framing challenges in terms of "episodic disability" contributed to health care and employment policies in Canada. However, HIV-related episodic disability has not been explored in Sub-Saharan Africa despite increased access to ART in the region in the last decade. The objective of this study was to explore experiences of HIV-related episodic disability among women and men on ART in Lusaka, Zambia.

**Methods:** "Sepo II" is a qualitative longitudinal study involving three in-depth, semi-structured interviews approximately 6 months apart with participants from public and private health clinics in Lusaka, Zambia. Thirty-five participants were purposively recruited for variability by gender (17 men, 18 women), time on treatment (1-13 years), and socio-economic status. Interpretivist analysis was conducted on 98 in-depth interviews using the collaborative "DEPICT" method (Flicker & Nixon, 2013). The study was guided by the WHO "International Classification of Functioning, Disability and Health" (ICF), and O'Brien's "Episodic Disability Framework".

**Results:** Participants described diverse experiences of episodic disability across the three interview rounds. Greatest fluctuations were described in terms of "impairments" (e.g., fatigue, pain, memory challenges) and "participant restrictions" (e.g., shifting social roles), which are disablement concepts in the WHO ICF. Participants

frequently described multiple co-existing forms of disablement, of varying degrees of severity (from bothersome to extremely limiting), and which were improving, resolving or worsening in unique patterns. Despite these narratives of disablement, participants also consistently emphasized their gratitude for life-saving ART and, paradoxically, often described themselves as doing well.
**Conclusions:** This is the first study to describe the experience of episodic disability among women and men living with HIV in a Sub-Saharan African context. Findings point to the need for health and social service providers to consider the diverse challenges beyond the medical model that are faced by people on ART who may report "doing well". "Rehabilitation" and "disability" frameworks can help illuminate the episodic health- and life-related impacts of living longer with HIV.

## TUPED271

### Adherence with combination antiretroviral therapy (cART): do challenges still persist?

M. Murray[1], R. Hahn[2], B. Goodwin[3], S. Hogue[4], K. Davis[4]
*[1]ViiVHealthcare, Health Outcomes, Brentford, United Kingdom, [2]Nielsen, Rochester, United States, [3]GSK, Research Triangle Park, United States, [4]RTI Health Solutions, Research Triangle Park, United States*
*Presenting author email: miranda.i.murray@viivhealthcare.com*

**Background:** The primary goals of cART are to maximally suppress viral load, restore and preserve immune function, reduce morbidity and mortality, improve quality of life, and prevent HIV transmission. Adherence to cART continues to be a challenge in the treatment of HIV. Partial adherence can result in failure to maintain virologic suppression and permit the development of ARV resistance through viral mutation. This study focuses on the factors that drive adherence to cART and to determining their importance in choosing an cART regimen among patients and physicians.
**Methods:** In mid-2014, two cross-sectional Internet-based surveys were conducted in the US with 400 patients on cART and with 200 physicians who treat HIV. The online surveys were pretested with respondents prior to administration. The patient survey included assessments of quality of life, HIV treatment experience, medication side effects, adherence behaviors, treatment satisfaction, and interaction with health care providers. The physician survey addressed similar topics to allow for comparisons between HIV patients and physicians.
**Results:** The patient sample consisted of predominantly males (79.3%) with an average age of 41.1 (SD = 13.2) years. Sixty-one percent reported being homosexual, while 28.1% reported heterosexual, and 11.1% bisexual. The physician sample consisted of 119 primary care and 81 infectious disease specialists. Based on the adapted Morisky Medication Adherence Scale, 68.8% percent of participants self-reported as being adherent (score < 3) with their HIV medications. Physicians were more likely that patients (64.5% vs 13.7%) to cite side-effects as a reason for non-adherence. Availability and forgetting to take medication, feeling depressed and side effects were most commonly cited reasons by both groups (table 1).

| Top Reasons for Not Taking HIV Medications as Prescribed (Ranked by Patients) | Patients (%) | Physicians (%) |
|---|---|---|
| Forgetting to take | 36.2% | 67.5% |
| Not having pills available (e.g., away from home, on vacation) | 17.7% | 39.5% |
| Felt ill or sick | 15.9% | 45.5% |
| Change in daily schedule | 15.3% | 24.5% |
| Busy with other things | 14.9% | 34.5% |
| Feeling depressed/overwhelmed | 14.6% | 61.0% |
| Experienced side effects | 13.7% | 64.5% |
| Had difficulty taking medications at specific times | 13.2% | 33.0% |
| Did not want others to notice me taking my medication(s) | 12.9% | 26.0% |

*[Table 1. Comparison of Reasons for Non-Adherence According to HIV Patients and Physicians]*

**Conclusions:** Adherence challenges persist with cART for both physician and patients. HIV and its treatment has a substantial impact on patients' lives and many factors come into play in decision-making by both the patient and the physician.

## TUPED272

### "Sometimes you feel like you have no choice but to bear with it all": how much do we understand side-effects of ARVs on lives of women living with HIV?

A. Welbourn[1], L. Orza[2], S. Bewley[3], E.T. Crone[4], M. Vazquez[5]
*[1]Salamander Trust, London, United Kingdom, [2]Salamander Trust / ATHENA Network, London, United Kingdom, [3]Kings College, London University, Women's Health Academic Centre, London, United Kingdom, [4]ATHENA Network, Seattle, United States, [5]Salamander Trust, Barcelona, Spain*
*Presenting author email: alice@salamandertrust.net*

**Background:** WHO promotes far-reaching ARV coverage for prevention and treatment of HIV, yet little is known about long-term adherence to ARVs and their effects in relation to physical, sexual, psychological or other dimensions of women's lives. The aim of this study was to examine ARV side-effects in women living with HIV.
**Methods:** A global online values and preferences survey was commissioned by WHO. It was informed and shaped by a Global Reference Group of 14 women living with HIV and included an optional section on HIV treatment and side-effects . The survey contained a mix of closed questions (quantitative analysis) and free text responses (qualitative analysis).
**Results:** Of 832 women aged 15-72 from 94 countries who completed the online survey, 434 (52%) responded to the optional treatment section. Of these, 88% were on treatment. Only 11.9% reported no side-effects.
The mean number of different reported ARV side-effects was four including fatigue (64.8%), mood changes (47.1%), headaches (40.6%), body dysmorphia (40.2%), loss of libido (37.5%), strange dreams (29.9%), and menstrual disorders (24.1%). These affected women's ability to enjoy a healthy and satisfying sex life; to work; and to enjoy social activities. Singly or collectively, side-effects put strains on relationships, led to financial insecurity or poverty, and contributed to mental ill-health, including loneliness, isolation, stress, anxiety, and depression. Respondents reported limited information about side-effects, especially at treatment initiation, and felt that health providers did not take side-effects seriously. Regarding an undetectable viral load, some women expressed potential or actual reduced ability to negotiate condom use, to protect against STIs or pregnancy.
**Conclusions:** These findings have implications for treatment roll-out, warranting attention from policy makers and providers alike. Urgent research is required to understand: to what extent is it possible to adhere to medication which reduces quality of life, especially if women start ARVs when feeling well; how women's concerns about STIs and unplanned pregnancy can be addressed in the context of treatment *as* prevention; whether and how coercion and potential gender-based violence can be avoided in relation to ARV uptake; and the risks, benefits and safety of long-term medication use.

## TUPED273

### Eddies, backflows and stagnancy: qualitative research findings from Eastern and Southern Africa on the HIV treatment cascade and its 'goodness of fit'

M. Skovdal[1], A. Wringe[2], S. Bernays[2], J. Seeley[2], J. Renju[2,3], S. Paparini[2], J. Wamoyi[4], M. Moshabela[5], K. Church[2], O. Bonnington[2]
*[1]University of Copenhagen, Department of Public Health, Copenhagen, Denmark, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Kilimanjaro Christian Medical University College, Moshi, Tanzania, United Republic of, [4]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [5]University of KwaZulu-Natal, Durban, South Africa*
*Presenting author email: m.skovdal@sund.ku.dk*

**Background:** The HIV treatment cascade has become a guiding model for delivering medical HIV services, focusing on sequential steps, from the initial diagnosis of HIV through to viral suppression. Although commentators have recently argued that it fails to resonate with the complex and lived realities of people living with HIV, no previous multi-country qualitative study has interrogated the use-value of the HIV treatment cascade model - from the perspective of users and providers themselves - to develop recommendations for a second generation of HIV care continua frameworks.
**Methods:** Data is drawn from a multi-country study examining how people living with HIV (PLHIV), and their sociality, interact with the HIV treatment cascade. Studies took place in Uganda, South Africa, Tanzania, Kenya, Malawi and Zimbabwe and involved in-depth interviews with 180 HIV service users, 36 HIV service providers and 36 relatives of people known to have died from AIDS. Ethical clearance was obtained in each country. Data were coded in NVivo10 using inductive and deductive approaches to identify emerging themes.
**Results:** Findings reveal a mismatch between how PLHIV experience and engage with HIV care and the linearity assumed by the treatment cascade framework. PLHIV - across all sites - were observed to step in and out of HIV services in multiple and unpredictable ways, and levels of engagement were variable. This led to different forms of disruption to progression along the cascade, influenced by three

factors: i) contextual influences, including partner, family, and community relations, cultural norms and socio-economic circumstances; ii) quality of health services, including patient-provider relations and trust; and iii) individual agency, with some PLHIV being fed-up with taking drugs, and others seeking alternative services and starting over.
**Conclusions:** Biomedical HIV treatment trajectories do not resonate with the frequently unpredictable ways in which PLHIV interact with HIV services. 90-90-90 targets place an even narrower emphasis on the cascade and may inadvertently result in lost opportunities to support PLHIV who do not readily align their care-seeking to restrictive pathways. Second generation HIV care continua frameworks are needed that are more flexible and patient-centered, and recognize how sociality and agency interface with individual HIV care trajectories.

## TUPED274

### LOOKING AT ADHERENCE THROUGH A DISABILITY LENS

B.S. Carpenter[1], J. Hanass-Hancock[1], H. Myezwa[2]
*[1]University of KwaZulu Natal, Health Economics and HIV/AIDS Research Division (HEARD), Durban, South Africa, [2]University of the Witwatersrand, Department of Physiotherapy, Johannesburg, South Africa*
*Presenting author email: carpenter@ukzn.ac.za*

**Background:** Antiretroviral therapy (ART) has changed the lives and expectations of millions of people living with HIV. However, maintaining an undetectable viral load requires strict adherence to treatment. As current programmes targeting adherence begin to lose speed, the effects of co-morbidities and disabilities on adherence are increasingly being considered. While the effects of many co-morbidities have received substantial research interest, the impact of functional limitations/disabilities is seldom explored.
**Methods:** This paper draws on baseline cohort data of 1042 people on ART in a public healthcare setting in KwaZulu-Natal, South Africa. The study examined functional limitations/disability (WHODAS-2.0), depressive symptoms (CES-D10), HIV-related health symptoms, adherence (CASE index), livelihood (social, financial, physical/natural, and human capital), food security (U.S. Household Food Security Survey Module: Six-Item Short Form), and biomarkers such as CD4 and BMI. The analysis explored associations with missed treatment and included descriptive statistics, bivariate, and multivariate analyses.
**Results:** 83% of participants scored with perfect adherence (no missed/delayed treatments) and only 7% scored below the threshold for adequate adherence. Depressive symptoms and mobility limitations were experienced by 26% and 22% of participants respectively, and both were associated with worse adherence. 13% of participants experiencing mobility limitations were not adequately adherent, as compared to 6% in the rest of the population. Similarly, 13% of participants experiencing depressive symptoms were not adequately adherent, as compared to 5% in the rest of the population. Multivariate analyses controlling for age, gender, ARV duration, and exposure to shocks found that depressive symptoms and mobility impairments were the most significant predictors of inadequate adherence.
**Conclusions:** Given the current focus on treatment adherence within the Fast-Track strategy and the 90-90-90 goals, it is important to identify drivers of non-adherence. While mental health has previously been highlighted, this study suggests that disabilities may be just as important in achieving adherence. Given this finding, there is a need for further inclusion of rehabilitation services in the continuum of HIV care. Additionally, more rigorous research is needed to better understand the role of disability as a barrier to adherence and how rehabilitation can be used to mitigate this risk.

## TUPED275

### ARE HIV ANTIRETROVIRAL THERAPY PROGRAMMES POSITIVELY AFFECTING RISKY BEHAVIOUR AMONGST PATIENTS? A REVIEW OF THE SOUTH AFRICAN HIV INCIDENCE PROVINCIAL SURVEILLANCE SYSTEM (HIPSS) DATA

G. George[1], S. Beckett[1], K. Govender[1,2], A. Kharsany[3], C. Cawood[4], D. Khanyile[4], A. Grobler[3]
*[1]University of KwaZulu Natal, Health Economic and HIV/AIDS Research Division, Durban, South Africa, [2]University of KwaZulu Natal, Psychology, Durban, South Africa, [3]Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, [4]Epicentre AIDS Risk Management (Pty) Limited, Paarl, South Africa*
*Presenting author email: govenderk2@ukzn.ac.za*

**Background:** South Africa has the largest HIV treatment programme with >3,000,000 people accessing antiretroviral treatment (ART). Studies show that patients on ART present a lower risk of transmitting HIV to sexual partners. However, few studies have investigated the impact of exposure to HIV services, specifically, HIV counselling and testing and accessing health facilities, have on the risk behaviour of clients on ART.
**Methods:** The HIV Incidence Provincial Surveillance System (HIPSS) collected data in 2014-2015 from randomly selected individuals aged 15 to 49 years in 9554 households in the uMgungundlovu District in KwaZulu-Natal, South Africa. Adjusted odds ratios (aOR) were calculated by means of a logistic regression.
**Results:** In total, 3855 (40%) HIV positive participants were categorized into individuals on ART (40%); those who knew their status but were not on treatment (19%) and; those who did not know their status and were not on treatment (41%). The majority of respondents were female (75%) with the mean age of 33 years (SD = 8). Participants unaware of their status were more likely to use condoms inconsistently in the previous 12 months (83.1%) than those who knew their status but were not on ARVs (74.5%) and those who were on treatment (65.4%, $p < .001$), additionally, they were more likely to have more recent sexual partners ($p < .001$) than persons aware of their HIV positive status. After controlling for sex, age, marital status and socioeconomic status, HIV positive individuals on treatment were more than twice as likely than those unaware of their status to use condoms consistently: in the previous 12 months (aOR=2.642, $p < .001$), with their most recent partner (aOR=2.875, $p = .003$) and after consuming alcohol (aOR = 2.196, $p < .001$). Moreover, individuals on treatment were less likely to have consumed alcohol than those individuals who were not on treatment but knew their status (aOR= .522, $p < .001$).
**Conclusions:** The results highlight less risky sex and behaviour among persons on ART than those who are not. This could suggest that exposure to HIV services reduces risky behaviour and further affirms the importance of expanding testing and treatment coverage.

# GROWING UP WITH HIV: SPECIFIC NEEDS AND INTERVENTIONS FOR CHILDREN, ADOLESCENTS AND YOUTH

## TUPED276

### "BECAUSE THEY CARE": UNDERSTANDING PATHWAYS TO CLASSROOM CONCENTRATION PROBLEMS AMONG HIV-AFFECTED CHILDREN IN WESTERN KENYA

M. Skovdal
*University of Copenhagen, Department of Public Health, Copenhagen, Denmark*
*Presenting author email: m.skovdal@sund.ku.dk*

**Background:** Children and young people living in households affected by HIV are experiencing poorer educational outcomes compared to their peers. A number of interwoven factors - including patterns of parental loss, mental health, household poverty and young caregiving - have been identified as key influences on their educational attainment. This article explores how these forms of marginalisation interface and manifest themselves in classroom concentration problems, undermining their education.
**Methods:** This mixed qualitative methods study was conducted with teachers and pupils from three primary and three secondary schools in the Siaya county of Western Kenya. Specifically, it involved 18 teachers through individual interviews and 57 HIV-affected children and youth through an assessment questionnaire (n=57), individual interviews (n=47) and Photovoice (n=51). Verbatim transcripts were imported into NVivo 10 for thematic indexing and analysis.
**Results:** The analysis revealed three pathways to classroom concentration problems amongst HIV-affected pupils. One, in the context of household poverty and illness, a general 'lack of care' and neglect meant that many of the participating pupils went to school hungry, unable to follow classes. Others, through looking visibly poor, were teased by peers, and felt anxious when in school. Two, many participating pupils had their minds at home ('caring about'). They were concerned about sick or frail household members, thinking about their next meal and care needs. Some even worried about returning home to find their loved one deceased. Three, some HIV-affected pupils play a key role in keeping their household afloat, generating food and income as well as providing practical support. 'Caregiving' pupils often reported coming to school exhausted, with limited physical and mental energy left for learning.
**Conclusions:** Care, household poverty and familial HIV emerged as central to understanding the classroom concentration problems of HIV-affected pupils. Pupils' ethics of care, whether through 'caring about' or 'caregiving', not only demonstrate their profound sense of empathy and responsibility, but can, in a deprived context, have severe consequences for their education. These findings suggest that keeping HIV-affected children in school is only part of the solution. To ensure they learn, education initiatives must simultaneously alleviate household poverty and other challenges pertaining to familial HIV.

## TUPED277

### BUILDING BRIDGES BETWEEN COMMUNITIES, HOUSEHOLDS AND HEALTH FACILITIES TO ADDRESS BARRIERS TO PEDIATRIC HIV TREATMENT AND CARE

G. Nakazzi[1,2], M. Elang[3], V. Nsubuga[4], D. Bitira[5], S. Nganda[6], M. Musinguzi[7], K. Lorpenda[8]
*[1]Community Health Alliance Uganda, Communications and Community Engagements, Kampala, Uganda, [2]International Health Sciences University, Public Health, Kampala, Uganda, [3]Community Health Alliance Uganda, Health Programmes, Kampala, Uganda, [4]Community Health Alliance Uganda, Behaviorial Change Communications, Kampala, Uganda, [5]Community Health Alliance Uganda, Monitoring and Evaluation, Kampala, Uganda, [6]National Forum of People Living With HIV Networks in Uganda, Kampala, Uganda, [7]ICCO Cooperation, Central and Eastern Africa Regional Office, Kampala, Uganda, [8]International HIV/AIDS Alliance, Brighton, United Kingdom*
*Presenting author email: graciejnak@yahoo.com*

**Background:** Uganda hasan estimated 123,754 pregnant women living with HIV. Approximately 23% of themare not in HIV care and nor are their babies**.** Despite progress made against HIV, the treatment coverage for the 193, 500 children under 14is 31%. There is need to accelerate PMTCT to reduce the number of new HIV infections among infants and increase the number of HIV-positive children on treatment.
There is still ignorance around pediatric HIV, coupled with stigma and discrimination in communities, health facilities and households. Spouses are not disclosing their status to each other, fearing separation or domestic violence; this hinders early testing and ART initiation for children. Economic situations can also hinder them from accessing clinics.
**Description:** The TAFU project (Towards an AIDS Free Generation in Uganda) aims at reducing new HIV infections among infants and increasing the number of children on treatment in 2 districts in Uganda. The project builds bridges between communities, and health facilities, mobilizing communities to access HCT, treatment and adherence support, and creating awareness around pediatric HIV treatment and care for children.
The program has encouraged community ownership at district and community level; creating linkages and referrals from households to health facilities; forming child, peer and church support groups for adherence support. Implementation is through 45 Village health teams (VHTs) trained and mentored in pediatric HIV TAFU project achievements October- December 2015;
-366 children and pregnant women identified, referred and enrolled into ART care from216 household visits by VHTs;
-24 religious leaders trained on pediatric HIV to promote couple communication and fight stigma and discrimination in communities;
-100 households with children living with HIV linked to village loans and savings scheme for economic empowerment.
**Lessons learned:** Involvement of religious and local leaders in mobilization, community dialogues and open couple dialogues has reduced stigma and discrimination and increased uptake for pediatric HIV care and treatment.
**Conclusions/Next steps:** Access to pediatric HIV treatment requires a holistic approach from household to community and health facility. This will increase uptake of to treatment for children living with HIV.

## TUPED278

### HOW DO YOUNG PEOPLE LIVING WITH HIV FEEL ON ANTIRETROVIRAL THERAPY?: THE NEED TO ADDRESS SIDE-EFFECTS AND TREATMENT DISENGAGEMENT

S. Paparini[1], S. Bernays[1], J. Seeley[2,3], S. Namukwaya[3], and BREATHER Trial Team
*[1]London School of Hygiene and Tropical Medicine, Social and Environmental Health Research, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom, [3]MRC/UVRI Uganda Research Unit on AIDS, Social Science Programme, Entebbe, Uganda*
*Presenting author email: sarah.bernays@lshtm.ac.uk*

**Background:** Poor adherence and treatment disengagement are of great concern, especially among adolescents. Recent research with young people (YP) highlights a scarcity of opportunities to share their perspectives on the impact of HIV and antiretroviral therapy (ART) on their lives. In addition, their time in clinical care and on treatment significantly shape the meanings they attach to both HIV and ART. Yet there remains limited research about the psychosocial effects of treatment- and HIV- related symptoms on YP's health, well-being and adherence behaviours.
**Methods:** A longitudinal qualitative study embedded within a randomised controlled trial (BREATHER) testing the safety of a treatment interruption intervention (Short Cycle Therapy (SCT)). We repeatedly interviewed 43 YP throughout the trial (38% total YP; age 11-22 years, who knew their HIV diagnosis and gave additional consent) in UK/Ireland (7), USA (10) and Uganda (26).
Focus groups with 25 trial participants and interviews with 16 of their caregivers were also held in the Ugandan site at the end of the trial. The qualitative study explored YP's experiences of the BREATHER trial as well as broader issues of ART adherence.
**Results:** Treatment side-effects and physical symptoms were not a specific focus of our study, yet they emerge as central to how participants spoke about their condition. Views about pills and toxicity, fear of future illness (particularly from non-adherence), neuro-cognitive difficulties, anxiety and hunger, were all notable features of participants' narratives. Interviews with caregivers further suggest the centrality of the physical dimension of HIV and ART for the YP in their care (e.g. specific diets, weight gain or loss, drug toxicity, issues with concentration) and the way in which feelings about ART might affect YP's adherence.
**Conclusions:** The physical dimension of HIV and ART for YP living with HIV and particularly for adolescents, remains poorly understood. Further evidence, including our study findings, can help us illuminate how clinical understandings of HIV and ART interplay with community and personal narratives and how these might shape health and adherence behaviours. In the future, this may inform ways to engage and support YP in relation to how they feel about their health and bodies.

## TUPED279

### AN EVALUATION OF AN INTENSIVE RESIDENTIAL SUPPORT CAMP INTERVENTION FOR 12-16 YEAR OLDS LIVING WITH HIV IN THE UK

M. Evangeli[1], I. Lut[2], A. Ely[3]
*[1]Royal Holloway University of London, Psychology, Egham, United Kingdom, [2]Royal Holloway University of London, Egham, United Kingdom, [3]CHIVA, Bristol, United Kingdom*
*Presenting author email: michael.evangeli@rhul.ac.uk*

**Background:** Offering residential interventions for young people with HIV has the potential for enhancing well-being and increasing HIV-related knowledge. There is limited literature on evaluating residential interventions for young people living with HIV, with only qualitative methods used. This study evaluated a week-long intensive peer engagement residential support camp for 77 12-16 year olds living with HIV. The intervention consisted of individual emotional support provided by professional staff; participatory HIV knowledge and understanding workshops; and creative and performing arts workshops encouraging expression of experiences of growing up with HIV. Peer support was provided by older peers with HIV. The study evaluated whether there were any quantitative changes in psychological outcomes from pre to post-intervention.
**Methods:** A quantitative single group repeated measures design was used, with 67 participants
(87% response rate; 39 (58%) female; median age 15, IQR 13-15). Multi item self-report measures of HIV knowledge, antiretroviral (ART) adherence cognitions, HIV disclosure cognitions and affect, HIV communication cognitions and affect, HIV stigma, Quality of Life, general health and self-perception were administered immediately before and after the intervention.
**Results:** There were improvements in pro HIV disclosure cognitions and affect from pre-intervention (total scale score mean 56.60, sd 9.37) to post-intervention (mean 61.67, sd 9.17)(p< 0.001) and in pro HIV communication beliefs from pre-intervention (mean 25.63, sd 4.66) to post-intervention (mean 26.85, sd 4.92) (p=0.05). Positive changes were also seen in self-perception from pre-intervention (mean 18.50, sd 5.04) to post-intervention (mean 19.90, sd 4.09)(p=0.01) and HIV knowledge from pre-intervention (median 14, IQR 11-15.27) to post-intervention (median 15, IQR 13-17)(p< 0.001). There was little evidence of change in HIV stigma (p=0.79), Quality of Life (p=0.12), general health (p=0.79) or ART adherence cognitions (p=0.15).
**Conclusions:** Positive changes in important psychological outcomes were seen after a brief residential intervention. Changes in HIV disclosure cognitions and affect, and in HIV communication cognition and affect, in particular, have rarely been reported in the literature on psychosocial interventions in any HIV-positive populations. These outcomes are important in their own right but may also be mediators of change of behavioural outcomes such as increased HIV disclosure rates and reduced sexual risk behaviour.

## TUPED280

### UNDERSTANDING DISCLOSURE PROCESS AND NEED FOR PROGRAMMATIC INTERVENTIONS FOR ADOLESCENT LIVING WITH HIV IN GOA, INDIA

P.P. Ferrao, P. Borges
*Human Touch Velsao, Goa, India*
*Presenting author email: info@humantouch.org.in*

**Background:** With the increasing number of adolescents beginning to understand and cope with HIV through self-care, the disclosure process gains importance in the care and support programmes. Disclosure needs to be driven in a timely and correct manner, so as to help adolescents living with HIV to understand dating sexual relationships, paving way for an informed and healthy lifestyle.

**Methods:** In 2015, Human Touch initiated a qualitative study among adolescents aged 12-19 living with HIV in Goa, India, and with their parents and care providers. The study employed interviews and focus group discussions basically focusing on the disclosure of HIV status to ALHIV, their disclosure of status to their friends and partners and the impact of being disclosed and disclosure to others.

**Results:** Six main barriers were identified through the study: sex, still being considered a taboo, hinders parents from communicating with their children; fear of being stigmatized in school and community setting; parents not able to gauge the appropriate time to disclose and post disclosure concerns including well-being and treatment nonadherence.

With regard to disclosure of status to their partners and friends, fear of rejection and status being known to many, leading to more stigma were the main barriers identified. In some cases, programmes by NGOs offering psychosocial support helped adolescents come to terms with HIV diagnosis.

Common findings of disclosure identified were anxiety, depression, self-blame, fear of not being able to get married, have a family, not being able to pursue career ambitions, and not being accepted for higher education in professional courses. But some adolescents exposed to psychosocial support programmes of organizations shared of increased access to treatment and adherence and support in forming healthy relationships.

**Conclusions:** There is a need for specific interventions in the public health programmes for the government. The personnel need to be trained in handling this emerging challenge. Parents, teachers and care givers need to be trained to assess and understand the capacity and maturity of their adolescents and to determine the appropriate time for disclosure. Post disclosure, there should be access to ongoing support to prevent disclosure from negatively affecting their psychological and sexual wellbeing.

### EFFECTIVE ROLE SHARING FOR HEALTHY BODY MASS INDEX STATUS AMONG HIV-POSITIVE CHILDREN AND CAREGIVERS

K. Kikuchi[1], K. Poudel[2], J. Muganda[3], A. Majyambere[4], V. Mutabazi[4]
*[1]University of Tokyo, Graduate School of Medicine, Tokyo, Japan, [2]University of Massachusetts-Amherst, Department of Public Health, Massachusetts, United States, [3]King Faisal Hospital, Kigali, Rwanda, [4]Rwanda Biomedical Center, Kigali, Rwanda*
*Presenting author email: kimiyo@m.u-tokyo.ac.jp*

**Background:** Poor development is one of the most urgent and critical problems among HIV-positive children. Many studies have been conducted to identify barriers to healthy growth. Recently, the positive deviance approach has been advocated as a unique strategy in the field of child nutrition, which focuses on positive individual behaviors, rather than barriers. In this study, we analyzed HIV-positive children with healthy body mass index (BMI) status and identified the associated factors.

**Methods:** A cross-sectional study was conducted in Kigali, Rwanda. To obtain each HIV-positive child's BMI (< 5 years old), we measured their height and weight. We also carried out face-to-face interviews with their caregivers using a semi-structured questionnaire. BMI-for-age z-score in the normal range (+1>SD>-2) was considered as healthy BMI.

**Results:** In total, data from 596 pairs of HIV-positive children and their caregivers were included in the analysis. The mean BMI-for-age z-score was -0.62 (SD 1.30). In all, 79.9% of the children had a healthy BMI status. A multiple logistic regression analysis indicated that children whose caregivers took an initiative for their child's care arrangements were more likely to have healthy BMI status when compared to the child's initiative only (AOR 3.86, 95% CI: 1.16-12.85). However, the children whose caregivers took an initiative to ensure that the child's intake was adequate were less likely to have healthy BMI status than those who took part in maintaining their own calorie intake (AOR 0.04, 95% CI: 0.02-0.90).

**Conclusions:** Caregiver involvement was suggested as a positive element for the child's healthy BMI. Alternatively, both the child and the caregiver's participation would be necessary to ensure sufficient calorie intake for the child's BMI. To improve development among HIV-positive children, increased attention to role sharing of care and calorie intake among both caregivers and children is required.

## TUPED282

### ASSESSMENT OF THE UTILIZATION OF CULTURALLY-SENSITIVE DISCLOSURE COUNSELING TOOLS FOR HIV-INFECTED ADOLESCENTS AND CAREGIVERS IN WESTERN KENYA

C.I. McAteer[1,2], J. Aluoch[2], C. Mutiso[2], R. Ombitsa[2], W.M. Nyandiko[2,3], I. Marete[2,3], R.C. Vreeman[1,2,3]
*[1]Indiana University School of Medicine, Pediatrics, Indianapolis, United States, [2]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [3]Moi University, College of Health Sciences, School of Medicine, Department of Child Health and Paediatrics, Eldoret, Kenya*
*Presenting author email: carolemcateer@gmail.com*

**Background:** Disclosure of HIV status to children is a key aspect of their disease management; however, structured counseling resources to support disclosure are limited. Our objective was to evaluate the usage of culturally adapted tools for disclosure counseling with children and caregivers in Kenya and identify critical themes in disclosure counseling.

**Methods:** We evaluated disclosure counseling sessions offered as part of a 2-year, clinic-based intervention to support HIV disclosure for Kenyan children aged 10-15 years and their caregivers within the Academic Model Providing Access to Healthcare (AMPATH). Child, caregiver, and family counseling were offered at four HIV clinics. Disclosure counselors created individualized counseling plans for participants and documented disclosure status and psychosocial issues on a structured counseling encounter form. Counselors had access to culturally adapted resources (e.g. disclosure video narratives, HIV educational pamphlets) created from previous qualitative work with this cohort. To evaluate implementation of these resources and identify critical themes related to disclosure and child behavioral outcomes, we used thematic analysis of the counseling encounter notes, with progressive coding and constant comparison. Themes were coded and triangulated among multiple reviewers.

**Results:** Counselors documented 349 counseling encounters related to 122 children, using disclosure videos (127), HIV information books (128), and pamphlets (19). For caregivers of non-disclosed participants, common themes included disclosure preparedness and adherence management. Videos were most often used with caregivers to overcome disclosure barriers (e.g. child not ready, fear child's reaction) and initiate the disclosure process, particularly for children suspecting their status. Two themes arose related to post-disclosure in children: positive functioning (e.g. mild demeanor, accepting of HIV status) and poor functioning (e.g. worsened adherence, personalized HIV stigma). For "poor functioning" children, counselors used HIV information books and videos, encouraging children to understand and accept their HIV status. Counselors noted improved child adherence and psychosocial issues (e.g. stigma reduction, acceptance of status) after using the tools.

**Conclusions:** Culturally-adapted disclosure tools were used by disclosure counselors to mitigate disclosure barriers with non-disclosed caregivers and improve post-disclosure functioning. Understanding the content of typical disclosure counseling sessions provides input for the design of future disclosure counseling interventions and for counseling implementation.

## TUPED283

### PEDIATRIC HIV DISCLOSURE INTERVENTION IMPROVES KNOWLEDGE AND CLINICAL OUTCOMES IN HIV-INFECTED CHILDREN AND ADOLESCENTS IN NAMIBIA

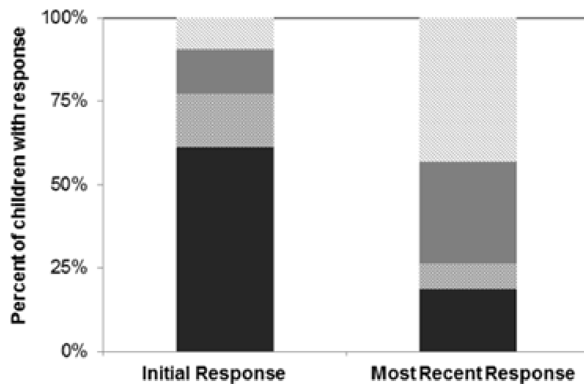
K. Beima-Sofie[1], N. Hamunime[2], L. Brandt[3], M. Shepherd[3], L. Feris[3], J. Uusiku[3], G. John-Stewart[1,4,5], G. O'Malley[1,6]
*[1]University of Washington, Department of Global Health, Seattle, United States, [2]Namibia Ministry of Health and Social Services, Windhoek, Namibia, [3]International Training and Education Center for Health - Namibia, Windhoek, Namibia, [4]University of Washington, Department of Epidemiology, Seattle, United States, [5]University of Washington, Department of Medicine, Seattle, United States, [6]International Training and Education Center for Health - University of Washington, Seattle, United States*
*Presenting author email: beimak@uw.edu*

**Background:** In 2010, Namibia's Ministry of Health and Social Services (MOHSS) developed and implemented a structured intervention to assist healthcare workers and parents/caregivers with HIV disclosure to children and adolescents.

We conducted an evaluation of HIV-infected children and adolescents enrolled in care to assess impact of the intervention on child health outcomes and knowledge.

**Methods:** Data was abstracted from electronic medical record databases and patient charts for HIV-infected children aged 7-15 years across 4 high-volume pediatric HIV clinics in Namibia. Disclosure rates, time to disclosure, and HIV knowledge in 314 children documented as participating in the disclosure intervention were described. Logistic regression was used to identify correlates of partial vs. complete disclosure. Paired t-tests were used to compare mean adherence percent and viral load before versus after enrollment among children who initiated the intervention in 2011.

**Results:** Among 314 children with documented participation in the disclosure intervention, 11% knew their HIV status at enrollment and 38% reached complete disclosure following enrollment. The average time to complete disclosure was 2.5 years (IQR: 1.2 - 2 years). Among children who reported no or incorrect knowledge of why they take their medicine, 83% showed improved understanding after the intervention, defined as knowledge of HIV status or adopting intervention-specific language to discuss their medication use.



| Category | Example Responses |
|---|---|
| Complete or accurate knowledge of HIV | "Because I am HIV positive" "For HIV and my body to be strong" |
| Adopts language from the intervention | "To keep the bad guys sleeping" "To make my soldiers strong" |
| Uses basic sickness or health descriptions | "To stay healthy and be strong" "To not be sick" |
| No or incorrect knowledge of HIV | "To cure pimples in my body" "I have a cough" |

*[Figure: Changes in HIV knowledge between enrollment and the time of data abstraction]*

Children who achieved complete disclosure were more likely to be older, have lower viral loads, and have been on ART longer. In comparisons before vs. 12-24 months after participating in the disclosure intervention, viral load decreased by 0.5 log copies/ml (N=53, p-value=0.006) while mean adherence scores increased by 7 percentage points (N=73, p-value=0.019) in children who had been on ART >18 months at enrollment and had pre and post enrollment measurements collected.

**Conclusions:** This HIV disclosure intervention was associated with improved disclosure rates, HIV knowledge, and clinical outcomes in HIV-infected children and adolescents.

## TUPED284

### TARGETING SERVICES ADOLESCENT GIRLS AND YOUNG WOMEN LIVING WITH HIV: SIMPLE MAY BE BETTER

M. Dunbar[1], D. Nhamo[2], G. Chapwanya[2], I. Mudkunye-Mahaka[1], A. Chingono[3], G. Kadzirange[3]

*[1]Pangaea Global AIDS, Harare, Zimbabwe, [2]Pangaea Zimbabwe AIDS, Harare, Zimbabwe, [3]University of Zimbabwe, Harare, Zimbabwe*

*Presenting author email: mdunbar@pangaeaglobal.org*

**Background:** The growing numbers of adolescent girls and young women (AGYW) living with HIV in sub-Saharan Africa face myriad challenges. SHAZ! (Shaping the Health of Adolescents in Zimbabwe) is a combination intervention designed to improve access and treatment adherence among AGYW living with HIV in Zimbabwe

**Methods:** 710 participants enrolled in an RCT of SHAZ! (life skills and livelihoods training, comprehensive SRH/HIV care and treatment) vs a control condition of clinical care and treatment support alone. Intent treat analysis assessed differences in outcomes across four domains: economic resources; treatment adherence and CD4; relationship power; and HIV risk behaviors.

**Results:** At enrolment, median age was 18, and CD4 count was 343 (200, 526). 30% had primary education or less; and 70% had not used a condom at last sex. At 18 months, study retention was 84%. Those reporting being in school or engaging in paid work increased from 34% to 61% in the intervention group compared to from 38% to 33% in the control group (p< 0.001). No changes were reported on measures of mental health or social support; however, high relationship power- as measured by the sexual relationship power scale -increased from 28% to 45% in the intervention group only. Overall, ART uptake increased from 48% to 74%, with an average 41 point increase in CD4 count and over 50% achieving CD4 counts of over 500. Reported adherence at 18 months was 98%. Experience of intimate partner violence decreased from 17% to 5%. While all of these improvements represented statistically significant changes from baseline to endline ( p< 0.01 or less), there were no statistically significant differences between study arms on these factors. No changes were observed from baseline to endline in condom use, or other risk behaviors such as transaction sex.

**Conclusions:** This analysis showed effects of SHAZ! on economic status and relationship power, but not on risk behaviour. The significant and meaningful shifts among ALL participants on treatment uptake and clinical outcomes suggest that targeted SRH/HIV services and treatment support - without necessarily overlaying additional complex interventions - has great potential to improve scale-up of treatment and adherence for this population.

## TUPED285

### IS DIFFERENTIATED CARE TRULY DIFFERENTIATED FOR ADOLESCENTS LIVING WITH HIV? QUALITATIVE FINDINGS FROM ZIMBABWE AND SOUTH AFRICA

L. Langhaug[1], M. Dunbar[2], G. Gumbo[2], N. Willis[3], P. Gomo[4], T. Crankshaw[4], A. Gibbs[4]

*[1]REPSSI, Harare, Zimbabwe, [2]Pangaea Global AIDS, Pangaea Zimbabwe AIDS, Harare, Zimbabwe, [3]AFRICAID, Harare, Zimbabwe, [4]Health Economics and HIV/AIDS Research Division, Durban, South Africa*

*Presenting author email: gwengumbo@gmail.com*

**Background:** To achieve the goal of '**Treat All',** the WHO has endorsed the **differentiated care model** - whereby service delivery models are targeted to specific requirements of each population. For adolescents, an emphasis of differentiated care is defined by the WHO as: equitable, acceptable, appropriate, accessible and effective. Employing differentiated care may be particularly important for adolescents living with HIV. Given that AIDS is the second leading cause of deaths for all adolescents, improving quality and effectiveness of HIV treatment is of paramount importance. This study reports on the differential SRH support needs between adolescents living with perinatally acquired HIV versus those with horizontally acquired HIV.

**Methods:** YPLWH (n=8) were trained as peer researchers to undertake qualitative interviews with their peers (aged 16-25) recruited from support groups in Zimbabwe (n=24) and from clinics in South Africa (n=24). There were equal numbers of young men and women. Discussions focused on disclosure, and access to SRH information and services. English language transcripts were thematically analysed.

**Results:** Key differences emerged between adolescents who acquired HIV-perinatally versus adolescents who acquired HIV horizontally. Adolescents living with HIV who acquired it horizontally displayed greater internalised stigma than those who had acquired HIV perinatally; this was reflected through more frequent use of words like "being diseased" and attributing acquisition to 'having behaved badly.' All participants faced HIV disclosure challenges; adolescents living with HIV acquired vertically highlighted frustrations in learning about their HIV-status long after their caregivers knew and being left out of treatment decisions. Lack of social support was more common in those who acquired HIV-horizontally. There were important similarities, in particular all young people's desire to receive appropriately-tailored services that respond to their specific needs and that enable them to take control of their health and wellbeing. Young people were also concerned with protecting others, through receiving timely ART care and support and comprehensive SRH services.

**Conclusions:** Adolescents living with vertically-acquired HIV have different SRH care and support needs to adolescents living with horizontally-acquired HIV. HIV and SRH services need to be tailored to support the differentiated YLHIV needs in order to promote optimal health outcomes.

## TUPED286

### FINDINGS FROM PROJECT KHULUMA: A MOBILE PHONE SUPPORT GROUP INTERVENTION FOR HIV-POSITIVE ADOLESCENTS IN SOUTH AFRICA TO ADDRESS THEIR MENTAL HEALTH AND WELLBEING NEEDS

A.S. Kydd[1], M. Biriotti[1], J. Koen[2], Z. Figerova[1], M. Ngobeni[3], T. Konkobe[3]

*[1]The SHM Foundation, London, United Kingdom, [2]The SHM Foundation, Johannesburg, South Africa, [3]The SHM Foundation, Pretoria, South Africa*

*Presenting author email: anna@shmfoundation.org*

**Background:** Owing to a conglomeration of psychosocial risk factors including the lack of social support, adolescents living with HIV/AIDS (ALWHA) are at increased risk of mental health problems leading to poor health outcomes. There is a need to develop models that provide regular psychosocial support to ALWHA that are immediate and accessible. With this challenge in mind the SHM Foundation designed and implemented the Khuluma model, providing support via mobile phone to groups of 10-15 ALWHA's from clinics in Pretoria and Cape Town. Khuluma is based on the

**Tuesday 19 July** Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

principle that support groups are an effective way of providing support, but there are barriers to attending them. Because it provides access to support whenever, wherever, and allows for anonymous communication, Khuluma breaks down some barriers (including worries about stigma and discrimination; lack of transport funds or time ) to adolescents' attendance. The model assists clinics as there no need for trained staff onsite or a designated space.. An evaluation of Khuluma was conducted based on pre-post data from 99 participants who participated between December 2013 and February 2015. The information-motivation-behavioural skills (IMB) model informed the assessment of changes to participants' perceptions of stigma, social support, knowledge of HIV and adherence to medication.
**Description:** Khuluma provides facilitated and interactive support to groups of 10-15 peers via text-message . Groups run for three months, participants can communicate amongst themselves and with a facilitator.. Guest speakers are invited to run discussions on topics such as nutrition or sexual health. Baseline and exit questionnaires are conducted. Text-messages are analysed for content.
**Lessons learned:** Participants clearly have a need/ desire to communicate openly with their peers, over 40,000 text-messages were sent between 99 participants - each participant sends 6 SMSs daily. Results from the evaluation show a significant increase in feelings of social support, a significant decrease in internalised stigma and some important insights into the complexities of medical adherence. Khuluma provides an effective way for making support accessible to ALWHA
**Conclusions/Next steps:** Khuluma has the potential to be expanded through clinics as a way of providing social support to ALWHAs using trained facilitators who do not have to be physically onsite.

## TUPED287

### *THIS IS ME*. A DOCUMENTARY HIGHLIGHTING EVERYDAY LIFE OF A HIV-POSITIVE ADOLESCENT IN SOUTH AFRICA GOING THROUGH THE JOYS AND CHALLENGES OF ADOLESCENCE

Z. Figerova[1], A. Kydd[1], J. Koen[2], M. Ngobeni[2], T. Konkobe[2]
*[1]The SHM Foundation, London, United Kingdom, [2]The SHM Foundation, Pretoria, South Africa*
*Presenting author email: zuzana@shmfoundation.org*

**Background:** Adolescence can be a beautiful time of life but at the same time this age brings a lot of challenges. These challenges are even more significant for adolescents living with HIV. In South Africa, over 15% of young women and 5% of young men aged 15-24 are infected with HIV (UNAIDS, 2010). Despite efforts to raise national awareness of HIV/AIDS and advance treatment options, there is still a lot of work to be done to address mental health challenges of these adolescents to make the general public aware of these challenges. There is a need to pay more attention to the mental health and psychological well being of young people living with HIV and create opportunities where young people can freely express how they feel. The SHM Foundation is creating a documentary *This is me* which takes an innovative and positive approach to highlighting the importance of addressing the mental health needs of HIV positive adolescents.
**Description:** *This is me* is a 15 minute documentary, the documentary will show the everyday life of a 16 year old boy who is HIV positive, who has a positive attitude to life and who, just like any other boy in his age, is going through the joys and challenges of adolescence. The film will follow him over two weeks, filming his every day life and the conflicts and challenges he faces at home, school and with friends due to being an adolescent living with HIV.
**Lessons learned:** Co-creation of the documentary with HIV positive adolescents is essential in order to get the messaging and tone right. It is critical that there are more opportunities to show what it is like for an HIV positive adolescent in South Africa to navigate through life with the condition and to become accepted and understood by our society, because only then they can live fulfilled and active lives.
**Conclusions/Next steps:** We plan that *This is me* will go on tour around South Africa, with showings taking place in schools as well as at international film festivals.

## TUPED288

### "WALKING TOGETHER": CULTURAL ADAPTATION OF AN EVIDENCE INFORMED PSYCHOSOCIAL INTERVENTION TO ADDRESS THE NEEDS OF PHIV+ YOUTH IN THAILAND

G. Pardo[1], C. Saisaengjan[2], S. Lakhonpon[2], J. Ananworanich[2,3], T. Bunupuradah[4], P. Goplan[1], D. Friedman Nestadt[5], C. Mellins[5], M. McKay[1]
*[1]New York University, McSilver Insititute/Social Work, New York, United States, [2]SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, [3]U.S. Military HIV Research Program, Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [4]The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [5]New York State Psychiatric Institute and Columbia University Medical Center, New York, United States*
*Presenting author email: gap2009@nyu.edu*

**Background:** Pediatric HIV has become an epidemic focused on adolescents, most of whom live in low resource countries with unmet psychosocial needs. Thailand has the highest HIV prevalence in Asia with more than 14,000 children with HIV. There is an acute need for evidence based interventions targeting mental health of perinatally infected HIV+ youth to improve adherence, reduce risky behaviors and decrease mortality rates.
**Description:** The Collaborative HIV Prevention and Adolescent Mental Health Program + (CHAMP+) is an evidence informed, family based HIV prevention and mental health promotion program developed specifically for pHIV+ early adolescents and their families, that has been pilot-tested in the U.S.A., Argentina and South Africa. Thai and US research teams used community-based participatory research (CBPR) methods to adapt CHAMP+ to the Thai cultural context. Formative research with pHIV+ youth, adult caregivers and health providers informed program changes to address language; cultural beliefs /concepts and Thai family life. "Walking Together" (Thai CHAMP+) consists of 11 sessions using a cartoon format and delivered via multiple family groups. Sessions focus on family communication, coping strategies, disclosure, stigma, social support, and HIV education. A small scale RCT pilot of the intervention is concluding this year with 88 pHIV+ youth participants.
**Lessons learned:** Culturally informed adaptations can be made while maintaining the core components responsible for program effect. The cartoon format (originally used in CHAMP+ South Africa) was selected by Thai stakeholders since it enabled reflective dialogue about key issues for HIV+ youth, made content available to those with limited literacy skills, and facilitated discussion of culturally "taboo' topics. Original cartoon story line was changed to reflect Thai culture and family life.
**Conclusions/Next steps:** Preliminary results of the current pilot indicate that the cultural adaption of CHAMP+ was critical to engagement and acceptability of the intervention within the Thai context. Feasibility and acceptability data plus feedback from participants will inform further adaptations to ensure intervention efficacy and effectiveness.

## TUPED289

### HIGH RISK FOR LOSS TO FOLLOW-UP AMONG ADOLESCENTS LIVING WITH HIV IN PUNE, INDIA

S. Nimkar[1], C. Valvi[1], S. Khadse[1], D. Kadam[1], A. Kinikar[1], I. Marbaniang[1], B. Rewari[2], A. Chandanwale[1], N. Suryavanshi[1], S. Patil[1], N. Nevrekar[1], P. Raichur[1], A. Gupta[3], V. Mave[1]
*[1]Byramjee-Jeejeebhoy Medical College Clinical Trials Unit, Pune, India, [2]National Professional Officer (ART), WHO, New Delhi, India, [3]Johns Hopkins University School of Medicine, Baltimore, United States*
*Presenting author email: nsmita13@gmail.com*

**Background:** Access to HIV care in paediatric population has increased substantially in developing countries through national programs. Existing data suggest that children are more likely associated to loss to follow-up due to vulnerability and multifaceted social challenges. We aimed to assess the rate of loss to follow up (LTFU) and risk factors associated among children visiting Sassoon General Hospital's ART centre in Pune, India.
**Methods:** We conducted a prospective cohort analysis of children (0-19 years) registered for care between 2000 and 2014. The cohort was divided into two age groups ≤12 years and >12 years. Multivariable Poisson regression was used to explore the association between age, gender, CD4 count, WHO staging and LTFU.
**Results:** 6156 children were registered for care during the study period. Of these, majority were male (60%), had a baseline CD4 count <350 cells/cu mm (67%) and were on ART (98%). 292 (4.7%) were lost to follow up. Total loss to follow up among children ≤12 years was 7/1000 person years (PY) as compared to 16/1000 PY in those >12 years (p<0.001). In multivariable analysis, children >12 years were at a higher risk of being lost to follow up [adjusted incident relative risk(aIRR) 1.95, 95% Confidence Interval (CI) 1.5 - 2.5] as compared to children ≤12 years. Lower CD4 counts (<200 cells/cu mm) was associated with higher risk of being lost to follow up (aIRR: 1.6, 95% CI: 1.1-2.1) as compared to those with CD4 counts >350 cells/cu mm.

Children who presented clinically in WHO stage IV disease were at higher risk (aIRR: 2.4, 95% CI: 1.7-3.2) of lost to follow up as compared to those in stage I disease.
**Conclusions:** Adolescents with HIV (>12years of age) have almost 2-fold higher risk for LTFU. Future studies should seek to understand barriers to retention in care among adolescents and consider interventions that include counselling, psychosocial support including peer support groups to reduce the risk of LTFU and improve the health, and quality of life.

## TUPED290

### PANGAEA GLOBAL AIDS & THE CLINTON HEALTH ACCESS INITIATIVE (CHAI) BEST PRACTICES CASE STUDY SERIES: ZVANDIRI CATS MODEL: SUPPORTING HIV+ ADOLESCENTS

I.C. Mahaka[1], K. Callahan[2], N. Willis[3], M. Rejbrand[4], K. Taylor[4], D. Chris[4]
*[1]Pangaea Global AIDS, Harare, Zimbabwe, [2]Clinton Health Access Initiative (CHAI), New York, United States, [3]AFRICAID Zvandiri, Harare, Zimbabwe, [4]Pangaea Global AIDS, Oakland, United States*
*Presenting author email: imahaka@pangaeaglobal.org*

**Background:** Pangaea Global AIDS, in partnership with the Clinton Health Access Initiative (CHAI), produced a series of case studies documenting and costing effective approaches to HIV service delivery in Sub-Saharan Africa. In Zimbabwe HIV-positive children and adolescents face challenges with adherence, retention and their overall psychosocial well-being. Africaid, an NGO based in Harare launched the Zvandiri program, which provides psychosocial and clinical support to HIV+ children and adolescents.
**Description:** Zvandiri interventions are led by Community Adolescent Treatment Supporters (CATS), HIV+ adolescents that play a central role in identifying and addressing barriers to adherence and retention through home visits, SMS messages and tablets to capture client data and adherence, and adolescent corners within clinics. Other CATS services include strengthening the capacity of health care providers to meet the needs of HIV-positive children and adolescents through trainings and mentorship.
**Lessons learned:** From August 2009 to December 2014, CATS conducted a total of 18,115 home visits in eight districts of Harare province; 12,248 were primarily for adherence support. In 2014, the CATS program in Harare province served more than 3,800 clients and registered over 1,100 clients in three additional provinces. By November 2014, a total of 1,476 health workers had been trained in providing adolescent friendly services for HIV-positive youth. In 2014, Zvandiri reported a 90 percent retention rate among clients served by CATS. Self-reported adherence by age was 90%, 72% and 81% for ages 5-9, 10-14 and 15-19 respectively. The cost of the CATS model in 2014 was $52.39 per client per year in Harare, however modeling suggests that with further roll-out through the government, the program could be maintained at a cost of $22.53 per client per year.
**Conclusions/Next steps:** The utilization of CATS at both facility and community levels strengthened the identification and support for individuals at risk for poor adherence and lost to follow up. Its approach includes facilitating an enabling social environment that has demonstrated improvements in the overall health and psychosocial well-being of their clients. This model - which is being scaled up nationally - can inform other countries that face similar challenges in reaching children and adolescents.

## TUPED291

### INSIGHTS ON THE COMPLEXITIES OF MEDICAL ADHERENCE AMONGST HIV-POSITIVE ADOLESCENTS IN SOUTH AFRICA

J.L. Koen[1], T. Konkobe[1], A. Kydd[2], Z. Figerova[2], M. Ngobeni[1]
*[1]SHM Foundation (South Africa), Project Khuluma, Sandton, South Africa, [2]The SHM Foundation (UK), London, United Kingdom*
*Presenting author email: tebogo@shmfoundation.org*

**Background:** Adherence to medication for any chronic illness is difficult, but HIV/AIDS-treatment can be particularly challenging, especially for adolescents living with HIV/AIDS (ALWHA). Adherence needs to be near perfect for ART to be effective. However, adherence is not just remembering to take medication as prescribed. There is strong evidence that various social, emotional and psychological factors can have a significant impact on adherence. Although there is increasing awareness of the factors that affect ART adherence, it remains difficult to accurately assess. Understanding and improving treatment adherence among adolescents requires attention.
**Methods:** The Khuluma Project provides psychosocial support to ALWHA in peer groups run via text-message. Participants complete a treatment adherence checklist at enrolment and after participation in Khuluma. Over three months, participants can communicate openly with one another along with a facilitator. With 99 participants having participated to date, there is rich conversation data that can be further analysed (over 40,000 text messages). To explore some of the complexities associated with adolescent ART adherence, the Khuluma team extracted text-message conversations related to the subject. These conversations were coded and thematically analysed using a flexible framework developed from relevant literature.
**Results:** At enrolment most participants reported, in the checklist questionnaire, that they had few problems with medical adherence. However, in Khuluma they began to talk openly about sometimes missing medication doses. In their own words participants were able to discuss the range of practical and emotional reasons that they might default on treatment, including disrupted routine, a lack of social support, feelings of anger, fear of stigma and trouble managing side-effects. There was no one reason why they missed their medication and their reasons in some cases varied over time. Participants encouraged one another to take their medication and discussed strategies for integrating treatment into their daily lives.
**Conclusions:** Understanding and improving medical adherence among ALWHA requires ongoing engagement and dialogue, and is better understood through conversation than check-list questions. The messages sent by the participants to each other about medication may be a valuable resource for designing health promotion campaigns or improving communication between health practitioners and patients.

## TUPED292

### DIAGNOSIS DISCLOSURE AMONG CHILDREN LIVING WITH HIV IN A RESOURCE LIMITED SETTING: AN OBSERVATIONAL STUDY FROM NORTH INDIA

R.C. Chauhan[1], S.K. Rai[2], S. Kant[2], R. Lodha[2], N. Kumar[2]
*[1]Pondicherry Institute of Medical Sciences, Puducherry, India, [2]All India Institute of Medical Sciences, New Delhi, India*

**Background:** With better understanding of HIV pathogenesis and availability of antiretroviral therapy, more children are growing and entering in teen age group, making informing children about their HIV status an important aspect of long-term disease management. There is little evidence on perception of caregivers on how and when this type of disclosure should take place in resource-limited setting.
**Methods:** A cross-sectional study was conducted during 2010-12 among a dyad of 156 children and their caregivers, attending pediatric clinic at a tertiary care hospital in Delhi, India. Study protocol was approved by the Institute Ethics Committee of AIIMS. After taking written informed consent; pretested structured questionnaire was administered to caregivers during routine clinic visits. Information regarding socio-demographic characteristics, awareness of their HIV status among children and caregiver's perception regarding disclosure was collected. Mean and proportions were calculated and chi-square and logistic regression test were applied.
**Results:** The mean age of children was 8.4 ±3.5 years. Among them, 73.7% were male and 39.1% were orphan. Among 156 enrolled children, 74.4% (n=116) were of ≥ 6 years and were assessed for disclosure. Only 18.1% (n=21) children had been informed of their HIV status. Of those under 9 years, 6.4% knew their status, whereas 18.4% of 9-11 years and 35.5% of 12-14 years children knew that they had HIV infection. Awareness among males (23.3%) was higher than females (3.3%). Both age and sex of child were significantly ($p < 0.01$) associated with disclosure status. Other factors favoring disclosure were orphan-hood, non-perinatal mode of transmission (OR = 4.32; 95% CI 1.01-7.12), ART initiation (OR = 4.21; 95% CI 1.03-6.98), and caregiver educated beyond primary level (OR = 1.89; 95% CI 1.03-3.26). Repeated enquiry regarding the visit to clinic was the most common reason (66.6%) for disclosure. In 52.4% children disclosure was done with the involvement of other family members. 82.5% caregivers felt the age of > 10 years is appropriate for disclosing the HIV infection status to the child.
**Conclusions:** Detailed guidelines on disclosure are required for children of school-going age with perinatal infection who are not on ART and with caregivers of low educational status.

### EXPLORING THE POTENTIAL OF A FAMILY-BASED PREVENTION INTERVENTION TO REDUCE ALCOHOL USE AND VIOLENCE AND PROMOTE CHILD MENTAL HEALTH WITHIN HIV-AFFECTED FAMILIES IN RWANDA

S. Chaudhury[1], F.L. Brown[2], C.M. Kirk[3], S. Mukunzi[4], B. Nyirandagijimana[5], J. Mukandanga[4], C. Ukundineza[4], K. Godfrey[4], L. Ng[6], R.T. Brennan[3], T.S. Betancourt[3]
*[1]Harvard University, Epidemiology/ Global Health and Population, Boston, United States, [2]Harvard University TH Chan School of Public Health, Global Health and Population, Boston, United States, [3]Harvard University TH Chan School of Public Health, Boston, United States, [4]FXB-Rwanda, Kigali, Rwanda, [5]Partners in Health, Inshuti Mu Buzima, Kigali, Rwanda, [6]Massachusetts General Hospital, Division of Global Psychiatry, Boston, United States*
*Presenting author email: sumona@mail.harvard.edu*

**Background:** Family-based interventions hold promise for promoting child mental-health and wellbeing for families affected by HIV in low- and middle-income countries (LMIC). HIV-affected families report higher rates of alcohol-use, intimate partner violence (IPV) and family conflict, which can have detrimental effects on children. Few evidence-based interventions exist to address these complex issues in Sub-Saharan Africa.
**Methods:** Quantitative and qualitative data from an 82-family pilot randomized controlled trial of a family-based intervention adapted and tested for use in HIV-affected Rwandan families, are explored here using a mixed methods approach to integrate findings. Family inclusion criteria were at least one adult HIV-positive caregiver with at least one school-aged child (7-17 years). Mean scores of self-reported caregiver alcohol, IPV and child mental health at baseline, post-intervention and after three months of follow-up among families assigned to the intervention, were examined and compared to those receiving treatment as usual. Individual semi-structured interviews were conducted with children and caregivers at baseline, post-intervention, and follow-up. Qualitative data from 35 intervention families' clinical notes and interview transcripts from 11 families identified as experiencing issues with conflict and alcohol-use were analyzed.
**Results:** Of the 61 caregivers in intervention families, most were female (n=42; 68.9%), HIV-positive (n=52; 85.3%), with a mean age of 41. Of 93 children in intervention families, most attended school (n=87, 96.7%). Alcohol was reported as a problem for many families in the intervention. Of participants reporting alcohol-use at baseline, those assigned to family-intervention reported less alcohol-use over time, compared to those receiving usual treatment. Nearly three-fourths (73%) of caregivers married or living with a partner reported an experience of IPV at baseline. Mean scores indicate reduced IPV among intervention participants over time compared to those receiving usual treatment. Reductions in alcohol use and IPV among caregivers are supported by qualitative reports of improved family functioning, lower levels of violence and problem drinking as well as improved child mental-health, among the intervention group.
**Conclusions:** Family home-visiting interventions merit exploration for their potential to reduce problematic caregiver behavior related to alcohol, IPV and family-conflict and promote child mental-health for families affected by caregiver HIV in Rwanda.

## TUPED294

### FAMILY-BASED PROMOTION OF MENTAL HEALTH IN CHILDREN AFFECTED BY HIV: A PILOT RANDOMIZED CONTROLLED TRIAL

T.S. Betancourt[1], L. Ng[2], C.M. Kirk[1], S. Chaudhury[3], R.T. Brennan[1], W.R. Beardslee[4], S. Stulac[5], S. Mukunzi[6], F.L. Brown[1], B. Nyirandagijimana[7], K. Godfrey[6], C. Mushashi[7], E. Nduwinmana[7], V. Sezibera[8]
*[1]Harvard University TH Chan School of Public Health, Department of Global Health and Population, Boston, United States, [2]Massachusetts General Hospital, Division of Global Psychiatry, Boston, United States, [3]Harvard University TH Chan School of Public Health, Departments of Epidemiology and Global Health and Population, Boston, United States, [4]Boston Children's Hospital, Department of Psychiatry, Boston, United States, [5]Partners in Health, Boston, United States, [6]FXB-Rwanda, Kigali, Rwanda, [7]Partners in Health, Inshuti Mu Buzima, Kigali, Rwanda, [8]University of Rwanda, Butare, Rwanda*
*Presenting author email: sumona@mail.harvard.edu*

**Background:** Children affected by HIV are at risk for poor mental health. We conducted a pilot randomized controlled trial (RCT) of the Family Strengthening Intervention (FSI), a family home-visiting intervention to promote mental health, improve parent-child relationships, provide HIV psychoeducation, and reduce conflict affecting children in families with caregivers living with HIV. We hypothesized that child and family outcomes would be superior to usual care social work services.
**Methods:** 82 families (N=170 children, 48.8% female; N=123 caregivers, 68.3% female) with at least one HIV-positive caregiver (n=103, 83.74%) and school-aged child (ages 7-17) (HIV+ n=21, 12.35%) were randomized to receive FSI or treatment-as-usual (TAU), stratified by single- or dual-caregiver families. Local research assistants blind to treatment conducted assessments of child mental health, parenting practices, and family functioning at baseline, post-intervention, and at 3- month follow-up. Multilevel modeling assessed effects of FSI on outcomes across three time points.
**Results:** At 3-month follow-up, children in FSI reported fewer symptoms of depression (β=-.221; p=.043) compared to TAU. FSI was differentially effective depending on family structure. Post-intervention, single caregivers in FSI reported more social support than those in TAU (β=.678; p=.005). Immediately post-intervention, children in FSI reported fewer indicators of good parenting compared to TAU (β=-.316, p=.048), but this difference was not maintained at 3-month follow-up (β=-.053, p=.749) likely reflecting the process of HIV disclosure in families. Qualitative findings support potential reductions in problematic alcohol-use and violence within FSI families.
**Conclusions:** Children and families affected by HIV merit special attention by policy-makers, health workers, and researchers. HIV-related stressors, family functioning, and child mental health are inextricably linked and can be addressed via family-based preventive interventions. Family-based prevention holds particular promise for reducing child mental health problems linked to caregiver HIV. Future research on FSI should further investigate the effects of family structure and potential for reductions in problematic alcohol-use and family violence. Future trials should examine the effects of FSI over time in trials powered to examine family configuration.

## TUPED295

### THE PASSAGES PROJECT: INITIAL OBSERVATIONS FROM A MULTI-COUNTRY INVESTIGATION INTO FACTORS THAT IMPACT TRANSITION FROM ADOLESCENT TO ADULT HIV CARE

C.R. Carty[1,2,3], J.S. Lambert[4,5], L. Sidloyi[3], C. Oprea[6], R. Pierre[7], C. Christie-Samuels[7], R. Hansudewechakul[8], S. Watanporn[8], M. Archary[9], E. Machado[10], M.D.F. Lago Garcia[10], G. Avramovic[4,5], M. Picone[3], M. D'Eredita[3]
*[1]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [2]University of Cape Town, AIDS and Society Research Unit, Cape Town, South Africa, [3]The Relevance Network, Johannesburg, South Africa, [4]University College Dublin, Dublin, Ireland, [5]Mater Misericordia University Hospital, Dublin, Ireland, [6]Victor Babes Clinical Hospital for Infectious and Tropical Diseases, Bucharest, Romania, [7]The University of the West Indies Mona, Mona, Jamaica, [8]Chiangrai Prachanukroh Hospital, Chiangrai, Thailand, [9]King Edward VIII Hospital, Durban, South Africa, [10]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil*
*Presenting author email: cracar@msn.com*

**Background:** Globally, the average age of perinatally HIV infected youth attending paediatric subspecialty programmes approaches the mid-teen years. With the concurrent swell of behaviourally infected adolescents, clinicians are faced with large populations of teenagers and young adults who require transition to adult settings. During this period of referral, many young patients become lost to care resulting in a population of drug experienced adolescents who are difficult to trace. To mitigate this, it becomes necessary to interrogate gaps in the existing frameworks designed to maintain youth populations in care, informed by adolescents themselves.
**Methods:** The Passages Project was conceived in response to empirical evidence across multiple sites that showed increases in non-compliance in the early-to-late teen years, which coincides with the age of transition to adult clinics. Geographically distant sites were selected based upon country profiles and HIV incidence/prevalence. Brazil, Ireland, Jamaica, Romania, South Africa, Thailand and the United Kingdom were selected to determine if challenges to successful transition were similar across sites. If so, an intervention that has far-reaching impacts could result from this investigation that involved in-depth interviews with adolescents, their caregivers and health care professionals (n=420). Topics included barriers to adherence, mental health, religiosity and social protection, to name a few. Data from the "complaint to care" cohort in the 5 low income countries (n=73, 46 male) were analysed using novel algorithms to create a concourse of themes.
**Results:** The analysis showed no significant difference between male and female respondents, and further suggested no significant differences across countries. The exceptions to this related to reasons for missed appointments and anxiety-related indicators. This, in conjunction with relatively low sample sizes, suggests that collapsing across additional locations could yield a more valid set of results.
**Conclusions:** The data suggest that
(1) a healthy sample was captured and analyzed and
(2) the analysis potentially produced the general findings needed to effectively inform a follow on study.
This, in combination with processing speeds of < 1 minute for the entire data set, suggests that further research into the viability of this approach is warranted.

# Ageing with HIV: evolving and additional needs and responses

## TUPED296

### How social work can support people living with HIV and changes in cognition: results of a mixed-methods, community-based research study

A.D. Eaton[1,2], J. Watchorn[1], S.L. Craig[2], J.W. McCullagh[1], C. Mukandoli[1], R. Wallace[1], D. McClure[1]
*[1]ACT - AIDS Committee of Toronto, Support Services, Toronto, Canada, [2]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada*
*Presenting author email: aeaton@actoronto.org*

**Background:** It is estimated that 50% of the 75,500 people living with HIV in Canada will be affected by at least an asymptomatic form of HIV-Associated Neurocognitive Disorder (HAND) (CATIE, 2015; St. Michael's Hospital, 2014). As the number of people living with HIV over the age of fifty increases, social workers and other helping professionals need to adapt to meet people's changing needs.
**Methods:** Using a Participatory Action Research (PAR) framework a research team comprised of social workers and people living with HIV developed an explanatory sequential mixed-methods study to understand the support service needs of people over the age of 50 who are living with HIV and concerned about HAND. Purposive and snowball sampling were combined to recruit research participants into a survey and interviews offered in English and French from April to November 2015 in Toronto, Canada. An iterative data analysis process was employed whereby three independent coders used NVivo to separately identify key themes. The peer researchers were presented with these analyses and the research team collaboratively determined the project's findings.
**Results:** 108 survey respondents identified:
a) their concerns about living with HIV and changes in cognition;
b) their knowledge and experience of social work; and
c) what gaps they identify in current HIV-related programs and services related to cognitive health.
66% of survey participants were aged 50-59 and 88% identified as male. 54% were diagnosed with HIV prior to the introduction of Highly Active Antiretroviral Therapy (HAART) in 1996. 20 survey participants, 25% of which identified as female, participated in interviews based on the survey responses. Interviewees detailed:
a) how the Social Determinants of Health have impacted their lives;
b) experiences with HAND screening/testing; and
c) how social workers and grassroots community-based HIV organizations can improve their work with older adults living with HIV.
**Conclusions:** Based on a sample of people living with HIV who are concerned about their cognitive health in an urban Canadian city, these findings have implications for the shape and content of programs and services for people aging with HIV as we work towards improved health outcomes for people living with and affected by HIV/AIDS.

## TUPED297

### Exploring experiences of older African-American males aging with HIV in the rural south-eastern United States

B. Blake[1], G. Taylor[2], R. Sowell[2]
*[1]Kennesaw State University, WellStar School of Nursing, Smyrna, GA, United States, [2]Kennesaw State University, Kennesaw, United States*
*Presenting author email: bblake@kennesaw.edu*

**Background:** It is estimated that 50% of adults living with HIV in the U.S. are 50 years of age and older. A disproportionate number of men who are HIV+ are African-American. With medications extending life expectancy for decades, HIV+ men are dealing with the disease in the context of other age-related illnesses. However, there is limited data regarding the experiences of older HIV+ African-American men. The purpose of this study was to explore the experiences of older African-American men living in rural areas in the southeastern U.S. who may be especially vulnerable due to limited resources.
**Methods:** In Spring 2015, data were collected through face-to-face interviews with 35 HIV+ African-American men living in 5 communities in the southern U.S. Inclusion criteria were: HIV+ for 5 years or greater, identifying as African-American, 50 years of age or older, and providing informed consent. The guiding interview question was "Can you tell me what it is like aging with HIV in a rural community?" Demographic data were also collected. Verbatim transcripts of the audio-recorded interviews were analyzed using content analysis.
**Results:** The men in the study ranged from 49 to 66 years of age ($x$ = 55.6), and had lived with HIV for a mean of 20.9 years. Nine men had less than a high school education with 16 having completed technical school or at least some college. Nineteen men reported an income of less than $10,000/year. Twenty-seven men currently live alone. Five men had been diagnosed with AIDS. The qualitative analysis of study transcripts revealed 6 overlapping themes and 21 sub-themes. Primary themes included: *Stigma, Doing Fine, Family Support, Self Care Behaviors, Access to Resources, and Dealing with Age Related Diseases and HIV.*
**Conclusions:** The majority of men reported they have what they needed and remained positive. Men acknowledged facing stigma, but their family support is strong. Some men reported their belief that HIV has changed their lives for the better. This study provides new insight into the lives of rural African-American men, and expands our understanding of how these men are dealing with HIV and why many return or remain in rural communities.

## TUPED298

### Positive aging: Indigenous peoples aging with HIV/AIDS

C. Ryan[1], R. Jackson[2], A. King[3], R. Masching[4], C. Gabel[5]
*[1]McMaster University, Health, Aging & Society, Hamilton, Canada, [2]McMaster University, Health, Aging & Society & Social Work, Hamilton, Canada, [3]Simon Fraser University, Health Sciences, Vancouver, Canada, [4]Canadian Aboriginal AIDS Network, Halifax, Canada, [5]McMaster University, Health, Aging & Society & Indigenous Studies, Hamilton, Canada*
*Presenting author email: ryancr@mcmaster.ca*

**Background:** Largely due to treatment advances, the number of older people living with HIV is growing. For Indigenous peoples in Canada this is an important area of concern given over-representation in the HIV epidemic. This research contributes a novel focus on positive aging experiences of older HIV-positive Indigenous peoples within Indigenous contexts.
**Methods:** Using community-based research informed by Indigenous methodologies, we conducted four sharing circle sessions and four in-depth interviews (n=34) with participants attending the Canadian Aboriginal AIDS Network's Wise Practices Conference. Separate sessions were held for HIV-positive men and women. One session explored the perspectives of community/health service providers. All participants self-identified as First Nations, Inuit or Métis with participants ranging in age from 32 to 63 and HIV-positive for 5 to 29 years. Thematic analysis was used to extrapolate themes.
**Results:** Several interconnected themes (dimensions of health) emerged in our analysis as important in the context of successful aging (SA) for Indigenous people living with HIV and facilitating holistic health: spiritual (connection to land, ceremonies); social engagement (connections with families, community, tribal nation); physical (e.g., diet, exercise, managing co-morbidities, adherence and abstinence from substance use); emotional (e.g., cultivating self-love and acceptance); and mental (confronting stigma, cultivating self-esteem, achieving self-acceptance). The way in which individuals find their own balance between the five dimensions manifests in a nonlinear way. Recognition of the interconnectedness of the five dimensions means that individuals can move freely from one dimension to the next, and back again, until the individual finds the right balance necessary to actualize SA.
**Conclusions:** Based on the need for research identified in this project we are working towards building a larger exploratory study to examine ways in which Indigenous peoples experience growing older living with HIV. Our goal is to identify culturally resonate approaches to care for this population to support emerging practice implications that suggest the need for community and health services to conceptualize and deliver social/health care from within an Indigenous holistic worldview. It is essential that such research be developed in ways which are congruent with Indigenous culturally-defined notions of health.

## TUPED299

### "You're suffering all these things and you keep going backwards and forwards": experiences of the menopause among women living with HIV in the United Kingdom

J. McGregor-Read[1,2], F. Pettitt[1,2], S. Petretti[2], F. Burns[3], R. Gilson[3], C. Sabin[3], S. Tariq[3]
*[1]UK-CAB, London, United Kingdom, [2]Positively UK, London, United Kingdom, [3]UCL, Research Department of Infection & Population Health, London, United Kingdom*
*Presenting author email: spetretti@positivelyuk.org*

**Background:** Improvements in survival due to antiretroviral therapy (ART) have led to a shift in the age distribution of people living with HIV, with increasing numbers of women living with HIV (WLWH) reaching menopausal age. We present results from a qualitative study exploring experiences of the menopause among WLWH in the UK.
**Methods:** In collaboration with an HIV charity and two peer researchers, we conducted three focus group discussions (FGDs) in 2015 with 24 WLWH aged 43-62. All FGDs were transcribed verbatim and analysed thematically in NVivo 10.0. This work is part of the PRIME study, a mixed-methods observational study exploring the impact of the menopause on WLWH's health and wellbeing.

**Tuesday 19 July** Poster Exhibition

Wednesday 20 July

Thursday 21 July

Friday 22 July

Late Breaker Posters

Author Index

**Results:** Women described a lack of prior knowledge, leaving them under-prepared for menopausal symptoms. For women born in Sub-Saharan Africa (n=16), this was exacerbated by cultural taboos around discussing menopause, and loss of kinship networks during migration.
Menopause in the context of HIV brought particular challenges. Participants were concerned that menopause could be precipitated by HIV-infection or ART, whilst some were reluctant to take further medication such as hormone replacement therapy when already on ART. Common symptoms such as hot flushes, mood changes and poor sleep, sometimes impacted on ability to adhere to ART. Many participants did not recognise their menopausal symptoms, instead attributing them to ART side-effects or HIV. Furthermore, they found themselves "going backwards and forwards" between primary healthcare providers (HCPs) and HIV-physicians when seeking advice and clinical care, often leading to frustrating delays.
Participants highlighted the importance of supportive HCPs and accessible information on HIV and the menopause, and the need for ongoing peer-support, many describing their participation in the FGDs, often their first opportunity to discuss menopause with other WLWH, as "empowering".
**Conclusions:** This is one of the first qualitative studies to explore experiences of the menopause in WLWH. Participants encountered particular challenges in the recognition and management of the menopause as a result of also being HIV-positive. Increasing awareness among patients and HCPs, developing HIV-specific patient resources, and peer-support networks may help support WLWH at this stage in their lives and limit negative impacts on their HIV care.

## TUPED300

### SOCIAL NETWORK AND SUPPORTS AMONG OLDER GAY AND BISEXUAL MEN: THE IMPACT OF HIV

E. Seidel[1,2], M. Brennan-Ing[1,3], B. Larson[4], S. Karpiak[1,3]
*[1]ACRIA, Applied and Translational Research, New York, United States, [2]Fordham University, New York, United States, [3]New York University College of Nursing, New York, United States, [4]Center on Halsted, Chicago, United States*
*Presenting author email: lseidel@acria.org*

**Background:** As of 2015, half of those with HIV in the U.S. are age 50 and older, and 60% are gay/bisexual men (CDC, 2013). Older gay/bisexual men tend to have friend-centered social networks, regardless of HIV status. HIV-positive older adults are at high risk for multimorbidity, leading to increased needs for caregiving and support. Perceptions of social support sufficiency have been identified as critical resources in coping with illness. We examined the impact of HIV-infection on the social network configuration, dynamics and support needs of gay/bisexual men 50 and older.
**Methods:** Data was derived from a convenience sample of 146 men age 50 and older who self-identified as gay/bisexual at an LGBT community center; 46% reported being HIV-positive. The HIV-positive group were younger than the HIV-negative group (55.4 vs. 63.4 years). Two-thirds of HIV-positive group identified as Black or Hispanic, while in the HIV-negative group 16% were racial/ethnic minorities. Bivariate analysis of group differences on social support resources employed chi-square tests and one-way ANOVAS. Perceptions of instrumental and emotional support sufficiency indices were regressed on HIV status and demographic, health, and social support variables to examine the impact of HIV on perceived social support.
**Results:** Older gay/bisexual men with HIV reported lower income adequacy, and greater multimorbidity compared with their peers. HIV-positive men received more assistance from family, but were also more likely to perceive instrumental and emotional support as insufficient. Regression models on instrumental and emotional support sufficiency indices found demographic, health, and social support factors as significant covariates ($R^2$ = .35 and .37, respectively), but HIV status was not significant when controlling for other factors.
**Conclusions:** HIV-positive older gay/bisexual men have greater needs compared with their non-infected counterparts, as evidenced by inadequate incomes and greater multimorbidity. The high levels of unmet need for informal social support leads to the conclusion that HIV-positive sexual minority men will increasingly turn to community-based sources for needed support. It is vital that policies are in place to strengthen the social resources of older gay/bisexual men with HIV, and assuring that community-based providers have the competency and resources necessary to serve this population.

## TUPED301

### DIFFERENCES IN SOCIAL SUPPORT RESOURCES AMONG OLDER ADULTS WITH HIV IN SOUTH AFRICA AND UGANDA: FINDINGS FROM THE RESEARCH ON OLDER ADULTS WITH HIV (ROAH) AFRICA PROJECT

M. Brennan-Ing[1,2], K. Porter[1], J. Seeley[3], C. MacPhail[4], M. Kuteesa[3], L. Geddes[5], V. Minichiello[6], S. Karpiak[1,2], F. Venter[7], J. Negin[8]
*[1]ACRIA, Center on HIV and Aging, New York, United States, [2]New York University, College of Nursing, New York, United States, [3]MRC Uganda Viral Research Institute, Uganda Research Unit on AIDS, Entebbe, Uganda, [4]University of New England, Armidale, Australia, [5]University of New South Wales, The Kirby Institute, Sydney, Australia, [6]University of Newcastle, School of Medicine and Public Health, Callaghan, Australia, [7]University of Witwatersrand, Johannesburg, South Africa, [8]University of Sydney, Sydney, Australia*
*Presenting author email: mbrennan@acria.org*

**Background:** The population of adults 50 and older with HIV is growing in sub-Saharan Africa as antiretrovirals become more widely available, and is currently estimated at over 3,000,000. Research finds this group suffer high rates of comorbid diseases in addition to HIV, suggesting they will require increasing assistance from their informal social networks. But there is little data on the social network dynamics of these HIV-positive older adults.
**Methods:** Data were obtained from ROAH Africa sites in Uganda (UG) and South Africa (SA) on adults 50 and older with HIV from 2013 to 2015. In UG (N = 101), 58% were women and the average age was 61 years. In SA (N = 108), 72% were women and the average age was 58 years. Questions on social support resources were adapted from the ROAH U.S. study (Brennan, Karpiak et al., 2009), and significant differences were examined using Fisher's Exact Tests.
**Results:** SA adults were more likely to report that they lived alone (22%) compared to their UG counterparts (9%). UG adults were more likely to report having children and great-grandchildren in their households (64% and 65%, respectively), compared to SA (32% and 31%, respectively). Except for keeping house/preparing meals, SA adults were significantly more likely to report instrumental help and emotional support from family members, and were significantly more likely to report all types of assistance/support from friends, compared to older adults with HIV in UG. SA adults were more likely to perceive that they had received all the instrumental help needed compared with UG (67% and 32%, respectively). Although UG older adult were more likely to report that emotional support was always available compared to SA (64% and 9%, respectively), they were significantly less likely to indicate the emotional support they received was adequate (45% and 67%, respectively).
**Conclusions:** Despite high levels of informal support in both countries, sizeable proportions felt that support from family and friends was insufficient to meet their needs. Given the significant differences between samples, research is needed to better understand the cultural/societal factors affecting social care among older adults with HIV in sub-Saharan Africa.

## TUPED302

### LONG-TERM SURVIVORS: KICKING AIDS SURVIVOR SYNDROME

H. Tessema[1], T. Anderson[2]
*[1]ACRIA, Training Center, New York, United States, [2]Let's Kick A.S.S, San Francisco, United States*
*Presenting author email: ht519@nyu.edu*

**Background:** There are 1.2 million persons with HIV (PWH) in the U.S., and 50% are over age 50; a proportion that will rise to 70% by 2020. Older PWH are living longer due to effective antiretroviral therapy. There is a unique distinction to be made between HIV/AIDS Longterm survivors and those who have been recently infected and diagnosed with HIV. The two groups have distinctly different psychosocial and clinical needs. Longterm survivors are defined as those who were infected with HIV prior to the development of Protease Inhibitor drugs in the mid1990s. Longterm survivors experience multimorbidity as well as AIDS Survivor Syndrome.
**Methods:** In San Francisco, ACRIA and Lets Kick ASS have worked together to train HIV and Aging providers to create appropriate community based responses for Longterm survivors dealing with AIDS Survivor Syndrome, defined as the collection of signs & symptoms affecting longterm survivors, including: depression, survivors guilt, lack of future orientation, personality changes, anger, anxiety, low self-esteem, insomnia, social withdrawal & isolation, hopelessness, substance abuse, sexual risk-taking; and/or emotional numbness stemming from post-traumatic stress. Let's Kick ASS has disseminated the "Longterm Survivors Declaration" to build awareness about AIDS Survivor Syndrome and also to focus on survivors' resiliencies from decades of living with HIV. The provider trainings were based on the NOAH model, including community assessment, comprehensive training, follow-up, and NYC based mentorship for select training participants.
**Results:** There were many lessons learned, including the need for HIV providers to be trained on specific clinical and psychosocial needs associated with Longterm sur-

vivors. There is also low knowledge and preparedness among aging providers (i.e. senior center staff, and Gerontology) to assess and adequately respond to Longterm survivors within their caseload who disclose their HIV status.
**Conclusions:** Ongoing training for both HIV and Aging providers in San Francisco in order to equip them with information needed to adequately respond to the needs of Longterm survivors with AIDS Survivor Syndrome. Also, mobilization of local key stakeholders to advocate for continued provider education with a focus on resiliency and coping for Longterm survivors with AIDS Survivor Syndrome.

## TUPED303

### INTIMATE PARTNER VIOLENCE AMONG OLDER WOMEN WITH HIV

C. MacPhail[1,2], M. Brennan-Ing[3], K. Porter[3], V. Minichiello[4], S. Karpiak[3], J. Negin[5], F. Venter[2]
*[1]University of New England, School of Health, Armidale, Australia, [2]Wits Reproductive Health and HIV Institute, University of the Witwaterstrand, Johannesburg, South Africa, [3]ACRIA, New York, United States, [4]LaTrobe University, ARCSHS, Melbourne, Australia, [5]University of Sydney, School of Public Health, Sydney, Australia*
*Presenting author email: cmacphai@une.edu.au*

**Background:** There is increasing evidence of bidirectional links between HIV and intimate partner violence (IPV), particularly for women in sub-Saharan Africa. Much of the literature is focused on adolescent women; however the growing ageing HIV-infected population requires an assessment of IPV among older women.
**Methods:** We conducted interviews between late 2014 and early 2015 with patients aged 50 years and older attending a HIV treatment facility for routine monitoring visits in Johannesburg. Patients were approached in the waiting room, consented and interviewed in a private consulting room. Data were entered into Stata SE 13 and analyzed descriptively. We report on data from female participants and their IPV experience documented by the WHO intimate partner violence scale.
**Results:** 108 people participated in the survey, of which two-thirds were female (n=78). Mean age of female participants was 57.9 years with over 70% being single (either widowed, divorced/separated or never married). At the time of the interview two-thirds reported not having a partner and not being sexually active in the past 12 months. Approximately one-quarter of women reported ever experiencing partner violence more than 6 months ago. Almost 20% reported having been threatened into coercive sex. 20% also reported a partner using physical force (hit, held down or threatened with a weapon) to coerce sex. Other reports of violence included being choked, threatened with a knife or gun (21%); beaten up, burned or scalded 26%; pushed, grabbed or slapped (30%) or; had their hair or arm twisted or an object thrown at them (31%). Given that women were overwhelmingly single, reports of partner violence in the past 6 months were low (under 2%).
**Conclusions:** This cohort of older women with HIV report more lifetime IPV than has previously been documented in partnered South African women aged 15-49 years. These findings suggest that HIV seropositive older women's experience of violence might have directly or indirectly contributed to their HIV transmission and could impact on their autonomy in accessing and remaining in care. Routine IPV screening of these older women is warranted.

## TUPED304

### THE HEALTH CARE EXPERIENCES OF ADULTS AGED 50 YEARS AND OLDER LIVING WITH HIV IN BOTSWANA

K. Matlho[1], R. Lebelonyane[2], T. Driscoll[1], J. Negin[1]
*[1]University of Sydney, Public Health, Sydney, Australia, [2]Ministry of Health Botswana, HIV Prevention and Care, Gaborone, Botswana*
*Presenting author email: kabo.matlho@sydney.edu.au*

**Background:** HIV has been transformed from a death sentence to a chronic illness due to the advancement of antiretroviral treatment. Nevertheless, in Botswana, older adults living with HIV remain profoundly marginalised. According to the Botswana AIDS Impact Survey, the percentage of older people living with HIV has risen over time. This study aimed to examine how older people cope with living with HIV in Botswana.
**Methods:** This was a qualitative study in which 50 in-depth semi-structured face-to-face interviews were conducted with adults aged 50 years and above living with HIV. Recruitment was through healthcare facilities. Questions focused on socio-demographic characteristics as well as information on HIV diagnosis and probable acquisition, transmission, relationships, aging and co-morbidities. Thematic content analysis was used in the analysis, interpretation, and validation of the qualitative data.
**Results:** Most interviewees regarded themselves as long-time survivors who now struggle with both the challenges of aging with HIV as well as institutionalized ageism, stigma and social isolation. Other interviewees stated that they were newly infected and bemoaned the lack of prevention campaigns aimed at older people. Stigma and discrimination related to HIV and aging, the challenge of co-morbidities, and a general lack of age-appropriate service provision and support from practitioners across various fields hinders access to care. Interviewees stated that most health providers mistakenly assume that older people are not sexually active.
**Conclusions:** HIV presents a formidable challenge in Botswana, as older people living with HIV must confront issues relating to not only their health but also issues of morality and sexual expression. Even though Botswana's management seem to recognize HIV as a public health challenge, it's focused intervention seem to put greater emphasis on HIV in the context of a sexual transmitted infection rather than a chronic lifelong infection hence the need to increase the visibility and policy priority of aging and HIV in Botswana to unravel the complexity of managing HIV versus treatment effects versus aging versus concurrent disease.

## TUPED305

### ACCESSIBILITY OF ELDERLY ADULTS TO HIV SCREENING SERVICES IN CAMEROON

A. Rogers Awoh[1], A. Adedimeji[2]
*[1]Research for Development International, Health Programs, Yaounde, Cameroon, [2]Albert Einstein College of Medicine, New York, United States*
*Presenting author email: rogers.ajeh@r4dinternational.org*

**Background:** Older persons are believed to lack access to even basic healthcare and, crucially, to have less access to services than do younger age-groups, suggesting an element of age-related exclusion (UN, 2002;African Union, 2003; Lloyd-Sherlock P et al, 2010) . The UNAIDS update for 2009 stated that "even though the largest share of new infections in many African countries occurs among older heterosexual couples, relatively few prevention programmes have specifically focused on older adults" (UN, 2009).
**Methods:** We administered structured questionnaires on 321 elderly adults aged ≥55 years, selected through an incidental sampling techniques in two Cameroon communities. Data were analysed using Epi-Info 7. Descriptive and analytic statistics was used to measure access. Chi-Squared test was used to test for association between socio-demographic characteristics and access to HIV screening. Accessibility to HIV screening was defined as having done at least an HIV screening test at least once over a lifetime.
**Results:** The median age of the participants was 59years. The sex distribution for males and females was 54.5% and 45.5% respectively. 99/321(30.1%) had never done an HIV test in their entire life. Amongst those who had done an HIV test, only 136/233(58.4%) had done it within the past one year. Just 132/321(41.1%) reported that a doctor or nurse ever requested an HIV test for them in their entire life. Factors associated with access ($P < 0.05$) included; occupation, average monthly income, level of education and living with a chronic disease.
**Conclusions:** These results suggest that elderly people have limited access to HIV/AIDS services. There is need for appropriate measures especially from the dimension of health care providers to improve access to health care services amongst these elderly adults.

## TUPED306

### RESEARCH ON OLDER ADULTS WITH HIV IN UGANDA RESEARCH ON OLDER ADULTS WITH HIV IN UGANDA: A FEASIBILITY STUDY OF A SURVEY TOOL

W. Manyara, ROAH Uganda, University of Sydney
*HelpAge International, Programmes, Nairobi, Kenya*
*Presenting author email: wamuyu.manyara@helpage.org*

**Background:** HIV is having an impact on those aged 50 years and older. In sub-Saharan Africa, there are over 3 million older PLHIV representing more than 13% of the region's PLHIV. Emerging evidence has suggested that even in resource-limited settings, almost normal life expectancy, including that of older people can be expected once on ART.
The study sought to examine social support, sexual behaviour and overall health status among older PLHIV in Uganda and determine their unmet social and service needs in order to improve their quality of life and access to healthcare.
**Methods:** Both quantitative and qualitative data collection methods were used with 101 older PLHIV being interviewed on issues around their health, social behavior and well-being. The quantitative component was conducted through face-to-face one-on-one interviews. The survey included selected items from standardised and validated measures to allow for comparison to other extant research. Eleven in-depth interviews were conducted at the rural site and four at the peri-urban site. A framework involving developing a thematic structure for interpretation was used for the qualitative analysis.
**Results:** Levels of emotional support were seen as adequate by the majority of respondents but instrumental support, including financial support, help around the

house, assistance with daily living, was needed by most. Transport to health facilities was challenging for many and had the potential to hamper adherence to treatment and maintenance of health status. There were significant differences between men and women in sexual behavior. About half of older men were sexually active compared to only 14% of older women. Over half of respondents reported not using a condom with their spouse and the vast majority had disclosed to their partner.
**Conclusions:** The study serves as a basis for future work that could highlight challenges and opportunities to respond to HIV among older adults. It provides a clear pathway to strengthening the evidence based on older PLHIV in Uganda and subsequently in other parts of Africa, clearly demonstrates the feasibility and acceptability of the research and serves as a springboard for future work that could highlight challenges and opportunities to respond to HIV among older adults.

## TUPED307

### "WELL, THEY JUST GAVE UP": OTHERING AS PART OF THE SURVIVAL EXPERIENCE OF OLDER MEN WITH HIV IN NEW YORK CITY

C. McCullagh
*Columbia University, Social Work, New York, United States*
*Presenting author email: cam2316@columbia.edu*

**Background:** At present, half of those living with HIV in New York City are over 50 and many of these individuals are long-term survivors, reflecting the transformation of HIV from a life-threatening illness to a chronic disease. However, the distinctive lived experiences of older long-term survivors with HIV/AIDS have gone relatively understudied. While the use of moral narratives as a form of differentiation and internalized stigma have just began to be explored among this population, one aspect that has yet to be studied is the use of othering. This paper fills this gap.
**Methods:** Twenty in-depth open-ended interviews were conducted with older (ages 50 to 76) men who were long-term survivors of HIV/AIDS (time since diagnosis, years 15 to 30). The sample is predominantly Black/African American (70% Black/African American, 15% Hispanic Latino, 10% Bi-racial/Other, 5% White), gay (65% gay, 20% bisexual, 15% heterosexual), unemployed (80% unemployed) and educated (40% completed some or all college and 50% completed high school or GED program). Participants were recruited via posted fliers at a food and nutritional program for people living with HIV/AIDS in New York City. Interviews elicited participants lived and survival experience. Interviews were transcribed verbatim, and coded using ATLAS.ti, guided by the principles of Colaizzi's (1978) descriptive phenomenological method.
**Results:** All participants described how HIV/AIDS had led to multiple losses in their lives, this was particularly pronounced in those who identified as gay. Participants described losses through stigma, for example abandonment by friends and families as well as through death, for example death of a friend or partner from HIV. They described viewing these deaths, first through with fear and subsequently from an exclusionary othering lens. Whereby, participants reported feeling dominance over those who had died, ascribing those who had died with characteristics relating to weakness and defeatism. Moreover, the participants reported that othering those who had died imbued them a sense of personal empowerment.
**Conclusions:** Findings highlight the importance of othering as part of the survival process among long-term male survivors with HIV/AIDS.

## TUPED308

### TELLING IT LIKE IT IS: THE MULTIPLE LOSS JOURNEY WITH A SPANISH SOUL

S.E. Lopez Lopez[1,2], Y. Perrault[3]
[1]*AIDS Bereavement and Resiliency Project of Ontario, Peer Support, Toronto, Canada,* [2]*Toronto People with AIDS Foundation, Peer Engagement Volunteer, Toronto, Canada,* [3]*ABRPO, Executive Director, Toronto, Canada*
*Presenting author email: samuelernestolopez@gmail.com*

**Background:** There are an increasing number of PHAs who have immigrated to Toronto from Latin-American countries. In addition to the stigma of being associated with marginalized communities and living with HIV, these individuals often come with stories of war-related violence. Latinos PositivosToronto (LPT) requested support for creating a culturally-relevant dialogue tool to assist members of this community in openly talking about their complex multiple loss histories. Spanish Interpreters from LPT reached out to the AIDS Bereavement and Resiliency Project of Ontario (ABRPO) who had developed a program on Multiple Loss and Community Devastation: *Survive to Thrive*.
**Methods:** As part of *Survive to Thrive*, ABRPO created a "Multiple Loss Journey" (MLJ)- a large visual tool that supported community awareness and dialogue related to the issues and task associated with accommodating the challenges of ongoing loss. Through a community needs assessment, the members of LPT decided that the direct translation of this MLJ was insufficient. As a result, ABRPO sat for 3 days with 15 members of LPT from 5 Latin American countries, to adapt it to a Spanish version of the MLJ. Each concept on the map was carefully deconstructed and elaborated upon to identify Spanish concepts and words appropriate to this ethno-racial community.
ABRPO supported LPT by producing a colourful 6 foot wall map of this Spanish "Sendero de Pérdidas Múltiples".
**Results:** Direct translations of AIDS-related materials and tools are not culturally appropriate for non -English speaking PHAs. By developing a partnership between experts and community, a stronger tool was developed that will not only be highly relevant for Spanish-speaking multiple loss survivors, but will be a significant resource for ABRPO.
**Conclusions:** With this dialogue tool in place, Latinos Positivos Toronto is better able to partner with ABRPO to train a core-group of PHAs to deliver a Spanish version of the "Survive to Thrive "program that accompanies this Multiple Loss Journey.

# PREVENTION INTERVENTIONS AND THEIR EFFECTS ON THE LIVES AND RELATIONSHIPS OF PEOPLE LIVING WITH HIV

## TUPED309

### GENDER INEQUALITIES INFLUENCE HIV-SEROSTATUS DISCLOSURE: QUALITATIVE STUDY AMONG HIV-POSITIVE WOMEN AND MEN REPORTING SERO-DISCORDANT PARTNERSHIPS IN DURBAN, SOUTH AFRICA

D. Bhatia[1], A. Harrison[1], L. Matthews[2,3,4], M. Kubeka[5], C. Milford[5], I. Wilson[6], C. Psaros[2,7], S. Safren[8], D. Bangsberg[2,3,4], J. Smit[5]
[1]*Brown University School of Public Health, Department of Behavioral and Social Sciences, Providence, United States,* [2]*Harvard Medical School, Boston, United States,* [3]*Massachusetts General Hospital, Global Health, Boston, United States,* [4]*Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States,* [5]*Maternal Adolescent and Child Health Research (MatCH Research), University of the Witwatersrand, Department of Obstetrics and Gynaecology, Durban, South Africa,* [6]*Brown University School of Public Health, Department of Health Services, Policy & Practice, Providence, United States,* [7]*Massachusetts General Hospital, Behavioral Medicine Program, Department of Psychiatry, Boston, United States,* [8]*University of Miami, Department of Psychology, Miami, United States*
*Presenting author email: abigail_harrison@brown.edu*

**Background:** This qualitative study investigated the dynamics of HIV-serostatus disclosure with a focus on gender inequities among HIV-positive men and women reporting sero-discordant partnerships in Durban, South Africa. HIV-serodiscordance contributes to high HIV incidence in southern Africa, yet disclosure rates remain low among men and women in sero-discordant partnerships. Gender power inequality within relationships can increase HIV infection risks for women, requiring greater attention towards addressing gender relations and HIV disclosure.
**Methods:** Thirty-five in-depth interviews were conducted with 15 HIV-infected men and 20 HIV-infected women (not couples) reporting uninfected or unknown-serostatus partners and enrolled in HIV care, from four public sector clinics near Durban, as part of a study exploring participant experiences with safer conception counseling. Themes were identified using a structured coding scheme, permitting investigation of men's and women's attitudes and behaviors toward HIV-serostatus disclosure, and the process and experience of sharing (or not sharing) HIV-serostatus with a partner. Promoters and barriers of HIV-serostatus disclosure emerged as important themes affecting periconception HIV-risk behavior. Data analysis explored narratives of HIV-serostatus disclosure through the lens of gender inequality, focusing on reasons for non-disclosure and links to sociocultural gender dynamics.
**Results:** Socio-demographic characteristics were: median age 33 years (men) and 30 years (women); average time since HIV-diagnosis 1 year (men) and 1.5 years (women). Four major themes related to gender inequality emerged:
(1) Men and women fear disclosing HIV-serostatus to partners due to concerns about stigma and relationship dissolution,
(2) Suspicions and mistrust underlie lack of disclosure,
(3) Unequal gender dynamics in relationships influence women's disclosure patterns and result in differential uptake of disclosure among men and women, and
(4) Partial or incomplete disclosure is a strategy to navigate disclosure challenges. Findings illustrate HIV-serostatus disclosure as a complex process evolving over time, sometimes many years, rather than a one-time event.
**Conclusions:** HIV-serostatus disclosure is a critical component of effective HIV prevention. Yet partner communication about HIV-serostatus is infrequent and complicated, with gender inequalities contributing to fear, mistrust and partial or implicit disclosure. Relationship and gender dynamics powerfully impact HIV-serostatus disclosure. Interventions to reduce barriers to effective communication and trust for HIV-serodiscordant couples are needed.

## TUPED310

### #UNDETECTABLE: HIV-POSITIVE. NOT INFECTIOUS

A. Lehner
*Swiss Aids Federation (Aids-Hilfe Schweiz), Program MSM, Zurich, Switzerland*
*Presenting author email: andreas.lehner@aids.ch*

**Background:** People living with HIV stop being infectious if they have been taking effective ART for a certain period. This fact has been widely known since the statement made by the Federal Commission for Aids Issues (EKAF) in 2008. As the “Swiss Statement” it was eagerly discussed at the International Aids Conference in Mexico. Despite this, time and again the debate becomes heated when it is proposed that this message should be incorporated into prevention campaigns. With the #undetectable-campaign, the Swiss Aids Federation, in cooperation with and funded by the Federal Office of Public Health, implements its message into the prevention system of the MSM-population.

**Methods:** The message spread by the campaign reads as follows: “For you as someone with HIV and your partners #undetectable means, that if your viral load has remained below the detectable threshold for at least six months, you take your ART regularly and your doctor also monitors your viral load regularly, you are no longer infectious. #undetectable is a safer sex strategy and is as safe as using a condom. You no longer have to disclose your HIV status if you do not want to. This is an important step toward reducing stigma and discrimination.

**Results:** Eight years after the “Swiss Statement”, the campaign is still causing concerns and bringing up heated discussions among physicians, prevention workers but also PLWHA. By providing training, information and face-to-face discussions, there is a good chance for finally acquiring this shift within the prevention message.

**Conclusions:** #undetectable is one of two big campaigns 2016 targeting the key population of MSM in Switzerland. Ads and informations in print, on social media sites (Facebook, Twitter, Gayromeo, Grindr) and on our website drgay.ch have been published. Peer-to-peer-education, public appearences (at prides, gay venues etc) and lobbying activities targeting the medical system will follow.

## TUPED311

### STRENGTHENED SEXUAL RELATIONSHIPS THROUGH PREP USE BY SERODISCORDANT COUPLES MAY STIMULATE DEMAND FOR PREP IN SUB-SAHARAN AFRICA: QUALITATIVE RESEARCH FROM THE PARTNERS DEMONSTRATION PROJECT

E. Nakku-Joloba[1,2], T.R. Muwonge[3], M.A. Wyatt[4,5], E.T. Katabira[6], N.C. Ware[4,7]
*[1]Makerere University College of Health Sciences, Department of Epidemiology and Biostatistics, Kampala, Uganda, [2]Mulago Hospital, STD Clinic/Ward 12, Kampala, Uganda, [3]Makerere University, Infectious Diseases Institute, Kampala, Uganda, [4]Harvard Medical School, Boston, United States, [5]Harvard Global, Cambridge, United States, [6]Makerere University, Department of Medicine, Kampala, Uganda, [7]Brigham & Women’s Hospital, Boston, United States*
*Presenting author email: edith.nakkujoloba@gmail.com*

**Background:** Plans for rollout of antiretrovirals as pre-exposure prophylaxis (PrEP) are now underway in some sub-Saharan African countries.Demand from populations which stand to benefit from PrEP can fuel the roll-out process. As many as half of new HIV infections in Africa take place in serodiscordant couples. Understanding couples’ experiences of PrEP use can help in developing messages and generating demand for PrEP by HIV serodiscordant couples. Using qualitative data from the Partners Demonstration Project in Kampala, Uganda, we describe serodiscordant couples’ experiences of PrEP use.

**Methods:** We conducted in-depth interviews with 48 serodiscordant couples taking part in the Partners Demonstration Project. Interview topics included: the story of HIV testing and joining the study,experiences of serodiscordance, sexual behavior before and while using PrEP, adherence to PrEP, feelings about PrEP, fertility intentions, and experiences of discontinuing PrEP. Interviews were inductively analyzed to identify themes reflecting couples’ experiences of and responses to PrEP use. Data were classified into categories corresponding to the themes. Together, the categories revealed an important benefit of PrEP use.

**Results:** Learning about HIV serodiscordance creates fear of HIV transmission in couples, who respond by taking steps to manage infection risk - using condoms, reducing sexual frequency and/ or abstaining from sexual relations altogether. These steps make couples feel safer, but also negatively impact their sexual relationship, eroding the quality of sex and interfering with plans to have children. Intimacy and emotional ties between partners are weakened as a result. PrEP is experienced by couples as “added protection” against HIV transmission, creating a safer environment in which to fulfill sexual relationship and reproductive goals. This sense of added protection further reduces fear and offsets damage to sexual relationships caused by other prevention methods.

**Conclusions:** PrEP reduces HIV risk in serodiscordant couples without undermining sexual intimacy and childbearing plans. PrEP’s capacity to prevent HIV transmission without threatening couple’s sexual relationships has the potential to meet needs and stimulate demand for PrEP by serodiscordant couples in sub-Saharan Africa.

## TUPED312

### REACHING AT HARD-TO-REACH POPULATION: AN EFFECTIVE MOBILIZATION OF KEY POPULATION IN NEPAL

D. Joshi, N. Maharjan
*Naya Goreto, TB REACH Project, Lalitpur, Nepal*
*Presenting author email: dipu.joshi799@gmail.com*

**Background:** PLHIV mortality rate to some extent declined with the availability of ART services in Nepal. However, the delay in early diagnosis of Tuberculosis among PLHIV have dramatically contributed to shorting the pre-ART stage on PLHIV; and increase of TB associated death among PLHIV. The HIV prevalence among TB patients is studied, but TB prevalence among PLHIV is still unknown due to rare PLHIV focused TB intervention.

**Description:** Naya Goreto in support of United Nation Office for Project Support (UNOPS) conducted 18 months intensified TB case finding among PLHIV in 10 high HIV prevalence districts of Nepal. Ex-PLHIV/TB co-infected patients were mobilized in project sites for early TB screening, testing and treatment of hard to reach population especially PLHIV, drug users, sex workers and migrant workers. We reached among 8110 (aged 15-64) for early TB diagnosis during the project period including the family members of index cases (TBHIV co-infected). Both active case finding and contact tracing approaches were used primarily, mobilizing PLHIV volunteers with mobile technology to reach hard-to-reach population.

**Lessons learned:** Despite a massive earthquake, project volunteers screened 8110 and found 287 TB cases in hard to reach population; and able to develop a link with key population with health facilities for early access to TB care and support. The mobilization of key population as volunteer is the key reason for extremely satisfied results in short project span. The existing data shows that the present TB prevalence among PLHIV in Nepal is around 4.74.

**Conclusions/Next steps:** The expansion of PLHIV and other vulnerable group focused TB program has had a large and pervasive effect on PLHIV mortality. Improvement in intervention strategies mainly peer groups mobilisation has contributed in early diagnosis of TB among hard to reach population. Only the early TB screening among PLHIV often attributed to timely TB treatment, reducing TB associated death and prolonging pre-ART stage on PLHIV. Therefore, this project has not only provided a baseline data for further operation research; but also forwarded a new approach of meaningful involvement of the key populations in TB Programme of Nepal Government.

# SEXUAL AND REPRODUCTIVE HEALTH, FERTILITY, FAMILY PLANNING AND ABORTION

## TUPED313

### UPSCALING SEXUAL AND REPRODUCTIVE HEALTH AND RIGHTS (SRHR) AMONG YOUNG PEOPLE AND ADOLESCENTS

M. Khumalo[1,2]
*[1]Restless Development Zimbabwe, SRHR and Youth Empowerment, Bulawayo, Zimbabwe, [2]University of South Africa, Department of Development Studies, Pretoria, South Africa*
*Presenting author email: khumalomthandazop@gmail.com*

**Background:** Since the global community is making progress towards 90 90 90 fast track targets by 2020, there is a challenge of ensuring that young people and adolescents receive SRHR quality knowledge and services. In developing countries including rural Zimbabwe, young people and adolescents generally lack sufficient SRHR knowledge and access to services. Restless Development Zimbabwe through the ICS programme in rural areas continues to work on upscaling access to quality SRHR services as well as improved knowledge. The main objectives of the programme were to examine the upscaling of SRHR among young people and adolescents, to increase awareness of SRHR services and information and removing barriers which institutionalise SRHR in order to scale services and ensure full access.

**Methods:** The ICS programme was implemented by both Team Leaders and volunteers who had been recruited in the ICS Programme with the help of Restless Development management. This programme was conducted with 20 000 key populations

**Tuesday 19 July** Poster Exhibition

Wednesday 20 July

Thursday 21 July

Friday 22 July

Late Breaker Posters

Author Index

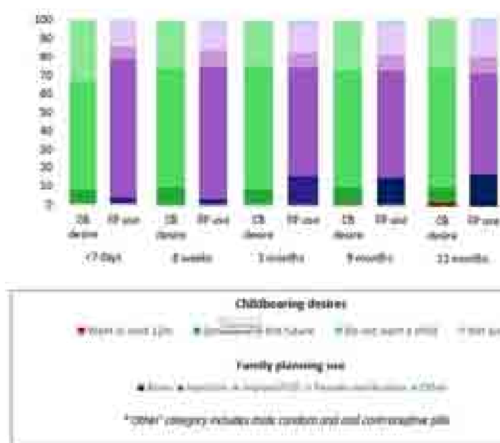
which comprised of young people and adolescents who received SRHR knowledge and access to services between August 2015 to November 2015 in rural Zimbabwe, Bulilima District. Well planned SRHR and HIV/AIDS education interventions were implemented. A rights based approach was adopted as it specifically centred on the health and well being of young people and adolescents. The programme also conducted full stakeholders' involvement of community leaders and other stakeholders working towards the same scope of Restless Development.
**Results:** SRHR education interventions have been found to increase knowledge as well as develop life skills in order to change risky behaviours. Of the 20,000 key populations, 90 % reported behaviour change and also reported to have both received SRHR knowledge and services in clinics and schools whilst the remaining 10% received SRHR services and quality information. Full stakeholders' involvement was also active through participation of community leadership in caucus meetings and campaigns.
**Conclusions:** Upscaling of SRHR results in high behaviour change communications, it also lessens levels of teenage pregnancy as well as reducing HIV infections and deaths among young people and adolescents. Great improvements have been achieved although vast efforts are still needed such that 2020 Fast Track Targets are met.

## TUPED314

### CHILDBEARING INTENTIONS AND FAMILY PLANNING UPTAKE IN HIV+ WOMEN ON ANTIRETROVIRAL THERAPY (ART) IN THE POSTPARTUM PERIOD

C.A. Towriss[1,2], E.J. Abrams[3], T. Phillips[2,4], J.A. McIntyre[2,5], L. Myer[2,4]
*[1]University of Cape Town, Centre for Actuarial Research, Cape Town, South Africa, [2]University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa, [3]Columbia University, ICAP, New York, United States, [4]University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [5]ANOVA Health Institute, Johannesburg, South Africa*
*Presenting author email: catriona.towriss@uct.ac.za*

**Background:** There are growing concerns about the childbearing intentions and family planning (FP) needs of women on ART, yet little is known about these issues in HIV+ women during the postpartum period. We examined childbearing intentions and FP uptake among HIV+ women during the first year postpartum in Cape Town, South Africa.
**Methods:** We followed 471 women on ART from delivery through 12 months postpartum between June 2013-June 2015. In up to 5 interviews conducted separately from routine health services, women reported on FP use and childbearing intentions; the latter was recorded using a 4-point scale measuring perceived future desires, categorised as
(i) unsure,
(ii) definitely do not want to become pregnant in the future,
(iii) may want to become pregnant in the future,
(iv) definitely do want to become pregnant in the next 12 months.
**Results:** In this population (median age, 29; 42% married/cohabiting), childbearing intentions remained stable throughout the postpartum period: across visits, 90-92% of women were unsure or definitely did not want to become pregnant in the future (Figure 1). Desire to become pregnant in the next 12 months was reported in < 2% of women consistently over time. In contrast, the proportion of women not using FP increased, from 4% to 17% by 12 months postpartum; these increases were driven by discontinuation of injectables. Use of implants and intrauterine devices (IUDs) increased over time (14-19%). Among women at 12 months postpartum who were unsure or definitely did not want to become pregnant in the future, 18% were not using FP.



*[Figure 1: Childbearing desires and family planning method use by post-partum duration]*

**Conclusions:** Non-use of FP increases over the postpartum period among HIV+ women. Discontinuation of injectables contributes to non-use. While further research into the determinants of childbearing intentions and FP use are needed in this population, long-acting methods suitable for women using ART, such as the IUD require ongoing programmatic support.

## TUPED315

### CONTRACEPTIVE USE AMONG WOMEN LIVING WITH HIV AND AIDS RECEIVING CARE AT SECONDARY AND TERTIARY HEALTH FACILITIES IN IBADAN NIGERIA

F.A. Adenuga, A.S. Bakarey, M.B. Titiloye, Women living with HIV and AIDS
*College of Medicine, University of Ibadan, Obstetrics and Gynaecology, Ibadan, Nigeria*
*Presenting author email: dasfadolad@gmail.com*

**Background:** Contraceptive use is a form of family planning and it is one practice among the most important health decisions that many people including women living with HIV and AIDS. Inadequate information on available contraceptive methods and restriction of choices are major constraints for contraceptive users to obtain a method that suits their unmet need. Hence, this study was designed to assess the contraceptives use among HIV positive women receiving care at secondary and tertiary health facilities in Ibadan. Nigeria
**Methods:** A cross-sectional study using systematic random sampling technique was conducted to select 350 consenting women among HIV positive women receiving care in two health facilities in Ibadan. A pre-tested interviewer-administered questionnaire which contained respondents' Socio-demographic characteristics, unmet need of contraceptive use, family planning method used and their effectiveness, experience and level of satisfaction of modern contraceptive use was adopted.
**Results:** Age of the respondents was 37.0$\pm$8.5, 87.0% were married and 68.0% were in monogamous marriage. Respondents with Junior and Senior Secondary School certificates were 41.1% and 34.3% rates respectively. Analysis by unmet need revealed that about 97.0% of the women had had at least one birth, 46.0% of the women had 4-6 previous pregnancies, 44.0% had 1-3 pregnancies while 7% had more than 6 previous pregnancies. Current method of contraception was influenced by joint agreement with their spouses (33.0%), Condom was the commonest choice (54.8%) followed by Oral pills (20.1%) while Injectables (16.1%) IUCD (10.5%) and Implants (9.5%) were the least common choices respectively. Of the women that encountered problems, 54.0% indicated they would seek solution from providers, 15.0% would adopt traditional methods, 12.0% would change method while about 4.0% don't know what to do. Factors influencing continuation of chosen method included (39.7%), availability (24.1), Affordability (14.1%) and effectiveness (13.1%). A major reason for being satisfied with chosen method was adequate information before choice (94.5%).
**Conclusions:** High level of education and previous use of contraceptives supported by spouses are factors influencing modern contraceptive choices. Family planning programme should be incorporated as a component part of care for women living with HIV and AIDS.

## TUPED316

### A COMPARISON OF SEXUAL BEHAVIOR AMONG OLDER ADULTS WITH HIV FROM SOUTH AFRICA AND UGANDA: FINDINGS FROM THE RESEARCH ON OLDER ADULTS WITH HIV (ROAH) AFRICA PROJECT

M. Brennan-Ing[1,2], K. Porter[1], C. MacPhail[3], J. Seeley[4], V. Minichiello[5], S. Karpiak[1,2], F. Venter[6], M. Kuteesa[4], L. Geddes[7], J. Negin[8]
*[1]ACRIA, Center on HIV and Aging, New York, United States, [2]New York University, College of Nursing, New York, United States, [3]University of New England, Armidale, Australia, [4]MRC Uganda Viral Research Institute, Uganda Research Unit on AIDS, Entebbe, Uganda, [5]University of Newcastle, School of Medicine and Public Health, Callaghan, Australia, [6]University of Witwatersrand, Johannesburg, South Africa, [7]University of New South Wales, The Kirby Institute, Sydney, Australia, [8]University of Sydney, Sydney, Australia*
*Presenting author email: mbrennan@acria.org*

**Background:** As antiretrovirals become more widely available in sub-Saharan Africa, the population of adults 50 and older with HIV will continue to grow and is currently estimated at over 3,000,000. We know little about this burgeoning group, including levels of sexual activity and risk behaviors that could inform HIV prevention efforts. Such data are needed as research finds adults remain sexually active into old age, providing a vector for HIV and other STI transmission.
**Methods:** Data were obtained from ROAH Africa sites in Uganda (UG) and South Africa (SA) on adults 50 and older with HIV from 2013 to 2015. In UG (N = 101), 58% were women and the average age was 61 years. In SA (N = 108), 72% were women

and the average age was 58 years. Questions on sexual activity were adapted from the National Social Heath and Aging Project (Lindau et al., 2007), and significant differences were examined using Fisher's Exact Tests.
**Results:** SA older adults were significantly more likely to report sexually activity in the past year (51%) compared to UG (31%), and men were the most active in both countries. SA older adults were more likely to report becoming HIV-infected from a spouse (57%) vs. a casual partner (31%), but in UG these vectors were nearly equivalent (43% and 41%, respectively). HIV disclosure between partners in UG was significantly greater compared with SA (ranges 93-96% and 70-80%, respectively), and greater in UG compared with extant research on younger samples. However, SA older adults were significantly more likely to report condom use usually/always with spouses and casual partners (92% and 93%, respectively) compared to UG (33% and 50%, respectively).
**Conclusions:** Older adults with HIV in both UG and SA remain sexually active, underscoring the need for secondary HIV prevention efforts directed at the older population. Data on differences in condom use suggest such efforts could be successful in regions where condom uptake could be improved. Differences between SA and UG older adults in sexual activity suggest that cultural and social influences preclude making broad generalizations about older adults with HIV on the African continent.

## TUPED317

### MISSED OPPORTUNITIES FOR SEXUAL AND REPRODUCTIVE HEALTH COUNSELING FOLLOWING HIV DIAGNOSIS IN KWAZULU-NATAL, SOUTH AFRICA

A. Gandhi[1], N. Lince-Deroche[2,3], J. Mantell[1], S. Tariq[4], T. Exner[1], K. Blanchard[5], G. Ramjee[6], S. Hoffman[1,7]
*[1]Columbia University and New York State Psychiatric Institute, HIV Center for Clinical and Behavioral Studies, New York, United States, [2]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Department of Internal Medicine, Johannesburg, South Africa, [3]Ibis Reproductive Health, Johannesburg, South Africa, [4]University College London, Research Department of Infection and Population Health, London, United Kingdom, [5]Ibis Reproductive Health, Cambridge, United States, [6]South African Medical Research Council, HIV Prevention Research Unit, Durban, South Africa, [7]Mailman School of Public Health, Columbia University, Department of Epidemiology, New York, United States*
*Presenting author email: sh51@cumc.columbia.edu*

**Background:** Post-diagnosis counseling presents a key opportunity for providers to help newly-diagnosed HIV+ individuals adjust to their diagnosis and promote their health and well-being. Integrating sexual and reproductive health information into HIV-related counseling sessions is recommended in South Africa's national guidelines, but few have examined whether such messages are included, or how they are received.
**Methods:** We conducted serial semi-structured interviews over an eight-month period in 2012-2013 with a targeted subsample of 13 women and 13 men from *Pathways to Care*, a prospective cohort study of newly-diagnosed HIV+ adults recruited from three public primary care clinics in KwaZulu-Natal. At each interview, participants were asked what counseling messages they had received about leading a healthy lifestyle, sexual behavior, contraception, safe conception, and pregnancy termination options. Audio-recorded interviews were translated, transcribed, and analyzed thematically in NVivo 10.0.
**Results:** All participants reported receiving sexual risk reduction messaging at some point during post-diagnosis counseling. Dominant counseling messages included discouraging concurrent sexual partnerships, and encouraging consistent condom use and having less sex overall. However, some participants misunderstood or were misinformed about reasons for condom use; a minority believed that engaging in condomless intercourse could directly lower their CD4+ count or increase viral load. Half of the participants had not received any counseling regarding family planning options beyond condoms, or about safe conception options if they desired children in the future. No participants reported receiving counseling regarding how to terminate an unwanted pregnancy.
**Conclusions:** Sexual and reproductive health counseling appeared to be incomplete and inconsistent in our sample of newly-diagnosed HIV+ men and women. This indicates a missed opportunity to enhance the quality of life for persons living with HIV, and underscores the need to allocate additional resources so that HIV counselors are sufficiently trained and supported to provide basic sexual and reproductive health information and relevant referrals to their clients.

## TUPED318

### TRENDS AND PREDICTORS OF LIVE-BIRTH AND ABORTION RATES AMONG HIV-INFECTED AND -UNINFECTED WOMEN ENROLLED IN THE WOMEN'S INTERAGENCY HIV STUDY (WIHS): 1994-2012

L. Haddad[1], K. Wall[2], C.C. Mehta[3], E. Golub[4], L. Rahangdale[5], M.-C. Kempf[6], R. Karim[7], R. Wright[8], H. Minkoff[9], M. Cohen[10], S. Kassaye[11], D. Cohan[12], I. Ofotokun[13], S.E. Cohn[14]
*[1]Emory University School of Medicine, Department of Gynecology and Obstetrics, Atlanta, United States, [2]Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States, [3]Emory University Rollins School of Public Health, Department of Biostatistics and Bioinformatics, Atlanta, United States, [4]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [5]University of North Caroline School of Medicine, Department of Obstetrics and Gynecology, Chapel Hill, United States, [6]University of Alabama at Birmingham School of Nursing, Department of Health Behavior and School of Public Health, Birmingham, United States, [7]University of Southern California Keck School of Medicine, Department of Pediatrics and Preventative Medicine, Los Angeles, United States, [8]Albert Einstein College of Medicine, Department of Obstetrics and Gynecology, Bronx, United States, [9]Maimonides Medical Center, Department of Obstetrics and Gynecology, Brooklyn, United States, [10]CORE Center/Division of Infectious Diseases, John H. Stroger Jr. Hospital of Cook County, Chicago, United States, [11]Georgetown University School of Medicine, Department of Medicine, Division of Infectious Diseases and Travel Medicine, Washington DC, United States, [12]University of California, School of Medicine, Department of Obstetrics and Gynecology, San Francisco, United States, [13]Emory University School of Medicine, Department of Medicine, Division of Infectious Diseases, Atlanta, United States, [14]Northwestern University Feinberg School of Medicine, Department of Medicine, Division of Infectious Diseases, Chicago, United States*
*Presenting author email: lbhadda@emory.edu*

**Background:** Little is known about fertility choices and pregnancy outcome rates among HIV-infected women in the current combination ART era. We describe trends and predictors of live-birth and abortion rates between 1994 and 2012 in women enrolled in the WIHS.
**Methods:** We analyzed longitudinal data collected from October 1st 1994 to September 30th 2012 through WIHS, a multicenter prospective cohort study of HIV-infected and HIV-uninfected women in the U.S. Rates per 100 person-years for self-reported induced abortions and live-births were determined over 4 time periods, with standardized time interval adjustment for age by sero-status. Adjusted incidence rate ratios for live-births and abortions with 95% confidence intervals were obtained using a Poisson mixed effects model to evaluate multivariate associations including variables significant for either HIV sero-status by univariate association (< 0.10).
**Results:** There were 1,356 pregnancies among 2,414 women included in this analysis. Among HIV-infected women, the age-adjusted rates of live-birth increased from 1994-1997 to 2006-2012 (2.85/100PY to 7.27/100PY), while age-adjusted rates of abortion remained stable (4.03/100PY to 4.29/100PY). Significantly lower live-birth rates occurred among HIV-infected compared to uninfected women in 1994-1997 and 1997-2001, however rates were similar for later time intervals of 2002-2005 and 2006-2012. Among HIV-infected women, older age (>35 vs < 25 IRR 0.14 (0.08-0.23)), CD4+ counts < 350 cells/mm$^3$ (IRR 0.72 (0.53, 0.97)), any condom use during prior 6 months (IRR 0.73 (0.56-0.97)) and alcohol use (>=7 drinks/week IRR 0.47 (0.22, 0.97)) was associated with reduced live-birth rates. There was a trend towards increased live-birth rates among ART users (IRR 1.35 (0.99, 1.83)). Abortion rates were lower among older women and those with prior sexually transmitted infections, and higher among those from the Brooklyn site, condom users, with higher parity, and prior abortion. Use of ART, CD4+ count, and viral load were not associated with abortion rates. Contraceptive use was not associated with either outcome.
**Conclusions:** Unlike earlier periods when pregnancy and live-birth rates were low among HIV-infected women, rates are now similar to uninfected women in the WIHS, potentially due to improved health status with ART. However, abortion rates are unchanged indicating an ongoing opportunity to improve family planning services.

## TUPED319

### PUBLIC INTEREST LITIGATION TO CHALLENGE THE FORCED AND/OR COERCED STERILIZATION OF WOMEN LIVING WITH HIV

T. Saoyo
*Kenya Ethical and Legal Issues Network on HIV and AIDS, Nairobi, Kenya*
*Presenting author email: tsaoyo@kelinkenya.org*

**Background:** In many African contexts, motherhood informs social constructions of womanhood and femininity. Forced and/or coerced sterilization of women living with HIV (WLHIV) robs women their right to choose to have children. Sterilized

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July

Author Index

women face extreme stigma, gender-based violence, abuse from their communities, and a loss of their status as "whole" women. International bodies have convened to strategize on the relationship between such human rights abuses and the key legal questions pertaining to the global AIDS response. In this vein, UNDP coordinated a strategy meeting in 2015 to discuss the findings of the Global Commission on HIV and the Law's regarding young women and adolescent girls. Contributing to the advancement of these recommendations, the Kenya Legal and Ethical Issues Network on HIV & AIDS (KELIN) is engaged in facilitating access to justice through the legal representation of women who have been forced or coerced into sterilization.

**Description:** With a view toward the full enjoyment of health-related rights, KELIN provides legal services and influences policy that promotes evidence-based change. Through public interest litigation, KELIN advocates for the enjoyment of health on a more far-reaching scale than with individual cases. With the support of partners, KELIN is challenging the sterilization of women living with HIV - representative of a larger cohort of victims - in two currently ongoing court cases initiated in 2014.

**Lessons learned:** Women's narratives have revealed that illegitimate consent and a lack of awareness of rights are at the core of sterilization, revealing a discrepancy between laws/policies and actual practices. Other lessons include the important impacts of community-led documentation and sensitization, alliance building, and lobbying at a high-level, policy level.

**Conclusions/Next steps:** Education and empowerment on reproductive health rights will be instrumental in tackling misinformation by healthcare providers. Key next steps include continuous training of WLHIV, their families, and healthcare providers. The public interest litigation itself has the potential to set a legal precedent in Kenya and hold the government accountable in the long term.

## TUPED320

### UNDERSTANDING CONTRACEPTIVE USE AND PRACTICES AMONG FEMALE SEX WORKERS LIVING WITH HIV IN THE DOMINICAN REPUBLIC

D. Cernigliaro[1,2], C. Barrington[3], M. Perez[4], Y. Donastorg[4], D. Kerrigan[1]
*[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]New York University- Lutheran, New York, United States, [3]University of North Carolina, Gillings School of Global Public Health, Chapel Hill, United States, [4]HIV Vaccine Research Unit. Instituto Dermatalógico y Cirugia de Piel Dr. Humberto Bogart Diaz, Santo Domingo, Dominican Republic*
*Presenting author email: danacern@gmail.com*

**Background:** Female sex workers (FSW) living with HIV are at increased risk for unintended pregnancy, abortion, pregnancy complications and other negative health outcomes, yet little is know about the contraceptive practices of this population.

**Methods:** Data was analyzed on 268 current FSW living with HIV in the Dominican Republic. Descriptive analysis was conducted to understand varied methods of contraceptive use and practices in this population.

**Results:** About 95% of participants reported at least one pregnancy (mean: 4.2; range: About 80% (216/268) of participants reported using at least one form of contraceptive method (barrier or non-barrier) in the last 6 months. Consistent condom use was about 73% (197/268) on average with all clients, however condoms are used more consistently with new (190/214; 88.79%) and regular clients (217/248; 87.50%) as compared to steady partners (152/228; 66.67%). For those using non-barrier contraceptive methods, most (134/267; 50%) reported a permanent procedure with the high majority reporting a tubal ligation (47.39%) as compared to hysterectomy (3.73%). The average age of the permanent contraceptive procedure was 28 with a broad age range (15 to 45 years). Just under a third (36/127; 28.34%) of participants reported having the procedure within 3 years of their HIV diagnosis. About a third or participants who have had a permanent procedure reported that they would like more children. Of those who reported not using any method to prevent pregnancy (barrier or non-barrier) in the last 6 months (18.90%), about 66% of those participants also indicated not wanting more children.

**Conclusions:** The results of this analysis highlights the importance of further research on contraceptive use and FSW living with HIV. For a population facing barriers to care and at high risk for unintended pregnancy, STI, and transmission of HIV, integrated care and a better understanding of both HIV and reproductive health needs is important. Further research is needed to understand dynamics surrounding contraceptive decision-making and health provider communication surrounding family planning and pregnancy.

## TUPED321

### FACTORS ASSOCIATED WITH THE DESIRE FOR FUTURE CHILDREN AMONG HIV-POSITIVE WOMEN AND MEN IN MALAWI

J.W. Krashin[1], L.B. Haddad[2], H. Tweya[3], J. Chiwoko[3], W. Ng'ambi[3], B. Samala[3], T. Chaweza[3], J.H. Tang[1,4], M. Hosseinipour[4,5], S. Phiri[3,5]
*[1]University of North Carolina School of Medicine, Department of Obstetrics & Gynecology, Chapel Hill, United States, [2]Emory University School of Medicine, Department of Gynecology and Obstetrics, Atlanta, United States, [3]The Lighthouse Trust, Kamuzu Central Hospital, Lilongwe, Malawi, [4]UNC Project Malawi, Kamuzu Central Hospital, Lilongwe, Malawi, [5]University of North Carolina School of Medicine, Department of Medicine, Chapel Hill, United States*
*Presenting author email: lisa.haddad@emory.edu*

**Background:** The objective of this analysis was to identify factors related to the desire to have children in the future among HIV-positive patients in Malawi and to describe the contraceptive methods used among those desiring no future children.

**Methods:** We conducted a cross-sectional questionnaire of reproductive health knowledge, attitudes and practices among patients receiving care at two large public HIV clinics in Lilongwe, Malawi between September and December 2013. Our primary outcome was the desire to have children in the future. We used descriptive statistics to describe contraceptive pattern use and Poisson regression to estimate adjusted prevalence ratios (aPRs) for factors associated with the desire to have children in the future.

**Results:** Among 308 female and 250 male participants, most received antiretroviral therapy, were in long-term relationships, and had at least one living child. One-third of participants desired future pregnancy. Approximately 80% of participants who did not want children in the future reported using contraception at last intercourse; the most frequently used methods were depot medroxyprogesterone acetate (28.2% of women; 17.8% of men) and condoms (19.8% of women; 43.9% of men). Long-acting reversible contraceptive methods (LARC: intrauterine contraception and implants) were infrequently used. Among men, factors associated with desiring future children were having a partner who wanted children (aPR 4.60, 95% CI 2.94-7.18) and having four or more children compared to zero to one child (aPR 0.41, 95% CI 0.24-0.70). Among women, factors associated with the desiring future children were having a partner who wanted children (aPR 4.17, 95% CI 2.69-6.47), lower parity (aPR 0.45, 95% CI 0.26-0.77, four or more children compared to zero to one child), and believing pregnancy was healthy for her (aPR 1.65, 95% CI 1.24-2.18).

**Conclusions:** Many HIV-positive men and women desire future children, and targeted counseling on safe conception can optimize health outcomes for these individuals and their families. Our findings help guide counseling and show areas for improvement in reproductive life planning for HIV-positive patients in Malawi. Increasing use of the most effective methods, specifically LARC, for patients who do not want future children may reduce unintended pregnancies in this population.

## HIV AND THE WORKPLACE: DISCRIMINATION, UNEMPLOYMENT, RETURN TO WORK AND REHABILITATION

## TUPED322

### PROCESSES OF RESILIENCE AMONG PEOPLE LIVING WITH HIV/AIDS SEEKING VOCATIONAL REHABILITATION: A QUALITATIVE APPROACH

W. Gómez[1], A. Schustack[2], A.W. Carrico[3]
*[1]University of California, School of Social Welfare, Berkeley, United States, [2]Positive Resource Center, San Francisco, United States, [3]University of California, School of Nursing, San Francisco, United States*
*Presenting author email: wgomezjr@berkeley.edu*

**Background:** Vocational rehabilitation among people living with HIV/AIDS (PLWHA) remains an understudied subject. While research has shown that stressors related to unemployment negatively affect the quality of life of PLWHA, little has been done to understand and explain the nuances of this relationship. Although resilience has become a fixture in the field of HIV/AIDS in the past decade, its role tends to be limited to that of a protective psychological factor and/or as a buffer to traumatic experiences. This exploratory qualitative study sought to reframe resilience as a series of processes that could facilitate prosocial behaviors toward vocational rehabilitation, in particular among long-term HIV/AIDS survivors.

**Methods:** Our data was collected between 2011and 2012 in San Francisco, CA. These data originated from a cohort of 108 PLWHA who had recently accessed vocational rehabilitation services. We purposively sampled 22 participants based on time since HIV diagnosis and self-reported social standing. We employed a grounded theory approach to develop themes relevant to the study and utilized Atlas.ti to analyze transcripts of semi-structured qualitative interviews.

**Results:** Our sample's mean age is 43 (SD = 9.9), 55% are Caucasian and 68% are male. The data revealed eight major domains that exemplified processes related to resilience within this sample. When stratifying by age, the data showed thematic differences between participants over 40, and those under. Among those over 40, the data elucidated engagement in processes of resilience geared toward *Renegotiating Identities* and *Reframing Negative Events*, while those under 40 were more likely to endorse processes around *Accessing Networks* and *Managing Resources*. The resilient behaviors for participants over 40 seem to be cemented in manifestations of cultural capital, whereas their counterparts under 40 were more adept to invoke social capital and as a means to resilience. Both groups made reference to *Goal Setting* behaviors, which seems to have facilitated engagement in vocational rehabilitation.
**Conclusions:** These data underscore important issues related to identity formation, social networks and other markers of resilience relevant to the vocational rehabilitation efforts of PLWHA. Moreover, harnessing these features through a strengths-based framework could prove imperative to health-related efforts for this population.

## LIVING WITH HIV AND CO-INFECTIONS AND/OR CO-MORBIDITIES

### TUPED323

#### IDENTIFYING TB-HIV CO-INFECTION: A COMMUNITY-LED MODEL FOR TUBERCULOSIS SCREENING AMONG PLHIV: EXPERIENCE FROM THE VIHAAN PROGRAMME IN INDIA

M. Balani[1], V. Arumugam[2], R. Huidrom[1], S. Mehta[3], J. Robertson[4]
*[1]India HIV/AIDS Alliance, Program, Delhi, India, [2]India HIV/AIDS Alliance, Strategic Information, Delhi, India, [3]India HIV/AIDS Allaince, Program and Policy, Delhi, India, [4]India HIV/AIDS Alliance, Delhi, India*
*Presenting author email: monabalai1@gmail.com*

**Background:** The estimated number of people living with HIV in India is 2.1 million (NACO), of which 95,000 are co-infected with tuberculosis (TB). There is a huge coordination gap between the national HIV and TB programmes, and high mortality among those cases with HIV-TB co-infection. Chances of latent TB developing into active TB are high among PLHIV in India. The Global Fund-supported Vihaan programme, implemented by India HIV/ AIDS Alliance and partners, puts special emphasis on HIV-TB integration and care and support for the co-infected.
**Description:** Vihaan promotes treatment adherence as one of the major objectives of the 350 Care & Support Centres (CSCs) across India. 80% of CSCs are implemented by District Level Networks of PLHIV. Intensive Case Finding (ICF) of PLHIV also living with TB is an essential activity carried out by the CSCs, which is done following an assessment protocol. ICF is based on four major symptoms: cough for any duration, weight loss, fever and presence of night sweats. PLHIV found to have any of one of the common symptoms are referred to TB testing centres. Clients diagnosed with TB are then linked with TB treatment facilities. 55,582 PLHIV were screened for TB, of which 9,499 were referred for testing. Of them, 762 PLHIV were diagnosed with TB within the initial three-month period of ICF in 2015.
**Lessons learned:** Community-led model for screening TB through the use of ICF has proven to be effective. CSC outreach workers (ORWs) and peer counsellors are from the PLHIV community and are well suited to facilitate early diagnosis and linkages for TB testing and treatment, as well as support individual case management. ICF is convenient and easy-to-use for outreach workers, and enables identification of symptomatic clients.
**Conclusions/Next steps:** Integrating TB screening with HIV care & support services using the ICF strategy has resulted in an increase in the early diagnosis of co-infection, thus facilitating better health management among PLHIV. This strategy is being further scaled up to reach all 1.2 million PLHIV who will be registered under the Vihaan programme.

### TUPED324

#### EFFECTIVENESS OF SMOKING CESSATION PROGRAM FOR PRISONERS LIVE WITH HIV/AIDS

F. Jalali, A. Hasani, A. Babaei
*Educational and Research Centre, District XI of State Prisons, Mashhad, Iran, Islamic Republic of*
*Presenting author email: farjalali@gmail.com*

**Background:** Cigarette smoking is a global public health problem. The prevalence of cigarette smoking is higher in HIV positive patients as compared to the general population. Moreover,smoking prevalence is high in prisoners. HIV-positive patients who smoke, have significantly increased mortality and morbidity compared to those who have neversmoked. In this regard, we evaluated effectiveness of smoking cessation program for prisoners live with HIV/AIDS.
**Methods:** The study was designed as a double-blind, randomized, controlled clinical trial, and it began in February 2014 and ended in February 2015. 36 prisoners met the inclusion criteria and were enrolled in the study. They were divided randomly into three groups, i.e., MI-based treatment, MI with NRT, and the control group, which didn't receive any therapy. The outcome measures were reported after intervention and at a 90-day follow-up, and changes in the CO levels in expired air and nicotine dependency were measured.
**Results:** The average age of the subjects was 32.59 ± 4.76, and their mean duration of imprisonment was 4.3 ± 1.90 years. They smoked an average of 22.84 ± 8.72 cigarettes per day. Analysis of the concentration of CO in expired air in the pre-test, post-test, and at the follow-up for the three groups showed that the variations in the mean CO concentrations in the MI group and the MI with NRT group at the pre-test and at the post-test were statistically significant ($p < 0.001$), but no significant changes occurred between the post-test and the follow-up ($p > 0.050$). In addition, the results indicated that CO concentration in expired air in the MI with NRT group was statistically significant, with better efficacy of smoking cessation, compared with control group and the MI group after the follow-up ($p = 0.02$).
**Conclusions:** Smoking cessation may be more difficult for people living with HIV because they are often also coping with mental health and substance use issues. As a result, less intensive interventions such as giving advice may not be enough. Some may benefit from more intensive interventions such as repeated counselling, nicotine replacement and psychiatric assistance.

## CONCEPTUALIZING SOCIAL AND STRUCTURAL FACTORS AND THEIR IMPACTS

### TUPED325

#### SOCIO-CULTURAL FACTORS INFLUENCING ADHERENCE TO ANTIRETROVIRAL THERAPY AMONG HIV PATIENTS IN A UNIVERSITY TEACHING HOSPITAL IN SOUTH-WEST NIGERIA

O. Okunola[1], C.O. Muoghalu[2], A.I. Irinoye[3]
*[1]Obafemi Awolowo University Health Center, Medical and Health Services, Ile-Ife, Nigeria, [2]Obafemi Awolowo University, Sociology and Anthropology, ile-ife, Osun state, Nigeria, [3]Obafemi Awolowo University Health Center, Medical and Health Services, ile-ife, osun state, Nigeria*
*Presenting author email: oaokunola@oauife.edu.ng*

**Background:** The objectives are to examine the perception of people living with HIV/AIDS of antiretroviral therapy in the study area, investigate the influence of socio-cultural factors on adherence to treatment regimen in the study area and assess the prevalence of adherence to ART among PLWHA in the study area.
**Methods:** A cross-sectional study design where both qualitative and quantitative research methods were adopted. Participants were HIV diagnosed patients attending clinic at the Hospitals Complex in Ile-Ife between the ages of 18 to 60 years. Three healthcare delivery personnel working in the clinic were interviewed. Using Fischer's formula 336 patients living with HIV were selected for the study. Participants had been on antiretroviral drugs for more than six months prior to the study . Two focus group discussion sessions comprising of 10 male and 10 female living with HIV and currently on ART were conducted. These groups were purposively selected based on their being on ART for more than one year. In-depth interviews were conducted among three purposively selected healthcare givers (an experienced nurse, a doctor and a pharmacist) working in this clinic. Data were collected using a structured questionnaire, an interview guide and tape-recorder. Quantitative data were analysed with descriptive and inferential statistics. Content analysis was used to analyse responses from IDI and FGD.
**Results:** The study revealed positive perception to ART among PLWHA of about 86.3% ,the level of adherence to ART was 89.0% . A strong relationship exists between social and family supports and the degree of adherence to ART . Nutrition, polygamy, difficulty in financing transportation fare to the clinic, unemployment, drug hawkers, religion, excuse duty from work and waking up very early were highlighted as barriers to adherence to ART. Fear of death, strong family support, religion belief, not seeking alternative treatment, absence of rituals and perceived improved health status were noted as facilitators to adherence.
**Conclusions:** It was concluded that to achieve optimal outcome in the management of HIV various social and cultural contexts should be taken into consideration . This study was able to ascertain the influence of these various factors militating and facilitating adherence to ART.

## TUPED326

### CONCEPTUALIZING "TRANSACTIONAL SEX" IN SUB-SAHARAN AFRICA: A REVIEW AND SYNTHESIS OF THE LITERATURE

K. Stoebenau[1], L. Heise[2], J. Wamoyi[3], N. Bobrova[4]
*[1]American University, Center on Health, Risk and Society, Washington, DC, United States, [2]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom, [3]National Institutes of Medical Research, Mwanza, Tanzania, United Republic of, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom*

**Background:** In sub-Saharan Africa, young women ages 15 -24 have more than twice the risk of acquiring HIV as their male counterparts. A growing body of epidemiological evidence suggests that the practice of 'transactional sex' may contribute to this disparity. Over the last 15 years, the social sciences have contributed significantly to the understanding of the meaning and motivations for this practice. The findings from these studies are rich, but present conflicting narratives, rendering lessons difficult to navigate for intervention and further research.
**Methods:** We contribute a historically-grounded, comprehensive literature review on the nature and motivations for women's participation in transactional sex in sub-Saharan Africa. Using systematic review approaches, we found 310 studies that fit our search criteria. We identified 11 themes in a data extraction matrix that we used to code articles in qualitative research software (Atlas/ti 7). We then further distilled three dominant paradigms on transactional sex that we review toward presenting a unified conceptualization of the practice.
**Results:** The first paradigm "the vulnerable victim who practices sex for basic needs" positions women as victims in transactional sexual relationships, with implications for interventions that protect girls from exploitation. In direct contrast, the "sex for upward mobility" paradigm positions women as sexual agents who engage in transactional sex toward attaining a middle class status and lifestyle. Finally, a third paradigm "sex for material expressions of love," draws attention to the intimacy of love and money, and the central role of men as providers in relationships. We find important commonalities in the structural factors that shape the three paradigms on transactional sex including gender inequality and processes of economic change. We suggest that there are three continuums stretching across these paradigms: those of emotionality, agency and deprivation.
**Conclusions:** This review holds implications for research and interventions, and can serve as a basis for improved efforts to identify pathways through which transactional sex increases young women's risk of HIV. We discuss the consequences of drawing from too narrow an understanding of the practice, and the need to acknowledge continuums of agency and emotionality in intervention approaches.

## TUPED327

### MASCULINITY, INTERNALIZED HETEROSEXISM, AND OTHER PSYCHOSOCIAL HEALTH PROBLEMS: TOWARD A GENDERED MODEL OF HIV SEXUAL RISK PROCESSES IN GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN

T.L. Brown, N.G. Smith, J. Cox
*McGill University, Montreal, Canada*
*Presenting author email: tyler.brown@mail.mcgill.ca*

**Background:** *Internalized heterosexism* (IH) occurs when gay, bisexual, and other men who have sex with men (GBMSM) internalize negative societal attitudes toward their own sexuality. IH has often been used to explain why GBMSM are at increased risk of contracting HIV. However, meta-analysis has revealed that the association between IH and HIV sexual risk behavior in GBMSM is generally small and has decreased over time (Newcomb & Mustanski, 2011). Although these findings challenge the usefulness of IH in HIV research, theory and research from the psychology of men and masculinity may offer a context for IH's continued use. Furthermore, this context may warrant a new "gendered" model of HIV sexual risk processes in GBMSM.
**Description:** The goal of the current project was to provide a brief summary of the potential impact of masculinity on HIV sexual risk behavior in GBMSM to support the development of a multivariate model of HIV sexual risk processes in GBMSM based on The New Psychology of Men using The Gender Role Strain Paradigm as a framework. A comprehensive review of the literature using PsycInfo key terms including Masculinity, Gender Identity, Male Homosexuality, and HIV was conducted.
**Lessons learned:** The present review supports the model that IH may have both direct and indirect (through psychosocial health problems) effects on HIV sexual risk, but that these effects of IH on HIV sexual risk may be moderated by psychological concepts of masculinity. That is, the effects of IH on HIV sexual risk are conditional, depending on the degree of endorsement of psychological concepts of masculinity. There are three locations within the proposed model where psychological concepts of masculinity may serve as a moderator: the direct effect of IH on sexual risk, the effect of IH on psychosocial health problems, and the effect of psychosocial health problems on HIV sexual risk.
**Conclusions/Next steps:** The next step is to test the model using conditional process analysis. If findings support the model, a masculinity based HIV prevention intervention will then be designed and tested.

## TUPED328

### THE PANADO PROBLEM: MEDIATING HEALTH AND HIV SERVICE PROVISION IN THE COMMERCIAL AGRICULTURAL SECTOR - A STUDY OF EMPLOYER ATTITUDES AND PRACTICES IN TWO DISTRICTS IN SOUTH AFRICA

N. Pillay[1,2], N. Coulson[1,2], C. du Preez[3]
*[1]Sarraounia Public Health Trust, Research, Johannesburg, South Africa, [2]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [3]Hlokomela Training Trust, Hoedspruit, South Africa*
*Presenting author email: dupreezjc@worldonline.co.za*

**Background:** HIV prevalence amongst farmworkers in parts of Limpopo and Mpumalanga provinces in South Africa is twice that of the local district despite the provision of government clinic and mobile health services, and two well-functioning NGO health programmes targeted to farmworkers. This study examines the farm employers role in mediating the delivery of health and HIV services to farmworkers.
**Methods:** A mixed methods study (secondary quantitative and primary qualitative data) purposively sampled 20 commercial farms serviced by government and NGO health services. The sample was stratified to include farms with less than 100, between 100 and 500, and more than 500 workers. In-depth, semi-structured interviews were conducted with the employer at each site to explore attitudes and practices to HIV and related health services for farmworkers. Complementary information was collected about health service provision and the policy environment.
**Results:** The Panado Problem is a metaphor for the status quo amongst farm employers to HIV, health and wellness of their workers. Panado, a paracetamol based painkiller, was referenced by farm employers to describe both the promise and failure of heath services, highlighting a complex set of contradictions faced by the employer. These contradictions are found: In the policy environment: Policy prohibits the dispensing of medicine at workplaces, whilst employers illicitly dispense Panado as an act of care. In health service delivery: Farm employers dependent on public health services for productive workers cite the commonly dispensed Panado as inadequate medication for the health problems of farmworkers, including HIV. In workplace determined expression of worker rights to HIV care and support: Access to health care is time and productivity for the employer, which when pitted against workers' right to privacy, places employers in an ambivalent position regarding access to HIV and health services for workers.
**Conclusions:** Two models of NGO service provision ease the mediation of these persistent contradictions, but do not resolve these for either the employer or worker.

## TUPED329

### TECHNOLOGY-RELATED PREDICTORS OF SOCIAL ISOLATION AMONG YOUNG BLACK MSM

L. Hightow-Weidman[1], S. LeGrand[2], K. Soni[1], H. Kirschke-Schwartz[1], S.K. Choi[3], K. Muessig[3]
*[1]Behavior and Technology Lab, Institute for Global Health and Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, United States, [2]Duke, Global Health Institute, Durham, United States, [3]University of North Carolina-Chapel Hill, School of Public Health, Health Behavior, Chapel Hill, United States*
*Presenting author email: sara.legrand@duke.edu*

**Background:** Young black men who have sex with men (YBMSM) are disproportionately affected by HIV. Social networking sites facilitate opportunities for YBMSM to meet sex partners, but may also create supportive communities and provide health information access.
**Methods:** healthMpowerment.org (HMP) is a mobile-phone-optimized, Internet-based intervention for YBMSM that provides information, resources, tailored feedback, and social networking platforms to offer and receive social support from peers. A randomized controlled trial of HMP enrolled 474 YBMSM in North Carolina between November 2013 and October 2015. Bivariate and multivariate analyses were conducted at baseline to identify technology-related predictors of social isolation measured by perceived social support received by family and friends using the Lubben Social Network Scale-6.
**Results:** The mean age was 24.3 years, 39.5% were HIV+. Men reported a mean of 7.35 hours of Internet use per day, 98.3% went online using a mobile device in the past month and 96.1% owned smartphones. Almost all (98.7%) had $\geq$1 account on a social networking site; the mean number of accounts was 3.62. Overall 36.4% of participants were socially isolated. Socially isolated YBMSM had fewer social networking accounts (3.16 versus 3.88; $p < 0.01$), and were less likely to use Twitter or Instagram compared to those who were not socially isolated. There was no differ-

ence in Facebook usage between the groups. Those who were socially isolated were less likely to search for sex partners online, though were more likely to search for partners using Craigslist (p< 0.01). Social isolation was associated with less health application (app) usage in the previous three months (30.8% vs. 40.5%, p=0.038). In multivariate analysis controlling for age, education, income and HIV status, a greater number of social network sites used (OR 0.87; CI 0.76-0.99) and health app usage (OR 0.64, CI 0.41-1.00) were associated with decreased social isolation.
**Conclusions:** Online social networks may help YBMSM find like others and reduce feelings of social isolation. This could be particularly important for those living in rural areas or who face stigma around their sexuality or HIV-status. A comprehensive understanding of YBMSM online behaviors, including usage patterns and specific sites used, can inform future prevention interventions.

## TUPED330

### YOUTH AND ALCOHOL: USING PHOTOVOICE PARTICIPATORY METHODS TO UNDERSTAND THE ROLE OF ALCOHOL AVAILABILITY, PROMOTION AND AFFORDABILITY ON YOUNG PEOPLE'S HIV RISK AND SAFETY IN SOUTH AFRICA

L. Letsela[1], R. Weiner[2], K. Fritz[3], STRIVE Alcohol Study Group
*[1]Soul City Institute, M&E, Johannesburg, South Africa, [2]Soul City Institute, Public Health Specialist, Johannesburg, South Africa, [3]International Center for Research on Women, Research, Washington, DC, United States*
*Presenting author email: lebohang@soulcity.org.za*

**Background:** South Africa has one of the highest rates of heavy episodic drinking in the world and a strong link between alcohol misuse and HIV sexual risk behaviour has been found. This study aimed to quantify the availability of alcohol and document the lived reality of youth as they see alcohol advertisements and promotions in their everyday lives.
**Methods:** The study was conducted in a rural village and an urban township in South Africa. GPS mapping of alcohol outlets captured the density, distribution and proximity of venues to community resources i.e. schools. Alcohol adverts/promotions were captured at each venue. PhotoVoice methodology was used to understand young adults' perceptions of alcohol availability, pricing and promotions in their communities, and how these influenced sexual risk and safety. GPS coordinate data were analysed using QuantumGIS. Focus group discussions were analyzed thematically using ATLAS ti.
**Results:** Alcohol was widely available with 4 -5, and 8-10 alcohol outlets per main street in the rural site and urban site, respectively. Youth have easy access to alcohol due to weak implementation of regulations at retail points, and at community gatherings. Adults sending children to purchase alcohol on their behalf was a common experience. Alcohol advertising was attractive and often led youth to try different brands and beverages. Promotional activities including celebrity events and discounts *`happy hour' or `buy 1 get 1 free'* attract youth to taverns. Youth are exposed to gendered marketing strategies that attract women to drink ciders/alcopops and men to drink beer. While respondents cited some benefits for alcohol consumption including employment, decreased emotional distress, bravery and heightened fun, they mostly discussed the negative consequences including interpersonal violence, loss of employment, unsafe sexual intercourse and potential sexual assault.
**Conclusions:** Alcohol is a structural driver of HIV risk and is commonly overlooked by the HIV prevention field. Easy access and strong alcohol advertising campaigns increase youth vulnerability to harmful drinking and related sexual risk behaviour. There is a need to regulate alcohol availability in communities, while advocacy, public education and media literacy are required to shift norms that advertisers use to attract youth to consume alcohol.

## TUPED331

### EXPERIENCES OF POLICE VIOLENCE AMONG BEHAVIORALLY BISEXUAL AFRICAN AMERICAN MEN AND THEIR FEMALE PARTNERS: THE STRUCTURAL CONTEXT OF HIV

S. Mackenzie[1], M. Benjamin[2], J. Kalamka Johnson[3], M. Khan[4], S. MacGregor[4], E. Hailu[4]
*[1]Santa Clara University, Public Health Program, Berkeley, United States, [2]Cal-Pep, Oakland, United States, [3]St. James Infirmary, San Francisco, United States, [4]Santa Clara University, Santa Clara, United States*
*Presenting author email: smackenzie@scu.edu*

**Background:** Police violence disproportionately targets African American men and women in the United States, and research increasingly demonstrates linkages between police violence and risk for HIV and STIs.
**Methods:** We developed the Experience of Police Violence Scale as a 26-question measure to assess direct and observed experiences of verbal, physical, and sexual violence by police officers, and to assess perceptions of law enforcement and the effects of these on HIV risk behaviors. Data are being collected in an ongoing mixed methods HIV prevention study with behaviorally bisexual African American men and their female partners in the San Francisco Bay Area.
**Results:** Analyses conducted with 46 interviews completed to date (30 male, 16 female) indicate high rates of lifetime, past year, and recent (six month) experiences of observed and direct police violence. Men reported higher rates than women of witnessing (73% of men, 56% women) and directly experiencing police harassment (57% of men, 44% women), and witnessing (47% of men, 38% of women) and experiencing police physical abuse in their lifetime (40% of men, 25% of women). Sexual abuse by police officers was less common. 57% of the men and 44% of women reported that they have chosen not to carry safer injection materials (syringes, cookers, etc.) for fear of being targeted by the police. The area in which women reported higher effects of police fear was in carrying condoms - almost one third (31%) of women reported choosing not to carry condoms for fear of being targeted by the police (compared with 21% of men). 100% of women agreed with both of the statements that "Police officers unfairly target Black Men" and "Police officers unfairly target Black women," while 83% and 80% of men agreed with those statements, respectively. Approximately two thirds of the sample reported that the police unfairly target LGBT people, and that they avoid asking the police for help when they need it.
**Conclusions:** These findings indicate the effects of police violence and fear of police violence on HIV risk among two populations disproportionately impacted by HIV, African Americans and sexual minorities. Further research is needed to examine these linkages longitudinally.

## TUPED332

### SAFE SPACE AND HIV: EXAMINING THE RELATIONSHIP BETWEEN THE PHYSICAL FEATURES OF SEX WORK VENUES, WOMEN'S SAFETY AND CONDOM USE NEGOTIATION IN TWO MEXICO/U.S. BORDER CITIES

B.S. West[1], E.E. Connors[1], C. Magis-Rodriguez[2], H. Staines-Orozco[3], G. Martinez[4], A. Roth[5], R. Fielding-Miller[1], K.C. Brouwer[1]
*[1]University of California, Division of Global Public Health, San Diego, United States, [2]Universidad Autónoma de Ciudad Juárez, Departamento de Ciencias Médicas, Cuidad Juárez, Mexico, [3]Secretaría de Salud, Centro Nacional para la Prevención y el Control del VIH/SIDA (CENSIDA), México City, Mexico, [4]Federación Mexicana de Asociaciones, Salud y Desarrollo Comunitario de Ciudad Juárez, Cuidad Juárez, Mexico, [5]Drexel University, Community Health and Prevention, Philadelphia, United States*

**Background:** The physical and geographical characteristics, as well as social meanings, related to 'place' are increasingly recognized as key factors driving individual and community health risks. This is especially true among marginalized populations, such as female sex workers (FSWs). Aside from research on types of venues where women work, little has been done to describe how the built environment and physical characteristics of these places contribute to HIV/STI among FSW. In this paper, we examine the association between FSW venue characteristics, perceived workplace safety, and women's ability to convince clients to use condoms in two Mexico/U.S. border cities.
**Methods:** This study includes 602 FSWs from Tijuana and Ciudad Juarez, Mexico, selected through time-location sampling within indoor and street venues. All participants completed a survey and biological testing for HIV/STI at baseline. Using logistic regression, we assessed whether perceived workplace safety and the ability to convince an unwilling client to use a condom varied by FSW venue characteristics (e.g. security, working conditions, law enforcement, presence of drugs/alcohol). Models controlled for education, income level, marital status, and city.
**Results:** Almost 76% of the sample were unmarried, 38% had completed at least secondary education, and the mean age was 34. FSW who witnessed a fight at their workplace (AOR (adjusted odds ratio)=0.55, p< 0.01) and those who worked near bars (AOR=0.64, p=0.05) felt less safe conducting sex work, while FSW working in venues with locked gates or security guards felt safer (AOR=1.745, p=0.05). Working in places that required FSW to use condoms (AOR=02.89, p=0.007), had alcohol for sale (AOR=2.03, p=0.01), and in areas with regular police patrols
(AOR=2.81, p< 0.01) was associated with greater condom use efficacy. FSW working close to bars had lower ability to convince clients to use condoms (AOR=0.49, p=0.05).
**Conclusions:** Examining how the physical features of FSW venues shape women's safety and risk behaviors is essential to understanding the structural drivers of HIV/STI. Future research should leverage information on venues in order to develop new approaches for HIV prevention and intervention in resource constrained areas.

## TUPED333

### SEX, HIV AND BUREAUCRACY: ACTIVISM IN THE ERA OF "-IZATIONS"

L. Murray
*Institute of Social Medicine / State University of Rio de Janeiro, Department of Health Policy, Planning and Administration, Rio de Janeiro, Brazil*
*Presenting author email: laurinhamurray@gmail.com*

**Background:** Studies have increasingly confirmed the fundamental role of structural and social drivers of HIV. Yet many analyses of the impact of social and political factors on the bureaucratic processes through which the epidemic is "administered" by activist organizations remain superficial. In Brazil, broad changes over the past decade in how HIV funding is dispersed have been aggravated by recent political setbacks in the arena of sexual rights, creating challenges for many NGOs. This research explored the relationship between sex worker rights organizations and state AIDS bureaucracies to understand how contextual factors influenced various bureaucratic "-ization" processes (ex. institutionalization, decentralization) during this time period.
**Methods:** Ethnographic fieldwork was conducted from November 2011 through October 2014 in three Brazilian cities. The research presented draws on participant observation with sex worker rights organizations, 21 oral histories with sex worker activists and 22 in-depth interviews with AIDS activists and AIDS program administrators at the state and municipal levels.
**Results:** Bureaucracy emerged in narratives as both a hurdle to activism and a scapegoat for State responsibility. Activists identified institutionalization as one of their main impediments to realizing their grassroots advocacy work. Organizations were overwhelmed by bureaucratic requirements for reporting and funding requests, emphasizing how consequences for not following the rules appeared to increase at the same rate that the political climate became more conservative. State officials also shared deep frustrations with the restrictions surrounding government funding for NGOs. A history of blurred and contested lines between government and non-governmental responsibilities added an important layer of complexity to the analysis. Sex worker organizations responded using cultural interventions to circumvent deleterious effects of bureaucracy.
**Conclusions:** Although generally portrayed as neutral, bureaucratic "-ization" processes are often contrary to activist goals, transforming power into something that comes from following the rules as opposed to questioning them. Many of the difficulties sex worker activists faced are related to a broader pattern of how the Brazilian State has historically structured its relationship to prostitution to align with current sexuality politics and neoliberal agendas. Understanding the social and political aspects of AIDS bureaucracy opens up avenues for creative intervention strategies to ameliorate its negative effects.

## TUPED334

### *"MOVING FROM VISIBLE TO VIRTUAL SPACES"* VISIBILITY, NETWORKING AND MOBILITY AMONG MEN WHO HAVE SEX WITH MEN FROM GOA STATE: DRAWINGS FROM A PRE-SURVEILLANCE ASSESSMENT

S. Deshpande[1], P. Kumar[2], N. Joglekar[1], C. Kadu[1], N. Dhingra[2], R. Gangakhedkar[1], S. Godbole[1]
*[1]National AIDS Research Institute, Pune, India, [2]Department of AIDS Control, New Delhi, India*
*Presenting author email: sucheta.ibba@gmail.com*

**Background:** A Pre-surveillance assessment (PSA) was done to understand community concerns and develop strategies for conducting a large scale community based bio-behavioural surveillance in India. We analyzed data from this qualitative assessment conducted in the small state of Goa, Western India, a popular tourist destination.
**Methods:** PSA was conducted among MSM in both districts of Goa (South and North) during July-September 2013. Five group discussions (GD), (South Goa=2, North Goa=3) and 13 in-depth interviews (IDI) (South Goa=7, North Goa=6) were conducted with key stakeholders and community members. All the GDs and IDIs were taped after seeking consent. Emerging strands from the data, specifically on visibility, networking and mobility among MSM are presented here.
**Results:** Almost all respondents highlighted the reduced visibility of MSM in Goa. While effeminate appearance was quoted as maximally impacting MSM visibility, respondents suggested that their partners however, tended to blend into the society especially in the urban areas. Rural residence, socio-familial pressure and homophobia were reported as major factors for reduced visibility among MSM. A gradual but definite change in congregation and networking points from the public (hotspots) to non-conventional virtual spaces was reported. During summer and rainy seasons, intrastate mobility of MSM was observed while carnival, festive and tourist seasons saw influx of MSM from other Indian states.
**Conclusions:** Conventional interventions usually target the more visible, hotspot based MSM. However, in the current era, movement of MSM from conventional to virtual spaces is a challenge for HIV prevention interventions as well as community based surveys. There is an urgent need to identify and develop approaches for outreach to MSM with higher mobility and less visibility. Non-conventional interventions leveraging web-based and mhealth options for MSM should be a focus in India.

## TUPED335

### CONTEXTS OF VULNERABILITY TO HIV AMONG ELDERLY MEN WHO HAVE SEX WITH MEN IN ASUNCION, PARAGUAY: AN EXPLORATORY STUDY

M. Negrete
*NGO Fundación Vencer, Asunción, Paraguay*
*Presenting author email: negretema@gmail.com*

**Background:** The aim of the present study was to gain an in-depth understanding of the contexts of vulnerability to HIV infection at political, economic, social and individual levels among men aged 64 years or over who have sex with men (MSM) in Asunción, Paraguay.
**Methods:** we carried out an exploratory and descriptive qualitative study using a phenomenological approach. Semistructured interviews were administered to a theoretical sample of 16 MSM aged 64 years or over in Asunción, Paraguay, and we conducted thematic content analysis of the narrative text.
**Results:** Among the main results, we were able to identify various beliefs, attitudes and behaviors which could give rise to HIV vulnerability emerging from their individual, social and political contexts, but not their economic contexts. In the political context, we found a failure to identify with the gay community, or to participate in civil associations. At social level there was a notable perception of discrimination due to sexual orientation and age, and a weakening of their social networks. At the individual level, sexuality continues to be an important part of participants' lives, and while the frequency of relations declines, they obtain sexual gratification in saunas or through paying for sex. The fear of loneliness in old age and physical deterioration, added to a certain degree of internalized homophobia, has a considerable impact on their affective lives.
**Conclusions:** The majority did not identify with HIV prevention campaigns targeting the gay population and other MSM, and hence they do not perceive HIV as a potential threat. In conclusion, we may assume that the perceived risk is attributed to individual decisions and not to underlying social or political factors. The lack of empowerment and invisibility resulting from discrimination increases their [EV1] vulnerability to HIV. Finally, this study provides recommendations useful for health promotion and empowerment among elderly MSM.

## TUPED336

### THE CASE FOR CONSIDERING SOCIAL VENUE-BASED INTERVENTIONS AND RISKY GROUPS INTEGRATED HIV PREVENTION EFFORTS

S. Babirye[1], S. Ssendagire[1], M. Nattimba[2], S. Kasasa[3], L. Atuyambe[4], S. Weir[5], F. Ssengooba[1]
*[1]Makerere University School of Public Health, Health Policy, Planning, and Management, Kampala, Uganda, [2]Makerere University College of Health Sciences, Kampala, Uganda, [3]Makerere University School of Public Health, Epidemiology and Biostatistics, Kampala, Uganda, [4]Makerere University School of Public Health, Community Health, Kampala, Uganda, [5]University of North Carolina, North Carolina, American Samoa*
*Presenting author email: babiryes2004@gmail.com*

**Background:** Targeted interventions have been highly documented for their effectiveness in controlling the spread of HIV among persons most vulnerable to HIV. However, these interventions have not been extended to social venues like bars, hotels, and night clubs e.t.c. Socializing venues are a hub for different risky groups because of their male centric nature of activities.The purpose of this study was to characterize socializing sites in Uganda with an aim to expand HIV prevention services.
**Methods:** The data used in this study are part of a larger population-based survey conducted in Uganda between 2013 and 2014 using the PLACE methodology http://www.cpc.unc.edu/measure/resources/publications/ms-05-13. In short, 1) social sites where people meet new sexual partners were mapped and characterized and 2) assessed for availability and coverage of HIV prevention services such as condoms and IEC. The study included; a survey of 7,587 community informants; 2642 key informant interviews with venue informants (i.e. a person knowledgeable about the venue).
**Results:** A total of 7688 unique social sites were identified by 7,587 community informants in 30 districts. The most common types of venues visited were bars and lodges. Alcohol consumption was common (77.7%) to the venues. New sexual part-

nerships were reported among 69.9% of the venues verified. Commercial sex workers, MSM, and workers at these sites were among the key populations identified at the sites. Most sites were quite stable, with over 70% being in operation more than one year. There were gaps in HIV prevention programs at these sites. For example, 14.2%, 13.1% and 9.8% of the verified sites had any free condom distribution, any condoms for sale, and any safe sex education observed respectively. Willingness of site managers to have HIV prevention programs was high at over 65%.
**Conclusions:** The study findings suggest that social sites are a viable place for reaching key populations and are characterized with sex-related activities yet have sub-optimal HIV prevention services. Therefore targeted HIV interventions should be focused on finding these sites and use them as platforms for providing services in order to address the unmet need for prevention services and be able to interrupt transmission where it is concentrated.

## TUPED337

### BARRIERS TO PRE-EXPOSURE PROPHYLAXIS (PREP) ENGAGEMENT FOR BLACK MEN WHO HAVE SEX WITH MEN IN NEW YORK CITY: WHY PREVENTION LITERACY MATTERS

M.M. Philbin[1], R.G. Parker[2], C. Parker[3], J. Garcia[4], P.A. Wilson[2], J.S. Hirsch[2]
*[1]Columbia University, New York State Psychiatric Institute, HIV Center for Clinical and Behavioral Studies, New York, United States, [2]Columbia University, New York, United States, [3]Columbia University Mailman School of Public Health, New York, United States, [4]Oregon State University, Corvallis, United States*
*Presenting author email: mp3243@columbia.edu*

**Background:** Black men who have sex with men (BMSM) have the highest HIV incidence rates in the US. New prevention methods such as pre-exposure prophylaxis (PrEP) provide strategies to address HIV-related vulnerabilities among BMSM, but there has been insufficient consideration of how community-level factors shape PrEP uptake. This ethnographic study assessed the approaches necessary to advance PrEP as a prevention strategy for BMSM in New York City (NYC).
**Methods:** BMSM in NYC (n=31) participated in three 90-minute in-depth interviews. We also interviewed seventeen community stakeholders. Interviews were taped, transcribed, and analyzed within and across cases to explore individuals' experiences with HIV prevention (specifically PrEP).
**Results:** Three key findings demonstrated the community-level challenges to PrEP adoption: (1) Men described feeling a lack of ownership over existing HIV prevention tools. Most reported HIV-related risk behaviors but were uncomfortable with, and even unaware of, prevention options aside from condoms. The few men who knew about PrEP felt that it was forced upon the community and expressed a desire for a wider range of prevention options. (2) Many BMSM expressed an intense distrust of the medical establishment and reported strong resistance to taking a pill simply because their doctor said they should, which could diminish the likelihood of BMSM adopting PrEP. (3) Participants felt disempowered by healthcare providers when they voiced their own healthcare-related needs and the prevention options that might best fit within them. BMSM' interactions with healthcare providers did not provide opportunities for them to take ownership over HIV prevention behaviors that would serve their unique needs.
**Conclusions:** For the promise of PrEP to be fulfilled for BMSM, it is vital to pair the provision of PrEP with community-based education approaches. Similar to how "treatment literacy" campaigns support treatment access, "prevention literacy" at the community level can be a critical strategy to facilitate genuine grassroots demand. Consciousness-raising and mobilization efforts are essential for BMSM to
(1) choose PrEP based on their prevention needs and not at the behest of a provider;
(2) understand how the medication works to facilitate adherence;
(3) comprehend medical results and outcomes, and
(4) feel comfortable discussing their sexual practices with providers.

## TUPED338

### RESEARCH ON SOCIAL CAPITAL AND HIV OUTCOMES IN THE UNITED STATES: RESULTS, CHALLENGES AND FUTURE DIRECTIONS

Y. Ransome[1], L. Dean[2]
*[1]Harvard T.H. Chan School of Public Health, Social and Behavioral Sciences, Boston, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States*
*Presenting author email: yransome@hsph.harvard.edu*

**Background:** Social capital is broadly defined as the structure of networks and collective resources within a community that residents can benefit from. Social capital is a key determinant of HIV outcomes (e.g., HIV incidence and late HIV diagnosis) in the population. Research on social capital and HIV is limited in the United States setting. We therefore investigated the ecological links between social capital and HIV outcomes along the stages of HIV care. We discuss the state of the evidence globally and within the United States, present our empirical findings and close by highlighting challenges and future directions of the research.
**Methods:** We examined whether neighborhood social capital (social cohesion, social participation, and collective efficacy) in 2004-2006 is associated with lower 5-year average (2007-2011) prevalence of late HIV diagnosis and higher prevalence of persons linked to HIV and engaged in HIV care within Philadelphia, PA Census tracts (n=332). In a second study, we conduct ecological analyses (ZIP code, N=166) using negative binomial regression of gender-specific rates of late HIV diagnoses (an AIDS defining illness or a CD4 count ≤200 cell/μL within 12 months of a new HIV diagnosis) in 2005 and 2006 obtained from the New York City HIV Surveillance Registry, and social capital indicators (civic engagement, political participation, social cohesion, and informal social control) from the New York Social Indicators Survey, 2004.
**Results:** Higher social and political participation was associated with lower rates of late HIV diagnosis in New York City (NYC), but higher rates in Philadelphia. Social cohesion was associated with lower rates of late HIV among women in NYC but unrelated to the outcome in Philadelphia. Collective efficacy was associated with lower rates of late HIV diagnosis but conversely lower prevalence of engagement in HIV care in Philadelphia.
**Conclusions:** The associations between social capital and HIV outcomes vary across social capital indicators, gender, geographic level, and urban setting. Limitations include inability to determine causal inference, lack of subgroup stratified social capital or HIV data by transmission risk. Study strengths are population HIV surveillance and social capital data. Findings underscore the need for longitudinal and multilevel research on the topic.

# SOCIO-ECONOMIC DIFFERENCES: POVERTY, WEALTH AND INCOME INEQUALITIES

## TUPED339

### ASSESSING HOUSEHOLD ECONOMIC VULNERABILITY IN HIV-AFFECTED COMMUNITIES IN FIVE REGIONS OF CÔTE D'IVOIRE

H.M. Burke[1], W. Moret[2], S. Field[3], M. Chen[3], Y. Zeng[3], F.M. Seka[4], M. Ferguson[5]
*[1]FHI 360, Reproductive, Maternal, Newborn, and Child Health, Durham, United States, [2]FHI 360, Social and Economic Development, Washington, D.C., United States, [3]FHI 360, Biostatistics, Durham, United States, [4]Synergie Expertise, Abidjan, Cote D'Ivoire, [5]FHI 360, Pretoria, South Africa*
*Presenting author email: mferguson@fhi360.org*

**Background:** Economic strengthening interventions are used in programming for vulnerable children to curb the effects of poverty on susceptibility to HIV and to mitigate the economic effects of HIV. Our objective was to identify and describe levels of household economic vulnerability in HIV-affected communities in Côte d'Ivoire to inform and target economic strengthening interventions for vulnerable households. Our approach was to identify sets of correlated vulnerabilities and derive a small number of composite scores to create an index or scorecard that could be used to target vulnerable populations with a standard package of interventions to reduce their vulnerability.
**Methods:** In March and April 2015, we conducted a cross-sectional survey of 3,749 households in 78 purposively selected villages or urban neighborhoods in five health regions of Côte d'Ivoire. In each region, households with current and potential beneficiaries of services provided by the United States Agency for International Development and the President's Emergency Plan for AIDS Relief (USAID/PEPFAR) were randomly selected using a stratified multistage sampling design. Sixty-five distinct measures of vulnerability were submitted to a principal component analysis (PCA). Using correlations, indices measuring other domains of vulnerability were compared to the components resulting from the PCA.
**Results:** Four components were retained and explained only 21% of the total variance in the measures. The component with the largest number of associated measures indicated a household's level of wealth and food security. Findings from the PCA, as well as the other indices, suggest that USAID/PEPFAR serves the most vulnerable households in the study regions on several, but not all, measured dimensions of vulnerability.
**Conclusions:** The vulnerability measures did not cluster in ways that would allow for the creation of a small number of composite measures. Instead, we found numerous pathways to vulnerability such that households have their own unique set of conditions making them vulnerable. Our findings suggest that simple indices are inadequate to capture a broad concept of HIV-related economic vulnerability, and that donors and implementers should avoid simplified quantitative targeting tools in this context. Instead, a case management approach may be the best way to address the complex pathways of vulnerability.

## TUPED340

### DATA MINING REVEALS DISPARITIES IN HIV VIRAL LOAD SUPPRESSION

D. Feller, B. Agins
*New York State Department of Health, AIDS Institute, New York, United States*
*Presenting author email: danieljfeller@gmail.com*

**Background:** Viral load suppression (VLS) through effective antiretroviral therapy (ART) reduces the risk of morbidity and mortality for people living with HIV (PLWH) and reduces the likelihood of transmission. Health disparities are well documented among PLWH and can be manifested by age, race or ethnicity, sexual orientation and income. Contemporary analytical techniques may provide a more precise modeling of disparities than traditional statistical techniques and identify common barriers to VLS.
**Methods:** We evaluated viral load suppression among a sample of 11,419 adult PLWH receiving treatment from 186 New York State HIV clinics in 2013. Information from patient medical records was abstracted using manual chart review. Disparities in VLS were examined with classification and regression tree analysis (C&RT), a commonly used data mining technique.
**Results:** 77.8% (8,885) of patients were virally suppressed. C&RT identified 8 mutually exclusive subgroups with varying rates of VLS. Housing status, substance abuse, and insurance payer and not race/ethnicity were predictive of viral load suppression. Patients who abused substances and were unstably housed had the lowest rate of VLS (56.2%).
**Conclusions:** Substantial disparities in viral load suppression rates exist among patients engaged in HIV medical care. Racial and ethnic inequalities likely reflect social determinants of health including housing instability and substance use. The information-rich results from C&RT can be used as a basis for targeted and tailored interventions to improve patient and population health outcomes.

## TUPED341

### SOCIAL AND ECONOMIC BARRIERS TO CARE AND TREATMENT FOR BLACK MEN WHO HAVE SEX WITH MEN AND WOMEN (BMSMW) WHO ARE LIVING WITH HIV: LESSONS FROM THE BRUTHAS COHORT

E. Arnold[1], J. Weeks[1], M. Benjamin[2], L. Pollack[1], G. Lockett[2], D. Operario[3], S. Kegeles[1]
*[1]University of California, San Francisco, United States, [2]California Prostitutes Education Project (CAL-PEP), Oakland, United States, [3]Brown University, Providence, United States*
*Presenting author email: emily.arnold@ucsf.edu*

**Background:** Black MSM suffer astonishing rates of HIV, with 20-25% of incident cases in the US. A subset of BMSM, BMSMW, are diagnosed later, and are more likely to be poor and have reduced access to health care than BMSM. BMSMW often insist on secrecy about their same sex desire as well as their HIV status, and may experience unique barriers to seeking regular care and treatment, and achieving viral suppression.
**Methods:** From February 2011-May 2014, we recruited 400 BMSMW in the San Francisco Bay Area into a randomized controlled trial, of whom 13% (52) men reported being HIV+. To learn more about their care and treatment experiences, we invited N=25 to be interviewed between May-December 2014. Topics included: current living situation, social support and disclosure, experiences of accessing and maintaining care and treatment, and HIV-related stigma. Recordings were transcribed and coded for major themes, which were discussed in analytic memos.
**Results:** Men faced significant social and economic barriers to maintaining regular care and treatment adherence. At baseline, 40% were homeless in the past year and 80% were currently unemployed. Participants had trouble securing affordable housing, found disability payments inadequate to cover subsistence needs, and felt frustration over their inability to gain formal employment and stable income. Concerns over meeting basic needs took precedence over medical appointments and medication adherence. Pursuing opportunities in the informal economy was reported as a reason for missing medical appointments, and losing pills on the streets and the lack of privacy in homeless shelters made it difficult for unstably housed men to remain adherent to treatment. Men received little social support from family or friends for being in care or on treatment because of their reluctance to disclose their HIV status to others given their concerns about homophobia and HIV-related stigma.
**Conclusions:** HIV health promotion efforts for BMSMW must also include attending to their basic social and economic support needs. Integrating access to HIV care and treatment into services for poor unstably housed individuals may facilitate better adherence. Peer groups of BMSMW who are comfortable disclosing to each other could provide HIV-specific forms of social support to improve outcomes.

## TUPED342

### FOOD INSECURITY, HIV RISK BEHAVIOR AND VIOLENCE AMONG FEMALE SEX WORKERS IN INDIA: EVIDENCE FROM AVAHAN-III EVALUATION STUDY

S.K. Patel, M. Battala, R. Adhikary
*Population Council, HIV and AIDS Program, New Delhi, India*
*Presenting author email: sangrampatel@gmail.com*

**Background:** Food insecurity is one of the important contributing factors among female sex workers to engage in risky sexual behaviors and cause of HIV in developing countries. Studies exploring linkages between food insecurity and HIV risk behaviors among FSWs are limited despite having potential program and policy implications. This study attempts to assess the food insecurity among FSWs and examine its relationship with HIV risk behavior and violence in India.
**Methods:** Data were drawn from the Avahan-III baseline evaluation survey- 2015, conducted among FSWs (n=4098) using two stage cluster sampling approach in five states of India. Multivariate logistic regression (with adjusted odds ratios (AOR) and their 95% confidence intervals (CI)), bivariate analysis and frequency were used to assess the relationships between food insecurity, HIV risk behaviors and violence.
**Results:** Nearly one-fifth of FSWs (17%) reported of facing food insecurity in past 6 months. More than 35% of FSWs had entertained more clients to cope with the situation of food insecurity followed by defaulted on loans (24%), borrowed money from informal sources (20%) and had sex without condoms (7%). The likelihood of using consistent condom use with non-regular (67% vs. 77%; AOR: 0.6; 95% CI: 0.4-0.9) and regular partner (22% vs. 51%; AOR: 0.3; 95% CI: 0.2-0.4) were significantly lower among FSWs those had food insecurity than others. The likelihood of using consistent condom use with occasional (AOR: 0.5; 95% CI: 0.4-0.7) and regular clients (AOR: 0.8; 95% CI: 0.6-0.9) were significantly lower among FSWs those have reported food insecurity compared to those not. FSWs those faced food insecurity were also at higher degree of reporting STI symptoms (28% vs. 13%; AOR: 2.7) and violence (16% vs. 9%; AOR: 2.1) than their counterparts.
**Conclusions:** The findings of the study highlight that FSW's food insecurity is significantly associated with unprotected sex, other HIV risk behaviors and violence. This study underscores the need for community-led interventions focusing on food insecurity and economic strengthening activities to reduce HIV vulnerability among FSWs. However, further evidence based research and advocacies on food insecurity are required to ensure that HIV prevention programs are appropriately addressed.

## TUPED343

### LONG-TERM LABOUR MARKET ATTACHMENT PREDICTS KEY ANTIRETROVIRAL THERAPY OUTCOMES AMONG PEOPLE WHO USE ILLICIT DRUGS IN A SETTING OF UNIVERSAL HIV HEALTH CARE COVERAGE

L. Richardson[1,2], T. Kerr[1,3], J. Montaner[1,3], E. Wood[1,3], M.-J. Milloy[1,3]
*[1]B.C. Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, Department of Sociology, Vancouver, Canada, [3]University of British Columbia, Faculty of Medicine, Division of AIDS, Vancouver, Canada*
*Presenting author email: lrichardson@cfenet.ubc.ca*

**Background:** A growing body of observational research links employment with key measures of health among people living with HIV (PLHIV), including antiretroviral therapy (ART) adherence, mortality, and virologic suppression. However, studies to date have focused on employment at a single point in time rather than looking at labour market attachment over time.
**Methods:** Using data from the AIDS Care Cohort to Evaluate Access to Survival Services (ACCESS), a cohort of HIV seropositive people who use illicit drugs in Vancouver, Canada, we categorized labour market attachment as the proportion of all observations individuals report being in regular, temporary or self-employment, ranging from no employment (no observations), rarely employed (0-1/3), sometimes employed (1/3-2/3), and often employed (>2/3). Using multivariate generalized estimating equations, we then predicted associations between labour market attachment and ART outcomes in the previous six months, controlling for relevant confounders. Outcomes examined included no ART exposure to date, ART exposure with no dispensation, ART exposure with sub-optimal dispensation and optimal (>95%) ART dispensation.
**Results:** Between May 1996 and May 2015, of 1,136 participants, 608 (53.5%) reported no employment, 316 (27.8%) were rarely employed, 138 (12.1%) were sometimes employed and 74 (6.5%) were often employed. In GEE analyses, individuals in the rarely (adjusted odds ratio [AOR]: 0.64; 95% confidence interval [CI]: 0.50-0.84) sometimes (AOR: 0.62; 95% CI: 0.43-0.90) and often (AOR: 0.47; 95% CI: 0.27-0.80) employed groups were significantly less likely to be ART naïve than those reporting no employment. Additionally, individuals in the rarely (AOR: 1.33; 95% CI: 1.09-1.63) and sometimes (AOR: 1.47; 95% CI: 1.12-1.95) employed groups were significantly more likely to have some ART dispensation in the past six months, and

those who were often employed were significantly more likely than those reporting no employment to have optimal ART dispensation in the past six months (AOR: 1.50; 95% CI: 1.07-2.11).
**Conclusions:** This study documents low levels of labour market attachment among PLHIV who use illicit drugs and identifies labour market attachment over time as a significant differentiator for ART outcomes. Results point to the need for long-term strategies to promote labour market involvement among key affected populations.

## TUPED344

### FOOD INSECURITY IS ASSOCIATED WITH INTERNALIZED STIGMA AMONG WOMEN WITH HIV IN THE UNITED STATES

K. Palar[1], E.A. Frongillo[2], J. Escobar[2], L. Sheira[3], P. Tien[3], T. Wilson[4], A.A. Adedimeji[5], D. Merenstein[6], M. Cohen[7], E. Waddell[8], J. Turan[9], S.D. Weiser[1], Women's Interagency HIV Study
*[1]University of California, San Francisco, Department of Medicine, Division HIV, ID and Global Medicine, San Francisco, United States, [2]University of South Carolina, Columbia, United States, [3]University of California, San Francisco, San Francisco, United States, [4]State University of New York, Downstate Medical Center, New York City, United States, [5]Albert Einstein College of Medicine, New York City, United States, [6]Georgetown University, Washington DC, United States, [7]John H. Stroger Jr. (Cook County) Hospital, Chicago, United States, [8]Johns Hopkins University, Baltimore, United States, [9]University of Alabama Birmingham, Birmingham, United States*
*Presenting author email: sheri.weiser@ucsf.edu*

**Background:** Food insecurity and internalized HIV stigma are independently associated with poor HIV clinical outcomes, but few studies have examined how food insecurity and HIV stigma are related or mechanisms underlying these relationships. We hypothesized that food insecurity would be associated with internalized stigma, and that the association would be mediated via depression and poor physical health.
**Methods:** We used cross-sectional data collected in 2013 from the Women's Interagency HIV Study, a national multisite study of women with or at risk for HIV in the United States. Using validated scales, we assessed associations between food insecurity (Household Food Security Survey Module) and internalized stigma (HIV Stigma Scale). We assessed depressive symptoms (Center for Epidemiologic Studies Depression) and physical health status (SF-36) as potential mediators. We utilized recursive structural equation modeling to test study hypotheses, controlling for potential demographic, socioeconomic, and clinical confounders. The analysis included 1240 women with HIV.
**Results:** Almost half (41.6%) were food insecure (i.e. with marginal, low, or very low food security), and mean [SD] internalized stigma scores were 1.76 [0.63] (range 1-4, higher scores = higher stigma). In adjusted models, increasing severity of food insecurity was significantly associated with internalized HIV stigma, indicating a dose response relationship: $\beta$=0.09, $\beta$=0.21, and $\beta$=0.49 (all $p< 0.05$) for marginal, low or very low food security, respectively, compared to high food security. Increasing food insecurity was also associated with higher depressive symptom severity and worse physical health status (both $p< 0.05$). In mediation models of food insecurity and internalized stigma, only depressive symptom severity was significantly associated with stigma ($\beta$=0.02, $p< 0.05$) and attenuated the association with food insecurity. Mediation varied by marginal, low, and very low food security: 81.3%, 50.0%, and 35.2%, respectively, of the total association between food insecurity and internalized stigma operated via depressive symptoms.
**Conclusions:** Food insecurity is associated with internalized HIV stigma among women in the US, which may partially operate via depressive symptoms for women with less severe food insecurity. Our findings suggest that addressing food insecurity may be relevant to HIV stigma-reduction interventions. However, longitudinal studies are needed to confirm the direction of this important, preliminary association.

## DYNAMICS OF SOCIAL STATUS AND POWER: GENDER, AGE, ETHNICITY AND DISABILITY

## TUPED345

### "THESE MEN OF OURS HAVE SUCH FRAGILE HEARTS": ANTHROPOLOGICAL PERSPECTIVES ON GENDER DIFFERENCES IN TREATMENT OUTCOMES IN A LARGE-SCALE, PUBLIC-SECTOR HAART ROLLOUT PROGRAM IN NAMIBIA

M. Callaghan
*University of Toronto, Dalla Lana School of Public Health, Toronto, Canada*
*Presenting author email: mike.callaghan@mail.utoronto.ca*

**Background:** Namibia has achieved universal access to HAART. While equity has been a major focus of rollout, men continue to be treated in lower numbers and have worse outcomes than women. This study examines the socio-cultural factors behind gender disparities in HAART outcomes.
**Methods:** This in-depth study was conducted near Walvis Bay, Namibia. The mixed-methods approach combined a quantitative analysis of patient inputs and outcomes at a HAART clinic with 18 months of ethnographic research on 12 patients and ongoing participant-observation in the community.
**Results:** Men outnumber women in the city population (63%), but are under-represented in testing (51%), care (44%) and HAART initiation (47%), and over-represented in mortality (59.7%). This may be largely attributable to differences in gender roles. Establishing both 'modern, urban' and 'traditional/rural' feminine identity was complimentary to HAART. Many women reported testing positive in antenatal screening, which allows timely linkage to care. Motherhood was described as a guarantor of social capital and support, and a motivation for adherence. Among men, testing was not socially valued and the clinical and social requirements of HAART conflicted with gender roles that demand risk taking, employment (or the appearance of employment) and independence and discourage health-seeking behaviour. Many men felt frustrated by an inability to achieve and maintain masculine identity in a precarious economy, and described the demands of HAART as incompatible with masculinity. Those men who succeeded reported strong social support, disinterest in prevailing gender norms, and clinic cooperation with accommodating travel and work schedules.
**Conclusions:** Social-cultural and political-economic forces shape HAART outcomes powerfully. Efforts to better engage men will be crucial for ensuring equitable access to the benefits of HAART as rollout expands across sub-Saharan Africa. Men need safe pathways into care to facilitate earlier diagnosis, delivery methods that accommodate work and travel schedules, and support structures to improve retention.

## TUPED346

### MALE INVOLVEMENT AS A LINK TO PREVENTION OF MOTHER TO CHILD TRANSMISSION (PMTCT) OF HIV IN ABIA STATE NIGERIA

K. Igbojionu, E. Igbojionu, E. Okey-Uchendu
*Zinnok Initiative for Women and Children, Umuahia, Nigeria*
*Presenting author email: zinnokinitiative@yahoo.com*

**Background:** Male involvement explores community norms and values and also helps Health Systems to reach those who need the services. It assesses and makes use of existing community resources including sources of social influence in supporting PMTCT activities. Adherence depends a lot on spousal support therefore male involvement has greatly promoted Zinnok's activities in the communities by encouraging women to attend ANC with their partners at the first sign of pregnancy and also in making important decisions that will ensure that babies are born without any HIV infection.
**Description:** A huge number of Women in the state usually bear the burden of pregnancy and child birth alone but with male involvement messages, male support is noticed as men's interest to become more aware and to take positive action is evident. Male involvement has been seen to provide guidance to men on acceptance of PMTCT services.
**Lessons learned:** Zinnok initiative for women and children have trained about 600 men in Ukwa East and Ukwa West LGAs of Abia state, Nigeria on male involvement in PMTCT. These include the male partners of women of reproductive age and pregnant women. The men now encourage their wives to attend ANC, are involved in feeding options for their infants and encourage their wives to still go to primary health centers in the community for subsequent treatment and care even when they may have delivered at Traditional Birth Attendants (TBA) centers. There are discussions on infant feeding options with men and the men encourage testing of other family members. Engaging the males have been seen to decrease stigma and discrimination, increase accessibility to services and promotes acceptability of services. Awareness campaign and keying into men associations and meetings to share

information on male involvement are the methods used. The men in turn have one on one discussions with others to spread the information.
**Conclusions/Next steps:** Improving and strengthening male involvement in PMTCT services requires a male friendly approach. Increased interventions involving the men will help achieve much success in HIV prevention, Treatment and care.

## TUPED347

### UNDERSTANDING THE SOCIAL BARRIERS TO HIV SERVICE UTILISATION AMONG OLDER PEOPLE IN BOTSWANA

K. Matlho[1], R. Lebelonyane[2], T. Driscoll[1], J. Negin[1]
*[1]University of Sydney, Public Health, Sydney, Australia, [2]Ministry of Health Botswana, HIV Prevention and Care, Gaborone, Botswana*
*Presenting author email: kabo.matlho@sydney.edu.au*

**Background:** The impact of the HIV epidemic on older people is shaped by the social, political, demographic and economic circumstances in which they live. Projections point to a rise in the number of people aged 50 and older living with HIV (PLWH), in Botswana, as well as increased rates of new HIV infections within this sub population. Despite this, little is known about the social factors that affect HIV service utilization in this cohort.
**Methods:** We conducted semi-structured face-to-face, in-depth qualitative interviews with 50 consenting PLWH .>=50years. Interview questions examined the values, behaviours and social context of older adults to gain insight and explore the complexity inherent in living with HIV in Botswana. A conceptual framework for social analysis of reproductive health, developed by Price and Hawkins, was adapted to serve as a guide for our analysis.
**Results:** Negative stereotypes about older persons are a major challenge to healthcare utilisation among older people. Interviewees noted perceived isolation, rejection, stigma and ageism as their biggest challenge in their day-to-day interaction with the community and health personals in general. Current services focused on individual-level interventions and outcomes, thus neglecting structural interventions, community interventions and social outcomes. Interviewees felt that healthcare providers regarded support for older people as being primarily a family responsibility and hence feel obliged to be content with whatever services are rendered. They, however note rejection as the major the limitation for relying on family and friends for social support. Interviewees noted that less attention was paid to the complexities presented by sexual health and exploration, needs and demands among older adults, particularly older women, who are often rendered non-sexual and therefore not expected be sexually active. The majority of the interviews showed a lack of understanding in accessing and utilising public health services available and often felt at the mercy of the system riddled with "come back tomorrow" delayed report syndrome.
**Conclusions:** The quality of life in adults aging with HIV in Botswana is in question due to social isolation as well as medical complications, poorer mental health, institutionalised stigma and ageist tendencies from health care providers and society at large.

## TUPED348

### A STUDY OF FACTORS AFFECTING MALE INVOLVEMENT IN HIV-RELATED SERVICES IN MALAWI

B. Matatiyo[1], D. Likongwe[2]
*[1]National AIDS Commission, Planning Monitoring Evaluation and Research, Lilongwe, Malawi, [2]National AIDS Commission, Behaviour Change Interventions Unit, Lilongwe, Malawi*
*Presenting author email: dlikongwe@gmail.co*

**Background:** The HIV epidemic in Malawi is feminized, with an estimated 12.9% of women infected, compared to 8.1 % of men (aged 15-49). Evidence shows these services can be more effective and long lasting with active participation of their male counterparts. Involvement of males in HIV related services is important. Available evidence suggests the proportion of males actively involved in HIV services is lower than that of females. The main objective of the study was therefore to assess factors contributing to low male involvement in HIV related services.
**Methods:** A mixed method approach was used, including secondary analysis of data; review of relevant policy documents, study and program reports; key informant interviews at national, zonal and district levels and in-depth and focus group discussions. Non probability sampling methods were used in sampling participants.
**Results:** Respondents report that the health delivery system is male unfriendly, with health facilities located very long distances from most people and providing HIV services under environments deemed too public for a condition highly stigmatized. HIV services were observed to be concentrated in or near urban or semi urban areas. Societal construction negatively affects male health seeking behaviour, with men believing they must be invincible and seeking health attention is a sign of weakness. Fear of stigma and losing partners was another reported reason for minimal participation of males. Myths and misconceptions were also identified.
**Conclusions:** Despite concerted attempts to include male involvement as an approach to fight HIV infection; there is need to mainstream male involvement in programming and implementation. Male friendly environments as well as improved availability and access of male-targeted HIV services are needed. Integration of livelihood programs with HIV services and use of male peer campaigners may positively influence male participation. There is need to deconstruct gender based constructs that inhibit strong health-seeking behaviour among men.

## TUPED349

### BLACK AND *QUILOMBOLAS* HIGH SCHOOL STUDENTS VULNERABILITY TO HIV/AIDS: SEXUAL VIOLENCE, COMMUNITY STIGMATIZATION AND LACK OF ACCESS TO PREVENTION PROGRAMS SHOULD BE MITIGATED

V.N. Silva[1], M.C. Antunes[2], R. Casco[1], G. Tagliamento[2], E. Merchan-Hamann[3], V.S.F. Paiva[4]
*[1]University of São Paulo, Institute of Psychology, Dept. Social Psychology, São Paulo, Brazil, [2]Tuiuti University of Paraná, Master of Program on Psychology, Curitiba, Brazil, [3]University of Brasilia, Faculty of Health Sciences, Department of Public Health, Brazília, Brazil, [4]University of São Paulo, Institute of Psychology, Dept. Social Psychology, São Paulo, Brazil*
*Presenting author email: valerian@usp.br*

**Background:** Literature on Brazilian AIDS epidemic rarely analyzes race/ethnicity. Native Brazilians and black people are 51,1 % of the population and are socially vulnerable for all social indicators - schooling, jobs, housing, police violence and, of course, health. This study analyzed the singular vulnerability of *quilombolas* high schools students to HIV-infection in Brazil. *Quilombolas* are centuries-old black communities founded by Afro-descendants that escaped from slavery and stayed isolated until the 1960s, mostly in forests and sierras.
**Methods:** An ethnographic study and a survey among teenage students assessed HIV/pregnancy prevention knowledge, access to prevention tools and sexuality practices in 6 different school contexts in two Brazilian States, before a prevention-intervention. Three schools were in the Brazilian-DF capital metropolitan area and the other three were located at a SPaulo state rural area also serving *quilombola* communities. After parental authorization the students completed the survey. We analyzed data from all 925 students of 15-19 years old using reported "skin color", the Brazilian census category, categorized as non-black x black; subsequently, we compared *quilombola* students answers with their non-*quilombola* colleagues in the São Paulo region (n=372) using Kruskal Wallis and Pearson Chi-Square test (< 0.01).
**Results:** The only significant difference among black (62,5%) and non-black students in all 6 sites was an earlier age of first sexual intercourse. When comparing *quilombolas* (22% of 372) with non-*quilombolas* (78%) in São Paulo, this difference was larger (13,5 x 14,7). Still, *quilombolas* students had more sexual partners, lower prevention knowledge, lower AIDS risk perception, lower access to condoms; they were the segment more likely to report events of sexual abuse (20% x 5%). Ethnography showed different *quilombola* community experiences of stigmatization and a divided transition from traditional culture to recent adherence to Christian-evangelic churches. We could not discuss sexual violence within the consented research process.
**Conclusions:** The quilombola's social vulnerability as well as programmatic neglect is shared with other impoverish rural communities but have singularities demanding further research and investments to mitigate HIV/AIDS young people vulnerability, increasing in Brazil. Race-ethnicity and its related discrimination has been a cross-cutting issue to AIDS responses and should be focused in Brazil.

## Economic transitions and social and cultural change

### TUPED350

### Participation in economic strengthening (ES) intervention and health related quality of life (HRQoL) among food insecure people living with HIV (PLHIV) in Ethiopia

T. Bezabih, M.-S. Menbere
*World Food Programme, Urban HIV/AIDS Nutrition and Food Security Project, Addis Ababa, Ethiopia*
*Presenting author email: tsegazeab.bezabih@gmail.com*

**Background:** Health-related quality of life (HRQoL); a comprehensive indicator of physical, mental, and social well-being; is increasingly used to assess the well-being of people living with HIV (PLHIV). This study aims to explore the association between engagement in economic strengthening (ES) intervention and HRQoL among food insecure PLHIV.
**Methods:** Comparative cross-sectional design was employed to compare HRQoL scores of food insecure PLHIV benefitting from the ES project of WFP Ethiopia to food insecure PLHIV not participating in ES. The study covered 620 ES and equal number of non-ES PLHIV. The standard Medical Outcome Survey (MOS) was used to measure HRQoL. Multiple linear regressions were run to analyze the relationship between the dependent variable (QOL domain scores) and the independent variables.
**Results:** On the average, PLHIV that have stayed in ES activities for a year or more have consistently higher magnitude of HRQoL scores in all MOS sub-scales included in the study, namely; general health perceptions, pain, role function, social functioning, mental health, energy/fatigue, cognitive function, health distress and health transition compared to the comparison group that are either not engaged or just to start engaging in ES activities, all significant at 0.001 levels. The mean HRQoL score difference between the two groups ranges between 14.4 and 18.7, with the highest mean difference in health distress score and the lowest in self-esteem score. Controlling for key socio-economic and demographic variables, engagement in ES increases MOS sub-scales by 14 to 18 points, all significant at 0.001 levels. As suggested by the magnitude of the coefficients of multiple linear regression models, the impact of engagement in ES activities on HRQoL is much more pronounced in terms of health distress, role functioning, and general health scores.
**Conclusions:** Participation of food insecure PLHIV in ES is associated with improvement in HRQoL. This may mean that assisting PLHIV to extricate them out of poverty or to achieve food security through ES may be an important strategy to bring about improved health related quality of life which is important in the management of AIDS related illnesses.

## Economic and social dynamics and impacts of intergenerational and/or transactional sex

### TUPED351

### Increasing access to HIV services for young vulnerable female workers through their trade unions: the case of the hair and beauty trade union in Kenya

D. Muhika[1], H.M. Amakobe[2], R. Ameur[3], S. Mabhele[4]
*[1]Central Organization of Trade Unions in Kenya, Nairobi, Kenya, [2]International Labour Organization, ILOAIDS, Nairobi, Kenya, [3]international Labour Organization, Pretoria, South Africa, [4]Internaitonal Labour Organization, Pretoria, South Africa*
*Presenting author email: damarismuhika@gmail.com*

**Background:** HIV incidence in Kenya is currently at 101,000 new infections per year. Moreover, 53% of people living with HIV (PLHIV) do not know their HIV status. Prevalence is higher amongst women (7.6%) than men (5.6%), with 21% of new adult HIV infections among young women (15-24). This initiative mobilized trade unions in the hair and beauty sector to reach these vulnerable young women with information and services.
**Description:** The ILO partnered with the Central Organization of Trade Unions in Kenya, its affiliate, the Kenya Union of Hair and Beauty Salon Workers, and the AIDS Healthcare Foundation to increase HIV services for young women within the hair and beauty sector and expand their access to social protection. Due to the nature of their work - commission-based incomes, lack of job security and social protection - young women often resort to selling sex to supplement their low incomes, increasing their vulnerability to HIV.
Through this partnership, union branch officials were trained on HIV management at the workplace. Onsite integrated health/HIV testing and counseling (HTC) services were provided in workplaces, combined with sensitization on the benefits of enrolling with the National Hospital Insurance Fund (NHIF). The union mobilized workers to join the hair and beauty SACCO (Savings and Credit Cooperative), encouraging them to save a portion of their income. The results:
• 3,476 young women were tested for HIV and those testing positive were referred for treatment
• 1,725 young women registered with NHIF and 189 enrolled with the SACCO
• 12,100 male and female condoms were distributed.
**Lessons learned:**
• Integration of HIV/health services helps reduce stigma and increases uptake of HIV testing
• Engagement of trade union leaders, informal business association leaders and local administration is essential to effectively reach workers.
• Mobilization of vulnerable workers to register to NHIF and to enroll in saving schemes is key to ensure sustainable access to HIV services.
**Conclusions/Next steps:** Providing onsite HIV/health services enhances uptake; hence, the initiative will be replicated in additional hair and beauty worksites, as well as in female-dominated informal occupations, with the objective of reaching vulnerable young women with needed services.

## Violence and conflict: political, social, structural, interpersonal and family-based

### TUPED352

### Prevalence of intimate partner violence and physical and mental health outcomes of women living with HIV in an urban clinic setting

J. Anderson, N. Glass, J. Farley, J. Campbell
*Johns Hopkins University, School of Nursing, Baltimore, United States*
*Presenting author email: jocelyncanderson@gmail.com*

**Background:** Rates of intimate partner violence (IPV) in women living with HIV have been estimated at more than two times their HIV negative counterparts. IPV has been linked to a number of negative physical and mental health outcomes. However, limited data exists examining the impact of recent IPV on adherence to HIV care and subsequent treatment markers.
**Methods:** Women were recruited from an urban HIV specialty clinic. Women were eligible to participate if they had been attending the clinic for at least one year and reported having been in a relationship within the past one year. A one-time, tablet computer-based survey was used to assess past year IPV and reported mental health symptoms. These data were used in conjunction with medical records review to examine relationship between past year reports of IPV, mental health symptom and treatment markers (CD4 count and viral load measurements).
**Results:** A total of 242 women completed survey measures and had appropriate medical record data for inclusion. They were primarily black (92%) and non-Hispanic (99%). Half (n=122, 50%) reported some form of past year IPV. Of women reporting past year IPV, 39.3% reported depressive symptoms vs. 13.6% of women who had not experienced past year IPV ($p < 0.001$) a similar pattern was identified for PTSD symptoms (33.6% vs. 12.7%, $p < 0.001$). In a multivariable regression model controlling for age, ART use, PTSD, depression and substance abuse, women who reported past year IPV were twice as likely to have CD4 counts less than 200 (OR: 2.62, 95%CI: 1.005-6.81, p=0.049) and detectable viral load (OR: 2.14, 95%CI: 1.14-4.00, p=0.018).
**Conclusions:** Fifty percent of women in this study reported past year IPV. Women who experienced recent IPV were more likely to have CD4 counts below 200 and detectable viral load measurements. They also reported more symptoms of PTSD and depression. Biopsychosocial frameworks need to be used to assess adherence and response to HIV treatment. Assessment and intervention for ongoing violence as a potential cause of mental health issues, barrier to medication adherence and source of chronic stress may offer providers an opportunity to improve care to their patients living with HIV.

Tuesday 19 July Poster Exhibition

### ESTIMATING THE CAUSAL EFFECT OF INTIMATE PARTNER VIOLENCE ON CONDOM USE: AN APPLICATION OF MARGINAL STRUCTURAL MODELS TO COHORT DATA FROM RAKAI, UGANDA

L. Maxwell[1], H. Brahmbhatt[2], A. Ndyanabo[3], J. Wagman[4], G. Nakigozi[5], F. Nalugoda[3], D. Serwadda[6], A. Nandi[1]
*[1]McGill University, Epidemiology, Biostatistics and Occupational Health, Montreal, Canada, [2]Johns Hopkins Bloomberg School of Public Health, Population, Family and Reproductive Health, Baltimore, United States, [3]Rakai Health Sciences Program, Rakai, Uganda, [4]University of California at San Diego, Division of Global Public Health, San Diego, United States, [5]Rakai Health Sciences Program, Kalisizo, Uganda, [6]Makerere University, School of Public Health, Kampala, Uganda*
*Presenting author email: ftrudie@rhsp.org*

**Background:** Research indicates that women's experience of intimate partner violence (IPV) is associated with incident HIV and that women who experience IPV may be less likely to use condoms. Previous studies have controlled for covariates on the causal pathway between IPV and condom use, like pregnancy status, which may attenuate estimates of the effect of IPV on condom use. The goal of our study was to apply causal methods to a large cohort with repeated measures of IPV to estimate the effect of IPV on condom use.
**Methods:** We used data from waves 7-13 of the Rakai Community Cohort Study to estimate the effect of women's experience of IPV during the year prior to survey on condom use at last sex. Women aged 14-49 at baseline who reported ever having sex at baseline or during follow-up and answered IPV and contraception-related questions were included in these analyses (N=8,525). We used inverse probability weights to account for time-varying confounders that were affected by prior exposure to IPV. Stabilized weights were estimated using time-fixed confounders (religion, tribe, age at first pregnancy) and lagged values of time-varying confounders (age, relationship status, occupation, partner's occupation, education level, sexual and reproductive history, pregnancy intentions, pregnancy status, IPV exposure). A weighted marginal structural model, fitted with generalized estimating equations to account for the correlation of repeated measures within individuals, was used to estimate the effect of IPV on condom use.
**Results:** Women who experienced IPV in the year prior to survey were less likely to report condom use at last sex (Table 1) than women who did not experience IPV during that year. On average, any IPV, emotional, physical, or sexual IPV were associated with a 40% reduction in the odds of condom use at last sex.

| | Crude estimate | Unweighted logistic regression | Marginal structural model |
|---|---|---|---|
| Type of IPV | OR (95% CI) | OR (95% CI) | OR (95% CI) |
| Any IPV | 0.56 (0.51, 0.62) | 0.66 (0.59, 0.74) | 0.62 (0.56, 0.69) |
| Emotional IPV | 0.60 (0.54, 0.67) | 0.71 (0.63, 0.80) | 0.66 (0.59, 0.74) |
| Physical IPV | 0.51 (0.46, 0.58) | 0.60 (0.52, 0.68) | 0.56 (0.49, 0.64) |
| Sexual IPV | 0.56 (0.49, 0.63) | 0.64 (0.55, 0.74) | 0.58 (0.51, 0.66) |

*[Table 1. Estimates of the relation between women's experience of IPV in the last year and condom use at last sex (N=8,525; 2000-2010)]*

**Conclusions:** Women who experience IPV are less likely to use condoms. Understanding how IPV affects condom use has important implications for ensuring that HIV prevention programs can best serve women who experience IPV.

## TUPED354

### DETECTING, PREVENTING AND RESPONDING TO PHYSICAL, SEXUAL AND EMOTIONAL ABUSE AND NEGLECT THROUGH THE HIV CONTINUUM OF CARE

S. Chevrel[1], S. Long[2], K. Weinhauer[1], A. Beeler[1], A. Clark[3]
*[1]Catholic Relief Services, Baltimore, United States, [2]Maestral International, Oxford, United Kingdom, [3]Catholic Relief Services, 4Children, Baltimore, United States*
*Presenting author email: adele.clark@crs.org*

**Background:** Data from the Violence against Children (VAC) surveys and global analyses illustrate the scale and scope of violence against children and adolescents and emphasizes the urgency of responding effectively. 4Children, a USAID funded consortium, has undertaken a project to identify opportunities for violence prevention and response interventions within HIV paediatric testing, counselling and treatment services. The objective of this project is to develop guidance that will enhance detection, prevention and response to all forms of violence against children within HIV services.
**Description:** The project, initiated in July 2015, consists of:
- a literature review on the linkages between HIV and child protection;
- semi-structured interviews with over 25 key informants ranging from global policy-makers and in-country practitioners across nine countries;
- synthesis of findings to inform the development and validation of guidance tools.
**Lessons learned:** The literature review and interviews identified the following preliminary results:
- the documented linkage between HIV and all forms of child protection violations;
- the lack of clinical guidance to systematically detect, respond and prevent violence against children and the limited focus on physical and emotional abuse and neglect within HIV services ;
- resource limitations hindering an appropriate response to issues of violence against children within HIV services compounded by the declining resources for counselling;
- the need for robust and accountable systems to identify and support prevention and response to violence against children throughout the HIV continuum of care.
**Conclusions/Next steps:** There is widespread evidence of the linkage between HIV acquisition and treatment outcomes with violence and neglect. This linkage is not translating into routine identification and appropriate support to children throughout HIV services. Health and social workers require guidance and systems to work more closely together to detect, prevent and respond to the needs of children who have experienced or are at risk of physical, emotional, sexual abuse or neglect. The next step is for these findings to inform the development of guidance such as job aids in clinical and community settings.

## TUPED355

### VIOLENCE, ECONOMICALLY MOTIVATED SEX, AND SELF-REPORTED STI AMONG ADULT MEN IN FIVE COUNTRIES: POPULATION-BASED SURVEY FINDINGS FROM THE UN MULTI-COUNTRY STUDY OF MEN AND VIOLENCE IN ASIA AND THE PACIFIC

K. Dunkle, E. Chirwa, R. Jewkes
*South African Medical Research Council, Gender and Health Research Unit, Pretoria, South Africa*

**Background:** Violence and economically motivated sex are well established risk factors for HIV & STI among women, but too little is known about how these factors affect men's risk at the population level. Data on self-reported STI symptoms, while not diagnostic, allow for large-scale multinational data collection and analysis that is otherwise infeasible. We draw on data from the UN Multi-Country Study of Men and Violence in Asia and the Pacific to compare the relationship between violence, economically motivated sex, and STI risk across five countries.
**Methods:** Population-based household survey data from were collected from a total of 6,667 men aged 18-49 at sites across Bangladesh, Cambodia, China, Indonesia, and Bouganville, Papua New Guinea (PNG). Research methods were comparable across countries, including anonymous self-reporting of sensitive data.
**Results:** Self-reports of ever having STI symptoms/diagnoses varied by country: Bangladesh 54.7% (95%CI 51.5 - 57.7), Cambodia 28.0% (25.5 - 30.7), China 24.5% (21.7 - 27.4), Indonesia 13.3%
(11.7 - 15.0), PNG 36.2% (31.6 - 41.0). However, statistically significant adjusted odds ratios (aORs) from multiple logistic regression models showed consistent themes (controlling for the complex sample structure, age, lifetime partner numbers, substance use, and SES).

| Risk Factor | Bangladesh | Cambodia | China | Indonesia | PNG |
|---|---|---|---|---|---|
| Violence against female intimate partner | 1.20 (0.98 - 1.46) | 2.25 (1.75 - 2.92) | | | 1.98 (1.22 - 3.22) |
| Sexual violence against non-partner woman | 1.66 (1.13 - 2.44) | | 2.38 (1.35 - 4.21) | 1.85 (1.23 - 2.77) | |
| Gang membership | | 1.78 (1.10 - 2.90) | | 1.69 (1.11 - 2.53) | 1.90 (1.22 - 2.95) |
| Transactional sex with woman | 1.51 (1.04 - 2.20) | 1.81 (1.42 - 2.30) | | 1.49 (1.09 - 2.06) | 1.87 (1.21 - 2.89) |
| Sex with sex worker | 1.68 (1.19 - 2.39) | | | 1.67 (1.06 - 2.55) | 2.40 (1.41 - 4.10) |
| Depression score | 1.10 (1.07 - 1.13) | 1.04 (1.02 - 1.07) | 1.06 (1.01 - 1.11) | 1.11 (1.07 - 1.14) | 1.05 (1.01 - 1.09) |
| Childhood trauma score | | 1.04 (1.00 - 1.08) | 1.10 (1.03 - 1.17) | | |
| Gender Equitable Men (GEM) Score | | 0.97 (0.94 - 0.99) | | | 0.94 (0.90 - 0.98) |

*[aORs and 95% confidence intervals for self-reported STI]*

**Conclusions:** Across five Asian countries, men who report perpetration of violence (against intimate partners, against other women, or through gangs), or depression were more likely to self-report a lifetime history of STI. Buying economically

motivated sex (through transactional sex or sex work) increased men's risk in four countries. In two countries, more gender equitable men were less likely to report lifetime STI. These findings affirm perpetration of gender based violence and use of economic power as key determinants of men's sexual health across contexts and affirm the need to promote gender transformative approaches to STI and HIV prevention among men.

## TUPED356

### Analysing the effects of relationship level factors and perceived gender attitudes among female sex workers on experience of intimate partner violence in North Karnataka, South India

P. Javalkar[1], R. Prakash[1], S. Isac[2], T. Beattie[3], R. Thalinja[1], M. Collumbien[3], L. Heise[3], P. Bhattacharjee[2]
*[1]Karnataka Health Promotion Trust (KHPT), Research, Bangalore, India, [2]University of Manitoba, Centre for Global Public Health, Department of Community Sciences, Winnipeg, Canada, [3]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom*
*Presenting author email: prakashj@khpt.org*

**Background:** Like other women in India, female sex workers (FSWs) frequently experience violence from their intimate partners (IPs)-a reality that increases their risk of acquiring HIV or other sexually transmitted infections (STIs). Though research has established many risk factors for intimate partner violence (IPV), existing studies have focused mostly on the contribution of individual and community level factors to IPV risk. The effect of relationship-level factors and women's gender attitudes on violence, is less studied.
**Methods:** Data from a cross-sectional study conducted in 2014 with 620 FSWs in Bagalkot district of Karnataka, India was used to analyse the effect of relationship characteristics and gender-related attitudes on the likelihood of experiencing severe physical or sexual partner violence in the past 6 months. Partner violence was measured using a modified version of the Conflict Tactics Scale. Severe violence was defined as experiencing slapping pushing or shoving "many times," or any act of sexual or severe physical violence (acts c-f on the CTS) in the six months preceding the survey. Bivariate and multivariate methods were used for analyses.
**Results:** Results show that, overall, 24% FSWs experienced severe violence from their IPs in the past six months before the survey. In an intimate partner relationship, FSWs, who received social support from their IPs and had greater intimacy in their relationship were less likely to experience severe violence (AOR:0.49;p< 0.05 & AOR:0.35;p< 0.01, respectively) compared to their counterparts. Frequent alcohol use by a woman's male partner increased her likelihood of experiencing violence almost 10-fold (AOR: 9.71; p< 0.001). Additionally, a higher likelihood of experiencing severe violence was associated with the belief that men need sex and cannot control their urges (AOR: 1.96; p< 0.05), and counter-intuitively with the belief that forcing a woman to have sex against her will is a sign of disrespect (AOR: 2.86; p< 0.05).
**Conclusions:** Relationship level factors along with gender related attitudes emerged as significant predictors of violence, even after adjusting for the effects of individual level variables. Interventions to reduce HIV risk among sex workers should focus on improving the quality of their intimate partnerships and on shifting attitudes regarding forced sex.

## TUPED357

### Social network cohesion amplifies the effect of network gender norms on men's perpetration of intimate partner violence in Dar es Salaam, Tanzania

M. Mulawa[1], H.L. McNaughton Reyes[2], L. Kajula[3], S. Maman[2]
*[1]University of North Carolina at Chapel Hill, Health Behavior, Durham, United States, [2]University of North Carolina Gillings School of Global Public Health, Health Behavior, Chapel Hill, United States, [3]Muhimbili University of Health and Allied Sciences, Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of*
*Presenting author email: mulawa@live.unc.edu*

**Background:** Previous research has shown that social network-level gender norms are associated with men's perpetration of intimate partner violence (IPV) in sub-Saharan Africa. Theory and empirical evidence suggests that the effect of these norms on men's behavior may depend on the cohesion of the social networks. More cohesive networks, characterized by higher levels of trust and camaraderie, may also allow for faster flow of information.
This study drew on data from our on-going HIV and IPV prevention trial in Dar es Salaam, Tanzania with 1,106 sexually active men nested within 59 networks of randomly selected social groups called "camps." The purpose of this study was to assess the degree to which the social cohesion of networks moderated the relationship between camp-level gender norms and men's perpetration of physical IPV.
**Methods:** We modeled the interaction between network-level social cohesion and network-level gender norms on men's past-year IPV perpetration using a 2-level hierarchical logistic regression model. IPV perpetration was assessed using an adapted version of the WHO violence against women instrument. Network-level gender norms were computed by averaging responses among camp members to a 15-items adapted version of the Gender Equitable Men Scale. Network-level social cohesion was measured by averaging response among camp members to a 5-item adapted social cohesion scale. Our model included individual-level controls (demographic characteristics, childhood violence exposure, alcohol use, and attitudes towards gender roles) and camp-level controls (camp size and years of operations).
**Results:** Network-level social cohesion significantly moderated the effect of network-level gender norms of the odds of perpetration. Examination of simple slopes revealed that the positive relationship between inequitable network-level gender norms and men's perpetration was strongest in highly cohesive networks ($\gamma$= .25, p=.04) and not significantly different from zero in networks with average or low levels of cohesion.
**Conclusions:** Interventions seeking to reduce IPV should consider efforts to simultaneously increase cohesion within networks while striving to make gender norms more equitable. Transforming gender norms may not be as effective in reducing men's perpetration of IPV if it is done within socially fragmented networks compared to networks that are more cohesive.

## TUPED358

### Understanding and addressing violence among key populations to offer effective HIV programming

R. Dayton[1], A. Olawo[2], G. Morales[1], T. Miller[1], J. Walimbwa[3], A. Gikari[4], J. Ngugi[5], M. Odhiambo[6], L. Dalziel[6], L. Nthei[5]
*[1]FHI 360, Durham, United States, [2]FHI 360, Nairobi, Kenya, [3]Gay and Lesbian Coalition of Kenya (GALCK), Nairobi, Kenya, [4]Health Support for Addictions Prevention and Treatment in Africa (SAPTA), Nairobi, Kenya, [5]Health Options for Young Men on HIV, AIDS and STIs (HOYMAS), Nairobi, Kenya, [6]Jinsiangu, Nairobi, Kenya*
*Presenting author email: rldayton@fhi360.org*

**Background:** Violence affects HIV risk, testing uptake, and treatment adherence. Key populations (KPs) - men who have sex with men (MSM), people who inject drugs (PWID), sex workers (SWs), and transgender people - face high levels of violence, but relatively little is done on this important issue. Understanding local experiences of and responses to violence can inform effective HIV programming.
**Methods:** As part of a gender analysis to inform KP programming in Kenya, we conducted a desk review and 59 qualitative, in-depth interviews with KP representatives, government officials, program managers and funders, and healthcare workers (HCWs). Questions covered types of violence that KPs experience, responses to violence, and potential connections between HIV and violence response services. Expanded notes from the interviews were analyzed for recurring themes per KP.
**Results:** Respondents described widespread violence against all KPs. Within KPs, MSM perceived to be the primarily anally receptive partner; transgender people currently transitioning; and younger, new, and transgender SWs were believed to experience the most violence. Across all KPs, individuals living with HIV were perceived to be at greater risk. These findings are reinforced by the literature. Yet, respondents stated HCWs do not routinely screen for violence and do not provide counseling on violence, including when discussing strategies for disclosure with HIV-positive clients. Furthermore, all respondents agreed that most KP members are unlikely to report violence but desperately need access to violence response services. They recommended increasing violence response services at community-based organizations (CBOs) - including counseling and safe spaces - and strengthening the links between clinics and CBOs through education and referral by HCWs and peer accompaniment for referred services.
**Conclusions:** Violence response services are a vital part of effective KP HIV programming, particularly because violence is often most common among KPs living with HIV or with the greatest HIV risk. Yet they are largely unavailable in Kenya and elsewhere. There are clear opportunities to build stronger HIV response services at CBOs and strengthen links between violence response and HIV services. Stronger violence response within HIV programs could protect KPs' human rights while meeting KPs' holistic needs.

## TUPED359

### HIV-RISK BEHAVIORS OF MEN WHO PERPETRATE INTIMATE-PARTNER VIOLENCE IN RAKAI, UGANDA

M. Mullinax[1], X. Song[2], S. Grilo[2], J. Wagman[3], S. Mathur[4], T. Lutalo[5], J. Santelli[2]
*[1]Columbia University, HIV Center for Clinical and Behavioral Studies, New York, United States, [2]Columbia University, Heilbrunn Department of Population & Family Health, New York, United States, [3]University of California, San Diego, San Diego, United States, [4]Population Council, Washington, D.C., United States, [5]Rakai Health Sciences Program, Kalisizo Town, Uganda*
*Presenting author email: js2637@columbia.edu*

**Background:** Across cultural settings the epidemics of HIV and intimate partner violence (IPV) are linked; violence victimization is highly prevalent among women with HIV. However, much of the research on violence and HIV is cross-sectional, and does not include information on violence perpetration from the perspective of men. This study investigated associations between male perpetration of physical and sexual IPV and select HIV risk and protective behaviors and outcomes in rural Uganda.
**Methods:** We used data from five rounds (2004-2013) of the Rakai Community Cohort Study (RCCS), an on-going HIV surveillance cohort that enrolls ~14,000 consenting men and women 15-49 years on a semi-annual basis in Rakai, Uganda. We categorized the male physical and the male sexual violence variables into three categories (no violence, only verbal, and physical), and considered the proportional odds models to estimate their association with HIV-related risk factors, while accounting for the repeated measurements of observations through robust estimation. The HIV-related risk factors include alcohol use before sex, inconsistent condom use, and number of sex partners, medical circumcision, and HIV prevalence. The male sample size is 21,157.
**Results:** A small percent of men (17.3%) reported only verbally abusing or shouting (n=3,664), and even fewer men (10.4%) reported physically abusing (e.g. pushing, slapping, punching) (n=2,208) their wife or primary partner in the past year. Few men reported using verbal (1%) or physical threats (3.1%) to force their partner to have sex with them (n=23; 650, respectively). Men who reported perpetrating physical abuse and/or men who reported sexual abuse were more likely to report drinking alcohol before sex, inconsistent condom use, and having a greater number of sexual partners in the past year and lifetime, relative to men did not perpetrate IPV. Men committing IPV were less likely to have accessed male medical circumcision than men who did not report violence. IPV perpetration was not significantly associated with HIV status.
**Conclusions:** Men reporting acts of physical and sexual abuse also reported higher rates of HIV risk behaviors. HIV prevention efforts must also address prevention of IPV with men.

## TUPED360

### INTERVENTIONS IN THE PRIVATE: INTIMATE PARTNER VIOLENCE AND REDUCING VULNERABILITIES

D. Bhattacharya, S. Karkal
*Swasti Health Resource Centre, Bangalore, India*
*Presenting author email: deya@swasti.org*

**Background:** The concept of crisis-response within public spaces to combat the vulnerability of female sex workers (FSWs) to violence, and in turn to reduce their vulnerability to HIV/AIDS infections, was a key addition to the HIV programme during phase I and II of the Avahan India AIDS Initiative. This strategy emphasized the ways of countering, negotiating and combating violence perpetrated by agents of law enforcement, and ensuring that the external environments surrounding the FSWs were secure and safe. This has, over the years, led to the assumption that FSWs feel safe and protected in private spaces.
**Description:** Under the aegis of the Phase III of the Avahan Initiative, the strategy on violence has included prevention in addition to redressal and has made efforts to understand the current experience of violence from different people. The Avahan Initiative looks to 84 Community Organizations (COs) in five states of India to implement these approaches.
Individual data on violence faced indicates that of the total number of incidents faced in the previous six months, 41.49% are incidents of intimate partner violence. Out of this, only 58.41% incidents were reported (to authorities or peers). The data gives vital insights: firstly, violence has changed spheres and, this calls for interventions to focus on private spaces; spaces that are often away from the reach of donors, implementers and activists; secondly, the gaps in reporting cases of intimate partner violence are staggering.
**Lessons learned:** This paper predicts that a behavioural and attitudinal shift in the perception and combating of intimate partner violence is possible through the utilization and layering of four holistic approaches:
(i) awareness generation;
(ii) prioritization of the most vulnerable in the programme;
(iii) strengthening of the extant system of crisis-response; and
(iv) advocacy with stakeholders.
**Conclusions/Next steps:** The public realm is the domain of politics - where FSWs have negotiated power in the earlier phases of the Initiative, while the private sphere envelops within itself a secluded 'zone of privacy' which the interventionist programmes, including Avahan, has not been able to pervade. Vulnerability to violence in both spheres should be equally prioritized and effectively addressed.

## TUPED361

### BENEFIT OF STEPPING STONES FOR PREVENTION OF INTIMATE PARTNER VIOLENCE AMONG MEN DEPENDS ON PARTICIPANT'S USE OF VIOLENCE BEFORE BASELINE: SECONDARY ANALYSIS OF DATA FROM THE COMMUNITY RANDOMISED CONTROLLED TRIAL

K. Dunkle, R. Jewkes, E. Chirwa, N.J. Shai
*South African Medical Research Council, Gender and Health Research Unit, Pretoria, South Africa*

**Background:** The Stepping Stones community randomized controlled trial in South Africa demonstrated reduced HSV-2 incidence and reduced perpetration of intimate partner violence (IPV) among young male participants. Here, we explore factors that predicted IPV incidence over 2 years of follow-up and the possibility of differential intervention impact on different participants.
**Methods:** We analyzed data from 1,132 young South African men who participated in the 2 year, cluster-randomized controlled trial of Stepping Stones. We used hierarchical linear modeling to explore changes in self-reported perpetration of IPV over time. The intervention was treated as cluster-level variable; childhood experiences, household economic status, and pre-baseline IPV perpetration were treated as person-level variables. All other potential risk factors -- participation in transactional sex, having multiple or concurrent sexual partners, perpetration of non-partner sexual violence, depression, relationship conflict, and substance use -- were treated as time-varying. We tested all theoretically-relevant potential interaction effects.
**Results:** Men who received the Stepping Stones intervention reported reduced perpetration of IPV over time, while those who experienced childhood trauma and those who had perpetrated IPV before the start of the study increased IPV perpetration. Alcohol problems, depression, and perpetration of sexual violence against non-partners were all risk factors for increased perpetration of IPV. There were significant differences among men who reported perpetration of IPV before the start of the study. Among these men, the intervention showed no effect, and the effects of alcohol and non-partner sexual violence on increasing risk were significantly attenuated.
**Conclusions:** This analysis affirms that many of the risk factors hypothesized from cross-sectional research lead to increased perpetration of IPV among young men, specifically: childhood trauma, alcohol problems, depression, and sexual violence against non-partners. It also affirms the preventive benefit of the Stepping Stones intervention. However, it reveals significant differences in patterns of risk and benefit depending on whether men reported perpetration of IPV before the beginning of the study. This affirms the urgent necessity of effective primary prevention of IPV among young men, and further suggests that new strategies are required to prevent on-going perpetration among young men who have already engaged in IPV.

## SEXUALITY AND GENDER-BASED VIOLENCE AND EXPLOITATION, INCLUDING IN CONFLICT SETTINGS

### TUPED362

#### HIGH REPORTS OF VIOLENCE IN ADULTHOOD AMONG WOMEN LIVING WITH HIV IN CANADA AND AFFILIATED RISK FACTORS

C. Logie[1], E. Ding[2], A. de Pokomandy[3,4], P. O'Campo[5,6], N. O'Brien[3], S. Greene[7], W. Tharao[8], S. Jabbari[2], A. Carter[2,9], K. Proulx-Boucher[4], A. Carlson[10], S.Y. Yin[2,9], M. Desbiens[8], K. Webster[9], D. Dubuc[4], P. Sereda[2], G. Colley[2], R. Hogg[2,9], A. Kaida[9], A. Lacombe-Duncan[1], M. Loutfy[5,10,11], CHIWOS Research Team
*[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, ON, Canada, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]McGill University, Medicine, Montreal, Canada, [4]McGill University Health Centre, Montreal, Canada, [5]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [6]St. Michael's Hospital, Centre for Research on Inner City Health, Toronto, Canada, [7]McMaster University, Social Work, Hamilton, Canada, [8]Women's Health in Women's Hands, Toronto, Canada, [9]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada, [10]Women's College Hospital, Women's College Research Institute, Toronto, Canada, [11]University of Toronto, Faculty of Medicine, Toronto, Canada*
*Presenting author email: ashley.lacombe.duncan@mail.utoronto.ca*

**Background:** Worldwide women experience high rates of violence related to entrenched gender inequities. This violence may be exacerbated for women with HIV, who experience HIV-related stigma among other forms of marginalization. We assessed the prevalence of, and factors associated with, experiencing violence in adulthood among women with HIV enrolled in a Canadian cohort.
**Methods:** Baseline survey data were analyzed for women with HIV (≥16 years) enrolled in a community-based research cohort study in British Columbia (BC), Ontario (ON), and Québec (QC). Violence was assessed through self-reported experiences of physical, sexual, verbal, or emotional violence in adulthood (≥16 years). Multivariable logistic regression was used to identify factors associated with having experienced any form of violence in adulthood.
**Results:** Of 1322 participants, (25%-BC, 50%-ON, 25%-QC) the median age was 43 (IQR=36-51) years and 22% identified as Indigenous, 28% African, Caribbean or Black (ACB), 42% white/Caucasian, and 8% other. Most (80%) participants reported ever experiencing any adulthood violence, including physical (62%), sexual (45%), verbal (74%), and emotional (46%). 1004 participants with complete data on violence were included in the multivariable analysis. Factors significantly associated with having experienced any adulthood violence included: recreational drug use in the past 3 months (AOR: 17.89, 95% CI: 4.29-74.59); post-traumatic stress disorder (PTSD) (AOR: 2.27, 95% CI: 1.49-3.47); gender discrimination (AOR: 1.05, 95% CI: 1.02-1.07); and age (AOR: 1.02, 95% CI: 1.00-1.04). Participants taking antiretrovirals (AOR: 2.70, 95% CI: 1.69-4.34), Indigenous women (AOR: 1.89, 95% CI: 1.10-3.27) and Caucasian women (AOR: 1.91, 95% CI: 1.26-2.89) in comparison with ACB women, were also more likely to report adulthood violence.
**Conclusions:** Four out of five women with HIV in this study experienced violence in adulthood, with high rates of physical and sexual violence. Experiences of adulthood violence were associated with PTSD symptoms and recreational drug use, highlighting the need for trauma-informed and harm reduction approaches to engage women in the HIV care continuum. Women who experience gender discrimination and other forms of social exclusion, including women who use drugs and Indigenous women, reported disproportionate rates of violence. Intersectional approaches that address gender discrimination are crucial to reduce gender-based violence experienced by women with HIV.

### TUPED363

#### NUH GUH DEH! (DON'T GO THERE): END SEX WITH THE GIRL CHILD/END HIV AMONG ADOLESCENT GIRLS IN JAMAICA

P. Watson[1], N. Condell[2]
*[1]EVE for Life, Kingston, Jamaica, [2]UNICEF Jamaica, Kingston, Jamaica*
*Presenting author email: pwatson@eveforlife.org*

**Background:** Eve for Life's programme to support adolescent girls living with HIV in Western Jamaica revealed that 45% of clients reported being forced at first sex and contracting HIV as a result. The Jamaica Reproductive Health Survey 2008 report that 20% of young women below 19 report rape as first sex. Despite a possible linkage between HIV transmission among young girls and child sexual abuse (CSA), these remain largely unexplored in the national response. Funded by the UN in Jamaica and the British High Commission, a campaign was implemented to raise awareness about the significant and long term consequences of SA of young girls and the links to HIV and to stimulate dialogue and action (reporting abuse) on the issue of child sexual abuse.
**Description:** The campaign utilised a multi-pronged approach, combining empowerment sessions, media, person-to-person and community interactions around SA of girls and HIV. 13 survivors of CSA participated in an empowerment programme. They received counselling, learnt about gender and HIV issues and communication skills. They developed digital stories on their experience and HIV and the diary of one survivor was published. Between October 2014 and October 2015, a community and media intervention was launched using the material produced to address the SA of girls as an HIV prevention strategy.
**Lessons learned:** The campaign highlighted the value of community mobilisation around SA and HIV issues. It resulted in 4961 persons reached in community forums, schools and one-on-one interactions at the community level; 25 articles published in local newspapers; 8 radio and 7 television interviews and two documentaries aired on local television.
**Conclusions/Next steps:** CSA is increasing in Jamaica. Girls aged 15 - 17 years account for 63% of all SA cases reported to the Office of the Children's Registry. This co-relates with the trends in the national HIV and AIDS data where girls aged 14 - 19 years old are four times more at risk of contracting HIV than boys the same age. The high prevalence of both HIV and sexual abuse of girls points to the need to bridge programmatic responses to address HIV.

### TUPED364

#### EXPLOITATIVE SEX WORK AMONG MSM AND TRANSGENDER WOMEN IN SOUTH ASIA: VULNERABILITY TO SEXUAL ABUSE AND HIV

P. Prabhughate[1], P. Dhall[2], J. Varghese[1], R. Verma[3]
*[1]International Center for Research on Women, Research, Mumbai, India, [2]Varta, Kolkatta, India, [3]International Center for Research on Women, Research, Delhi, India*
*Presenting author email: pprabhughate@icrw.org*

**Background:** Studies on how gender based violence (GBV) exacerbate HIV related vulnerabilities among Men Who have Sex with Men (MSM) and Transgender (TG) Women especially in cross-cultural contexts are rare. This paper highlights pathways between GBV and HIV-related vulnerabilities of MSM and TG women engaged in sex work in India, Afghanistan and Pakistan- three different cultural contexts yet characterized by similar patriarchal structures and unequal gender norms. This paper presents data from three countries conducted as a part of a seven-country South Asian regional study supported by UNDP.
**Methods:** A total of 10 FGDs were conducted with MSM and TG women in Afghanistan, India, and Pakistan using case vignettes to elicit narratives of GBV among study participants along various situations in the lives of MSM and TG women. We analyzed data using a coding tree emergent from the reading of descriptive data, and used Atlas-ti to identify the key themes and various linkages including those structural issues that underlie the pathways.
**Results:** Analyses reveal that GBV is pervasive in the lives of MSM and TG women and is emergent from multiples structures such as family, community, intimate relationships, health and law enforcement institutions, including police. Both internalized and experienced stigmas characterize the pathways through which MSMs and TGs are denied their rights and discriminated. All pervasive denial and discrimination is rooted in the strong patriarchal structures and norms around what is normal and finds multiple expressions. MSM and TG engaged in sex work report greater sexual violence associated with lack of ability to negotiate safety, unavailability of condoms, vulnerability to gang rape, blackmail and lack of access to forums for redress for violence. Results also show that not belonging to a network, being effeminate, being young and not having sources of gainful employment increases dependence on exploitative sex work and thereby vulnerability to violence, mental ill health and exposure to risky sex.
**Conclusions:** Interventions must address institutions and norms that nurture and perpetuate GBV. They should strengthen community networks, involve perpetrators of violence, ensure economic inclusion and advocate for better protection and mitigation mechanisms against GBV rather than narrow medicalized approaches to HIV prevention.

#### SEXUAL VIOLENCE AND RAPE IN RUSTENBURG, SOUTH AFRICA: IMPLICATIONS FOR SERVICE PROVISION AND PREVENTION

A. Shroufi, S.J. Steele, K. Phillips, A. Mews, J. Hill, P. Mazuru, A. Luczynska, K. Duncan, G. Van Cutsem
*Médecins Sans Frontières, Cape Town, South Africa*
*Presenting author email: amir.shroufi@doctors.org.uk*

**Background:** Rustenburg Municipality (population 550,000) is one of Africa's fastest growing cities, and as the country's platinum mining capital, attracts many migrant workers. Bojanala district, in which Rustenburg is situated, has an HIV prevalence

of 35% among antenatal women; its rape prevalence has not previously been reported.
HIV transmission is higher during forced sex (particularly child sexual abuse) than consensual sex, which can exacerbate transmission in areas with concurrent epidemics of HIV and rape. Here we quantify prevalence of sexual violence and rape in Rustenburg.
**Methods:** In this cluster randomized household survey fieldworkers collected information from women aged 18-49 on their experience of rape, as well as associated behaviors and attitudes. The study population and prevalence of rape (forced sex or sexual acts) are described.
**Results:** The average age of participants (n=1,123) was 32 years and 44% had completed secondary school or higher. The majority of women grew-up in South Africa; however, 62% grew-up in a rural area/village outside of the Rustenburg Municipality.
Life-time prevalence of rape of 33%, with 10% experiencing at least one rape by a sexual partner, and 8% experiencing at least one rape by a non-sexual partner before the age of 15 years. The reported incidence of rape was 53 per 1000 person years.
Among those who had been raped, 17% reported seeking legal services after a previous experience of rape.
**Conclusions:** We report an extremely high prevalence of sexual violence, including rape by partners, non-partners, and among children in the platinum belt of Rustenburg, making women vulnerable to negative health outcomes, including HIV acquisition. Reported access to legal and comprehensive medical services is particularly poor in this highly vulnerable population, highlighting the need for improved service delivery.
The HIV/AIDS and rape epidemics share similar risk factors and challenges to access, exacerbating harm. A coordinated local and national approach to the prevention, management, and planning of both is necessary.

## TUPED366

### ASSOCIATIONS BETWEEN ADOLESCENT EXPERIENCES OF VIOLENCE IN MALAWI AND GENDER-BASED VIOLENT ATTITUDES AND BEHAVIOURS

V. Ameli[1], B. Ushie[2], F. Meinck[1], A. Munhali[3], L. Langhaug[4]
*[1]Centre for Evidence-Based Intervention at University of Oxford, Social Policy and Intervention, Oxford, United Kingdom, [2]Regional Psychosocial Support Initiative (REPSSI), Ibadan, Nigeria, [3]Centre for Social Research, Zomba, Malawi, [4]Regional Psycho Social Support Initiative (REPSSI), Harare, Zimbabwe*
*Presenting author email: vira.ameli@spi.ox.ac.uk*

**Background:** Emotional, physical, and sexual adolescent maltreatment in the home or at school have been found to be key predictors of gender-based-violence (GBV). GBV has strong links to the HIV epidemic in sub-Saharan Africa. The objective of this research was to measure the prevalence of exposure to violence among Malawian adolescents, and to test the hypotheses that such exposures are associated with prevalent gender-based violent attitudes and behaviours, which continues the cycle of violence and increased HIV transmission.
**Methods:** We analysed questionnaires collected from 561 primary school pupils, aged 10-19, in 1 urban and 2 rural districts of Malawi. Participants were 281 girls and 280 boys who assented following caregiver consent. Using SAS, the data was stratified by gender, and logistic regression analysis was performed, adjusting for sociodemographic differences in the final parsimonious models.
**Results:** Both girls and boys had witnessed domestic violence (28.5% & 29.6%), experienced emotional abuse at home (23.1% & 22.9%), physical abuse at home (28.1% & 30.4%), physical abuse at school (42.4% & 36.4%), and bullying (33.8% & 39.6%).
Girls who internalized violent attitudes towards women were more likely to have experienced emotional abuse (OR 2.1), and physical abuse at school (OR 1.7). Condoning rape was associated with physical abuse at school (OR 1.9). Participation in bullying was associated with experiencing emotional abuse at home (OR 4.5).
Among boys, violent attitudes towards women and condoning rape were not associated with violence exposure. Participation in bullying was associated with prior experience of being bullied (OR 2.9), and physical abuse at school (OR 2.7).
**Conclusions:** These results indicate that - among girls, but not boys - internalized violent attitudes towards women and acceptance of rape are linked to violence exposure in homes and schools. The findings can inform programmes designed to reduce violence victimization among Malawian girls. Some effective interventions could be microfinance loans, programs designed to reduce sexual violence and IPV in homes, parenting programmes, and enforcing strict prohibitive measures on physical violence and punishments in schools. All of these programs could be effective in reducing gender-based-violence and impeding its contribution to new HIV infections.

## TUPED367

### INTERPERSONAL AND STRUCTURAL FACTORS OF NON-CONDOM USE WITH INTIMATE PARTNERS AMONG SEX WORKERS IN CONFLICT-AFFECTED NORTHERN UGANDA

A. Ferguson[1], J. Birungi[2], M. Akello[2], P. Duff[1,3], P. Nguyen[1], G. Muzaaya[2], K. Shannon[1,3]
*[1]Gender and Sexual Health Initiative, BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]The AIDS Support Organization (TASO), Gulu, Uganda, [3]University of British Columbia, Department of Medicine, Vancouver, Canada*
*Presenting author email: fe3@ualberta.ca*

**Background:** Women sex workers (SWs) in sub-Saharan Africa have among the highest HIV burden, and similar pregnancy intentions to the general population of women of reproductive age, yet we know less about male condom use with intimate non-paying partners than with clients. Understanding the social and structural contexts of non-condom use in intimate partnerships is critical given shared pathways for HIV and pregnancy, particularly in the absence of other biomedical interventions (e.g. antiretroviral therapy, and hormonal contraceptives).
**Methods:** Drawing on a community-based project in partnership with The AIDS Support Organization (TASO) Gulu, SWs, and other community organizations, we conducted interview-administered questionnaires embedded in SW/peer-led outreach to bars, hotels, and truck stops across Gulu, and voluntary HIV testing with 400 women SWs between 2011 and 2012. Multivariable logistic regression was used to examine factors associated with non-condom use at last sex with SWs' main/most recent intimate partner.
**Results:** Of the 379 women SWs with an intimate partner, 150 (39.6%) reported non-condom use at last sex with their most recent intimate partner. The median age of women was 21 years (IQR= 19.0 - 26.0), with 63.3% having completed less than primary education. One-third (32.5%) were living with HIV, and the majority (69.9%), were mothers supporting one or more children. In multivariable analysis, having low sexual relationship power (Adjusted Odds Ratio (AOR) 3.40, 95% Confidence Interval (CI) 1.05 - 2.68), harassment by agents of the state (police or military) (AOR 1.96, 95% CI 1.23 - 3.15), and hormonal contraceptive use (AOR 1.68, 95% CI 1.77 - 6.53), were independently associated with non-condom use with intimate partners.
**Conclusions:** While non-condom use may be reflective of pregnancy intentions and a higher degree of intimacy within intimate partnerships, this study highlights how gendered power dynamics, both at the interpersonal (low sexual power and decision-making with intimate partners) and structural levels (harassment by policy and military), shape condom use with intimate partners of SWs in a post-conflict setting. Policy reforms to ensure the protection of SWs' health and human rights, and monitoring and redress of abuse in conflict-settings remain critical, alongside gender transformative approaches to HIV prevention, treatment, and care.

# MEDIA, CULTURAL AND RELIGIOUS REPRESENTATIONS OF HIV AND AIDS

## TUPED368

### THE NEWS MEDIA DISCOURSE SURROUNDING HIV IN THE U.S. DEEP SOUTH: NEGATIVITY, FEAR OF CONTAGION, AND OSTRACIZATION

M.V. Dabbah[1], E. Klukas[2], A. Dabbah[3]
*[1]UMMA Community Clinic, Administration, Los Angeles, United States, [2]The Data Edge, Bangkok, Thailand, [3]AOL, San Francisco, United States*
*Presenting author email: dr.miriam.y.vega@gmail.com*

**Background:** Thirty years after the first reported HIV case, the overall number of new US diagnoses continues to fall. As a result, the media focus on HIV has markedly decreased arguably leading to a false sense amongst individuals-at-large that HIV is no longer an urgent health issue to address. American news media has also experienced a rapid transformation through changes in technology impacting the public information environment. These changes create a pressing need for advocates to understand how HIV is discussed and portrayed in the public discourse.
**Methods:** Drawing on anthropological tools, this study conducted textual analysis of 161 news media stories throughout seven Deep South states (where HIV incidence rate is highest) from 2010-2014 found through Google searches, downloaded and coded. There was a minimum of 20 articles per state. We coded for media context, level of interactivity, and content of the stories regarding ideology, stigmatizing and emotional attributes, and policy focus.
**Results:** Only 7% of the articles were on the "front page." Over 26% of the articles were written due to the release of a data set. In terms of policies, 17% discussed criminalization. The shorter the articles in terms of word length, the more conservative they were rated by the coders (on a scale of 1 being extremely liberal and 7 extremely conservative) and those data-driven articles were rated as more conservative (M =3.86). A plurality of the articles (42%) were negative in tone. The top coded

emotions were: skepticism, fear and contempt. In South Carolina (where there are active HIV-criminalization cases), there were more references in the articles to the contagion/danger posed to others by HIV. Lastly, ostracization was often noted in the HIV-related articles as a repercussion. Overall, 80% of the articles allowed for comments to be posted; of which 56% had posted comments. The range of article-shares was from 0 to 11,900.
**Conclusions:** Ample evidence shows that media articles help shape attitudes and beliefs, educate the public and can help mold policies. These study findings make it imperative that we continually educate media on HIV and stigma as we also work on the ground with high-risk populations.

## Experiences and impacts of HIV-related stigma

### TUPED369

### 'We don't want to be noticed collecting drugs': the effects of stigma and discrimination on adherence to medication amongst people living with HIV in Tiv Land, North Central Nigeria

G.A. Timiun[1], T. Scrase[2]
*[1]Benue State University, Sociology, Makurdi, Nigeria, [2]Australian Catholic University, Sociology, Melbourn, Australia*
*Presenting author email: gatimiun@gmail.com*

**Background:** In spite of recognising stigma as a factor impeding the public utilisation of HIV counselling, testing, and treatment services in Nigeria, gaps in knowledge still exist concerning the impact of stigma and discrimination on adherence to medication amongst people living with HIV (PLWH). This study examines the impact of stigma and discrimination on adherence to medication amongst people living with HIV in Nigeria.
**Methods:** A sample of 1,621 (864 women; 757 men) respondents was collected from 2 clinics (Mkar; Aliade) and other 2 locations (Jyovkundan; Udei) using multi-stage and purposive sampling methods. An eight page questionnaire with closed and open ended questions was used for quantitative data collection amongst 805 HIV seropositive clinic attendees and 796 HIV seronegative individuals. SPSS (version 21) was used for quantitative data analysis. Twenty (20) respondents (10 HIV seropositive; 10 HIV seronegative) participated in in-depth interviews which were recorded.
**Results:** They were 46.3% men and 53.7% women. Those between 30 and 34 years were 23.4%, while those between the ages of 25 and 29 years were 21.9%. Approximately 55% were married, 17.9% were either divorced or separated, while the single and those cohabiting were 26.2% and 0.6% respectively. Generally, their income was low, 70.7% were earning less than N25, 000 (approximately $125 USD) per month. All respondents were on drugs. Some of the HIV patients are isolated, they sit, eat and drink water in personalised seats and plates; uncomplimentary statements are made about them. In reaction to stigma and discriminations, some of them avoid public places, if possible, they travel long distances away from their immediate community to collect drugs, to avoid been noticed around the centers. Thus, they sometimes miss taking drugs regularly as prescribed, suffer depression and die.
**Conclusions:** Not only that stigma and discrimination hinder public utilisation of HIV counselling, testing and treatment services, it impede adherence to medication amongst people living with HIV in Nigeria. More efforts should be made to create awareness to reduce stigma and discrimination of HIV patients, while augmenting their income to overcome the challenges of visiting far health centers to collect drugs, should the need arise.

### TUPED370

### The predictive power of stigma on substance use and sexual risk behaviors among people living with HIV/AIDS in Southwest China

Y. Zhou[1], C. Zhang[2], X. Li[3], Y. Liu[2], S. Qiao[3], Z. Shen[1], Y. Chen[1]
*[1]Guangxi CDC, Nanning, China, [2]Vanderbilt University, Medicine, Nashville, United States, [3]University of South Carolina, School of Public Health, Columbia, United States*
*Presenting author email: xiaoming@mailbox.sc.edu*

**Background:** HIV stigma against people living with HIV/AIDS (PLWHA) is prevalent. The impact of HIV stigma has various effects on their risk behaviors during their sexual episodes as well as on substance use among PLWHA. In this study, we explored the predictive power of HIV stigma on substance use and sexual risk behaviors among male and female PLWHA in China.
**Methods:** A total of 2987 PLWHA were recruited via a pre-established sampling scheme. Approximately 10% of cases were selected from top 12 study sites in terms of HIV cases in Guangxi. In order to explore the predictive power of the stigma on risk behaviors among PLWHA, we first categorized the score of HIV stigma based upon its quantiles. We examined demographics, psychosocial wellbeing and risk behaviors across these quantiles by employing Chi-square (for categorical variables) and ANOVA (for continuous variables) with trend tests. We further assessed the predictive power of HIV stigma on risk behaviors (substance use and risky sexual behaviors) using restricted cubic splines in the multivariate regression analyses. A gender-specific stratum analyses were also conducted to explore the predictive power of HIV stigma between male and female PLWHA.
**Results:** The bivariate analyses and trend testes revealed that both psychosocial distress and behaviors of substance use increased significantly among PLWHA with higher stigma. The restricted cubic spline model indicated a possible threshold for the risk of smoking and drug use among PLWHA. PLWHA with 50th percentile stigma score were more likely to report smoking (β=0.08,95%CI=0.02, 0.14), and drug use (β=0.10,95%CI=0.01, 0.19). The highest percentile of HIV stigma only marginally increased the numbers of sex acts (β=0.60,95%CI=-0.03, 1.23) and sexual partners (β=0.77,95%CI=0.00, 1.53).
**Conclusions:** Our analysis found HIV stigma had a stronger predictive power on substance use, but not a good predictor for sexual risk behaviors. Health prevention programs should target to PLWHA with higher stigma for their substance use problems. Further research should be conducted to explore risk factors for sexual risk behaviors among PLWHA to eliminate the potential of them as the source of the HIV transmission in China as well as other settings worldwide.

### TUPED371

### Resolved and unresolved issues among people living with HIV in Japan after 10 years of advancement in medical environment: results from nationwide multicenter surveys from 2003 to 2013

T. Ohtsuki[1], C. Wakabayashi[2], Y. Ikushima[1], M. Yamaguchi[3], M. Tarui[1,4],
Research on Support for PLHIV and DU in Regional Communities
*[1]PLACE Tokyo, Tokyo, Japan, [2]Saitama Prefectural University, Saitama, Japan, [3]Bunan Hospital, Saitama, Japan, [4]Keio University, Tokyo, Japan*
*Presenting author email: ohtsuki@ptokyo.org*

**Background:** Advances in ART over the past 10 years have changed the recuperation of people living with HIV (PLHIV) in Japan drastically. Yet, has "Living with HIV" really been easier? Nationwide research on the quality of life of PLHIV has been conducted every five years. The latest one was done in 2013, and a comparison was made in order to track a trend in the living conditions of PLHIV since 2003.
**Methods:** Anonymous, self-completed questionnaires were distributed to 2,473 outpatients at 31 leading AIDS care hospitals in Japan. The survey period was from July 2013 to April 2014. The same method was adopted in the 2003 (783 outpatients at 5 hospitals) and 2008 (1,813 outpatients at 33 hospitals) studies.
**Results:** Among 1,469 responses returned by mail, 94.1% were men and 5.1% were women in 2013. Response rate was 59.4% (72.3% in 2003 and 66.4% in 2008). There is a significant increase in the rate of once-daily dosage of HIV medication (from 3.8% in 2003 to 56.6% in 2013) and once every 2-3 months of healthcare provider visits (from 37.2% to 73.0%). More people showed intentions to work (37.2% in 2003, 49.1% in 2008, and 58.7% in 2013 said, "Do not want limitations on the way of working"). The ratio of non-working population of PLHIV stayed at the same level over the years (20-25%). The percentage of PLHIV who left former job following positive HIV diagnosis was 37.6% in 2003, 42.0% in 2008, and 40.5% in 2013. In 2003, 27.5% had come out as HIV positive at work, yet the rate slightly decreased to 21.0% in 2013. The 2013 study showed that 73.4% experienced "thinking of an excuse for not disclosing HIV status" and 10.8% "unwillingly leaving their job due to HIV."
**Conclusions:** The treatment burden has been greatly alleviated by therapeutic advances. Nevertheless, there are still stressors that hinder PLHIV from participating fully in society. Some people try to solve workplace issues through changing their job, not through consulting with someone at work. Appropriate measures are needed to foster an understanding of HIV/AIDS and to remove stigma at all levels of society including workplaces.

## TUPED372

### CREATING CONTEXTUALIZED FILMS THROUGH COMMUNITY ENGAGEMENT TO ADDRESS HIV-STIGMA IN WESTERN KENYA

C.T. Lewis[1], J. Dickerson-Putman[2], C. McAteer[3], J. Aluoch[4], E. Ngare[5], C. Odhiambo[6], W. Nyandiko[4,7], R. Vreeman[3,7,8]
*[1]Indiana University, School of Informatics and Computing, Department of Human-Centered Computing, Indianapolis, United States, [2]Indiana University School of Liberal Arts, Anthropology, Indianapolis, United States, [3]Indiana University School of Medicine, Department of Paediatrics, Indianapolis, United States, [4]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [5]Moi University, Department of Literature, Theatre and Film Studies, Eldoret, Kenya, [6]Moi University, Department of Literature, Theatre and Film Studies, Eldoret, United States, [7]Moi University, College of Health Sciences, School of Medicine, Department of Child Health and Paediatrics, Eldoret, Kenya, [8]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, United States*
*Presenting author email: lewisct@iupui.edu*

**Background:** HIV-stigma impacts HIV-infected adolescents' psychosocial development and how they navigate their social surroundings. We sought to better understand the experiences of HIV-infected adolescents in western Kenya with HIV-stigma and to subsequently develop culturally sensitive films to reflect those experiences.
**Methods:** A US and Kenyan collaborative team conducted a qualitative study investigating the social and cultural impact of HIV-stigma on adolescents living with HIV. Our participatory research strategy included focus group discussions with HIV-infected adolescents and with caregivers of children with HIV, followed by in-depth interviews with participants, including HIV-infected adolescents and various community members in Eldoret, a mid-sized town in western Kenya (e.g. shop owners, pastors, teachers). Interviews, conducted in Kiswahili or English, were translated and transcribed. Applied thematic analysis was used to identify themes reflecting the lived experience of stigma. A participatory advisory board, comprised of research investigators, HIV disclosure counselors, and HIV-infected adolescents, drew upon these culturally contextualized themes to create narrative scripts for films focused on HIV-stigma.
**Results:** The participatory advisory board generated 4 film narratives from the in-depth interview transcripts. Major themes of HIV-stigma included enacted stigma from neighbors, school children, and caregivers. The in-depth interviews from community members (e.g. shop keepers, pastors, and teachers) emphasized enacted examples of HIV-stigma from community social systems, including public ridicule, shaming, and shunning for families and adolescents living with HIV. HIV-infected adolescents shared personal narratives of perceived HIV-stigma in school and college environments, and experiences of enacted stigma from caregivers and family members. Filming and producing the films was conducted in July 2015, followed by post-production editing. Using local Kenyan actors in partnership with Moi University, the collaborative team created four film narratives that showcase the experience of HIV-stigma from the perspective of HIV-infected adolescent main characters.
**Conclusions:** Using a context-focused methodology and community participatory approach, we developed four unique films showcasing the impact of HIV-stigma in western Kenya. With planned use in clinical, counseling, and community-based settings, these films could mitigate the impact of HIV-stigma and serve as tools to encourage dialogue and openness about HIV.

## TUPED373

### STIGMA IN THE AGE OF UNDETECTABILITY

L. Thorley[1], A. Hudson[2]
*[1]Family Planning Association and Public Health England, Stigma Index 2015, London, United Kingdom, [2]Family Planning Association, London, United Kingdom*
*Presenting author email: alastairh@fpa.org.uk*

**Background:** In the age of undetectability and wide usage of ART, the 2015 UK Stigma Index (UKSI2015) indicates that stigma - felt, anticipated, or enacted - remains a persist feature in the lives of almost half of people living with an HIV diagnosis. As a result, the quality of life for people who are living with HIV (PLWHIV) is negatively affected. This research, which is a continuation of the quantitative data formulated by the UKSI2015, aimed to ask why people who are living with HIV experience stigma in this way.
**Methods:** 35 semi-structured interviews were carried out with a representative sample of PLWHIV. Interviews were conducted either in person, viva skype or over the phone. The researcher who conducted these interviews is HIV+. It is her status that afforded her a common ground with interviewees. The methods employed in the analyses of the data were pre-determined themes and inductive analyses.
**Results:** This research found that felt, anticipated or enacted stigma is a complex process. It varies over time and is manifested in various situations, ranging from disclosing status to a new partner to discussing diagnosis with healthcare professionals and employees. It also demonstrated that there are differences in how heterosexual women and homosexual men accept and come to terms with their diagnosis. And also, how they experience stigma. Furthermore, it illustrated that people who are HIV+ are often unaware of what it means in terms of transmission when undetectable. Moreover, it demonstrates that of those who were interviewed, 90% experienced anticipated stigma, primarily because of a lack of knowledge within the wider population.
**Conclusions:** This research demonstrates that PLWHIV are still experiencing stigma, especially anticipated stigma. Furthermore, this research clearly shows that if the general public were aware of what it means to be living with HIV, then those who have HIV would experience less stigma. This research has the possibility to not only influence how voluntary organisations address the needs of those living with HIV, but also to inform national policy. It also proposes that there should be a unifying voice from the medical community when discussing what it means to be undetectable.

## TUPED374

### "TO DIE FROM PEOPLE'S GAZE": TRAJECTORIES OF WOMEN LIVING WITH HIV IN SWITZERLAND

V. Fargnoli
*University of Geneva, Sociology, Geneva, Switzerland*
*Presenting author email: vanessa.fargnoli@unige.ch*

**Background:** HIV-infected women are often ignored in debates about AIDS, especially in high income countries. Until now, studies of women remain rare, except those that focus on women considered at risk of transmitting HIV, such as sex workers. The over-visibility of some women, and the invisibility of others, demonstrates that the importance of HIV-infected woman has not yet been fully acknowledged. Furthermore, to be HIV-infected may have become medically commonplace in Switzerland, socially, it is still stigmatizing.
**Methods:** To examine the social experience of living with HIV and its daily management, 30 in-depth interviews with HIV-infected women (34 to 69 years old), diagnosed before 2000 were conducted in the French-speaking part of Switzerland from 2013 until 2015. Of the 30 participants, 27 were diagnosed before the arrival of antiretroviral therapies. Mainly infected through heterosexual relationships, all the interviewees shared the perception that they were not previously at risk for HIV infection because they did not belong to any at-risk groups.
**Results:** The cascade of "non-statuses" marking these women - not belonging to any targeted group, living in an in-between condition, with a virus labeled as "undetectable" - seems to increase their feelings of guilt and social illegitimacy, a phenomenon largely overlooked by the medical profession. The study reveals how it is still difficult and shameful for them to consider themselves as "HIV-infected" and therefore to disclose their situation to others. In addition, the study population indicates that stigmatization is not only associated with traditional modes of contamination (e.g. drug users, homosexuals). Although most of the women did not experience overt discrimination, the risk of rejection remains deeply embedded, revealing the presence of an important self-stigma effect.
**Conclusions:** This is the first qualitative study in Switzerland that sheds light on "other" women living with HIV. These findings demonstrate that favourable medical outcomes do not guarantee a better social life even for those who are not a priori stigmatized. Their HIV trajectory taught them how to transform an intolerable contamination into an acceptable story for themselves but also for others since several believed that they might not die from AIDS but rather from people's stigmatizing gaze.

## TUPED375

### DIMENSIONALITY OF DISCLOSURE OF HIV STATUS AMONG POSTPARTUM WOMEN ON ANTIRETROVIRAL THERAPY IN CAPE TOWN, SOUTH AFRICA

J. Hunter-Adams[1,2], A. Zerbe[3], T. Philips[2,4], Z. Rini[2], L. Myer[2,4], G. Petro[5], E. Abrams[3], K. Brittain[6]
*[1]University of Cape Town, Health Economics Unit, Cape Town, South Africa, [2]University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa, [3]Columbia University, ICAP, New York, United States, [4]University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [5]University of Cape Town & New Somerset Hospital, Department of Obstetrics & Gynaecology, Cape Town, South Africa, [6]Division of Epidemiology and Biostatistics & Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa*

**Background:** Disclosure of HIV status to sexual partners and others has been presented as a universally positive health behaviour and is widely encouraged by antiretroviral treatment (ART) programmes, providers and policies. However, disclosure is highly contextual and the positive effects of disclosure may be neither linear nor universal. We explored dimensions of disclosure among postpartum women on ART.

**Methods:** *As* part of the Maternal Child Health-Antiretroviral Therapy (MCH-ART) study, we conducted 47 in-depth interviews with postpartum women (median time postpartum, 9 months) who initiated ART during pregnancy at a public sector primary care clinic in Cape Town, South Africa. Primary elements of disclosure were coded and interpreted according to dominant themes and subthemes.
**Results:** The majority of women reported disclosing to at least one person, but only half reported disclosure to their partner. While disclosure to mothers, sisters, and friends was linked to emotional and other support, disclosure to partners was more commonly described in terms of duty or responsibility. HIV status was fundamentally private rather than public, and women expressed fear of attending clinics close to their homes because of the risk of public disclosure. Many women who did not disclose to partners were financially dependent on them, and in turn felt disclosure involved unnecessary risk. In contrast, a subset of participants reported taking medication in front of others without discussing their HIV status, which seemed to represent tacit disclosure.
**Conclusions:** Despite access to ART, stigma remained a feature in descriptions of disclosure, particularly in relation to partner disclosure. For women who tacitly disclosed, they either intentionally undermined the fear of being "known" as HIV positive, or else did not feel this stigma. The juxtaposition of tacit disclosure with ongoing stigma suggests an evolution of the epidemic in contexts of relatively good ART access, perhaps signalling normalisation and destigmatization. In this context, the strong promotion of disclosure by HIV-related services may unintentionally thwart attempts to continue the destigmatization of HIV status.

### CHANGES IN HIV-RELATED STIGMA IN EASTERN AFRICAN COMMUNITIES AFTER INTRODUCTION OF A LARGE HIV "TEST AND TREAT" INTERVENTION

C.S. Camlin[1,2], M. Getahun[1], K. Kadede[3], J. Kabami[4], E. Ssemmondo[5], T. Clark[6], M. Petersen[7], C.R. Cohen[1], E.A. Bukusi[8], M. Kamya[9], D. Havlir[6], E. Charlebois[2]
*[1]University of California, Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [2]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [3]Kenya Medical Research Institute, Kisumu, Kenya, [4]Infectious Diseases Research Collaboration, Mbarara, Uganda, [5]Infectious Diseases Research Collaboration, Mbale, Uganda, [6]University of California, HIV, ID and Global Medicine, San Francisco, United States, [7]University of California, Divisions of Biostatistics and Epidemiology, School of Public Health, Berkeley, United States, [8]Kenya Medical Research Institute, Nairobi, Kenya, [9]Makerere University College of Health Sciences and the Infectious Diseases Research Collaboration, Kampala, Uganda*
*Presenting author email: carol.camlin@ucsf.edu*

**Background:** The ART rollout is associated with reductions in HIV-related stigma, but pathways through which this occurs are poorly understood. Studies have focused on individual psychosocial measures, with less attention to understanding processes through which rapid diffusion of ART uptake affects changes in community-level attitudes and social norms.
**Methods:** We used longitudinal qualitative data to examine evidence for change in HIV-related stigma, and its pathways, in eight communities participating in an ongoing test-and-treat trial in Kenya and Uganda (SEARCH, NCT#01864603). SEARCH aimed to increase uptake and normalize HIV testing and care through community-led, multi-disease and patient-centered approaches. Baseline and year one data were collected using focus group discussions (n=8 groups) with participants at community health campaigns, and in-depth interviews with care providers (n=50), community leaders (n=32) and members (n=112). We analyzed data using grounded theoretical approaches and Atlas.ti software.
**Results:** A majority of those interviewed one year after SEARCH implementation reported feeling that HIV-related stigma had decreased in communities ("*people are not fearful anymore*"). Longitudinal analyses revealed improved attitudes towards people living with HIV/AIDS (PLWHA), reduced anticipated stigma and increasingly open discussions about HIV. However, there were reports of enacted stigma against some PLWHA following status disclosure, particularly women. Perceptions that stigma had reduced elicited new anxieties ("*now you cannot identify the infected*", and "*there is less fear for HIV... that causes us to worry, more people are going to get infected...*"). As testing saturated communities, many HIV-positive individuals were newly emboldened to disclose their status ("*these days you just take your drugs in the open..."*). As more individuals experienced benefits of ART they engaged in advocating for others to initiate ART. Those who did not feel safe to disclose were relieved that taking ART permitted them to more effectively conceal their status.
**Conclusions:** Social norms and attitudes related to HIV are rapidly changing in communities participating in a large test-and-treat trial. Benefits of ART embolden HIV-positive individuals to openly engage in care. These 'advocates' for ART are a key social influence on stigma reduction, and should be supported, as they are already playing a critical role in expanding ART uptake.

## TUPED377

### *"HOW CAN I TELL?"*: CONSEQUENCES OF HIV STATUS DISCLOSURE AMONG COUPLES IN EASTERN AFRICA IN THE CONTEXT OF AN ONGOING HIV 'TEST AND TREAT' TRIAL

I. Maeri[1], A. El Ayadi[2], M. Getahun[2], E. Charlebois[3], C. Akatukwasa[4], D. Tumwebaze[5], H. Itiakorit[5], L. Owino[1], D. Kwarisiima[6], E. Ssemmondo[5], N. Sang[1], J. Kabami[4], T. Clark[7], M. Petersen[8], C.R. Cohen[2], E.A. Bukusi[9], M. Kamya[10], D. Havlir[7], C.S. Camlin[2,3]
*[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]University of California, Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [3]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [4]Infectious Diseases Research Collaboration, Mbarara, Uganda, [5]Infectious Diseases Research Collaboration, Mbale, Uganda, [6]Makerere University Joint AIDS Program, Kampala, Uganda, [7]University of California, HIV, ID and Global Medicine, San Francisco, United States, [8]University of California, Divisions of Biostatistics and Epidemiology, School of Public Health, Berkeley, United States, [9]Kenya Medical Research Institute, Nairobi, Kenya, [10]Makerere University College of Health Sciences and the Infectious Diseases Research Collaboration, Kampala, Uganda*
*Presenting author email: irenemaeri@gmail.com*

**Background:** People living with HIV/AIDS (PLWHA) anticipate HIV-related stigma and fear disclosure to intimate partners. Yet, disclosure is critical to reducing HIV transmission and improving engagement in HIV care. This qualitative study characterized HIV disclosure experiences, consequences, and perceived norms among couples in communities participating in an HIV test-and-treat trial in Kenya and Uganda (SEARCH, NCT#01864603).
**Methods:** In-depth interviews were conducted with HIV care providers (n=50), leaders (n=32) and members (n=112) of eight communities. Data were analyzed data using grounded theoretical approaches and Atlas.ti software.
**Results:** Findings confirmed gender differences in the barriers to disclosure; while both men and women feared blame and accusation from intimate partners, women also feared violence and abandonment (*"I did not tell my husband because [what if] I tell him and he abandons me at the last moment when I am in labor?"*).
Positive consequences of disclosure included increased engagement in HIV care, and encouraging care-seeking and adherence in partners ("My husband keeps on reminding me 'have you taken those drugs?") Yet negative consequences occurred, including partnership dissolution, blame and accusation, and reports of violence ("*some men beat their wives just because of that [bringing HIV medications home]"*).
Among HIV-infected individuals in discordant relationships, men more often reported supportive spouses ("*we normally share [HIV risk reduction strategies] since I have been infected and she is HIV negative*"), than did women ("*my husband refused to use condoms and even threatened to marry another wife".*)
Care providers lent support for HIV-positive women who wanted to engage partners in testing but feared negative consequences: "*They engaged the two of us in a session and asked him if we could all test."*
**Conclusions:** Findings demonstrate differing disclosure experiences and support needs of women and men living with HIV in east Africa, with HIV-positive women in discordant couples particularly vulnerable to negative consequences of disclosure. Care providers are already playing an important role in facilitating disclosure for PLWHA; efforts to strengthen capacity in health systems for gender-sensitive clinician- or counselor-assisted disclosure should be accelerated within test-and-treat efforts.

### EXPERIENCES OF STIGMA AGAINST PARTICIPANTS IN A NETWORK INTERVENTION TO REDUCE HIV TRANSMISSION FROM RECENTLY INFECTED PEOPLE IN ATHENS, GREECE AND ODESSA, UKRAINE

L.D. Williams[1], S.R. Friedman[1], J. Schneider[2], E.-G. Kostaki[3], E. Morgan[4], M. Psichogyiou[5], D. Paraskevis[6], A. Hatzakis[6], E. Pavlitina[7], B. Skaathun[8], A. Korobchuk[9], S. Muth[10], G. Nikolopoulos[7,11], Transmission Reduction Intervention Project Collaboration Group
*[1]National Development and Research Institutes, Inc, Institute for Infectious Disease Research, New York, United States, [2]University of Chicago, Department of Medicine and Department of Health Studies, Chicago, United States, [3]University of Athens Medical School, Athens, Greece, [4]University of Chicago, Department of Public Health Sciences, Chicago, United States, [5]Laikon General Hospital, First Department of Internal Medicine, Athens, Greece, [6]University of Athens Medical School, National Retrovirus Reference Center, Athens, Greece, [7]National Development and Research Institutes, Inc, Athens, Greece, [8]University of Chicago Medical Center, Center for AIDS Elimination, Chicago, United States, [9]Alliance for Public Health, Transmission Reduction Intervention Project, Odessa, Ukraine, [10]Quintus-ential Solutions, Colorado Springs, United States, [11]Hellenic Centre for Disease Control and Prevention, Athens, Greece*
*Presenting author email: lwilliams@ndri.org*

**Background:** Interventions to prevent HIV transmission by working with HIV-infected people and their networks may provoke stigma against participants if their infection statuses are inferred or disclosed. We examine the extent to which participants in such an intervention experienced stigma during or after their participation in the program in two sites with large epidemics.

**Methods:** Participants and controls in an intervention targeting recently infected individuals ("recents") and their sexual and injection networks were interviewed about their experiences of stigma and discrimination in follow-up interviews six months after entering the study. This intervention recruited recents' network members, and distributed community alerts among networks and at venues where recents reported injecting and/or meeting sex partners. These alerts indicated the presence of recents in the network, educated about protection from transmission, and urged recipients to support recents. Stigma items were operationalized as experiences of negative, stigmatizing behaviors like nasty comments, threats/attacks, or exclusions from social gatherings (4 items, Cronbach's α =.643) and experiences of positive, helping behaviors from others who thought they were recently infected (3 items, α = .675). Responses were compared by intervention site, by sex, and by study arm. Fifty-seven percent of participants reported that they injected drugs.

**Results:**

| | Total (N = 610) | Athens (N = 283) | Odessa (N = 327) | Male (N = 466) | Female (N = 144) |
|---|---|---|---|---|---|
| Mean number of types of stigma experienced (0-4) | 0.18 (S.D. = 0.56) Min = 0; Max = 4 | 0.28 (S.D. = 0.75) Min. = 0; Max = 4 | 0.09 (S.D. = 0.28) Min. = 0; Max = 1 | 0.18 (S.D. = 0.55) Min. = 0; Max = 4 | 0.17 (S.D. = 0.62) Min. = 0; Max = 4 |
| Proportion of participants experiencing at least one stigmatizing event (out of 4) | 12.3% | 16.6% | 8.6% | 13.1% | 9.7% |
| Mean number of types of positive/ helping behaviors experienced (0-3) | 0.77 (S.D. = 1.00) Min = 0; Max = 3 | 0.41 (S.D. = 0.87) Min = 0; Max = 3) | 1.09 (S.D. = 1.00) Min = 0; Max = 3) | 0.71 (S.D. = 0.99) Min = 0; Max = 3 | 0.96 (S.D. = 1.02) Min = 0; Max = 3 |
| Proportion of participants experiencing at least one positive/ helping event (out of 3) | 39.3% | 20.8% | 55.4% | 36.3% | 49.3% |

*[Frequencies and Descriptive Statistics for Stigma and Positive/Helping Experiences among Particpants]*

Reports of stigma were relatively infrequent. Frequencies of positive experiences were higher. Mean number of types of stigma experienced was less than 0.3 for all groups. Odessa participants reported fewer stigma experiences (t=-4.1, p< .0005), and more helping experiences (t=8.9; p< .0005). Females reported more helping experiences (t=2.6; p=.01). Nine individuals (all in Athens) reported being threatened or attacked. Field investigations determined these incidents were not caused by the intervention. Recents and their networks did not differ from controls on frequency of negative stigma experiences.

**Conclusions:** This intervention does not appear to present an unduly high risk of experiencing stigma related to "recent" status. It did seem to elicit support from others. Differences between intervention sites should be further examined to determine how local conditions affect stigma.

## TUPED379

### COMMUNITY SAVING SCHEMES: A SUSTAINABLE EMPOWERMENT MECHANISM FOR PEOPLE LIVING WITH HIV IN MITYANA DISTRICT, UGANDA

S. Nganda
*National Forum of PLHA Networks in Uganda, Program Development and Advocacy, Kampala, Uganda*
*Presenting author email: nganda.nafophanu@yahoo.com*

**Background:** While access to microfinance services is still a challenge for many Ugandans, the barriers for PLHIV is compounded by stigma and discriminatory practices and requirements manifested in form like difficulty in securing loan guarantors, lack of collateral by orphans and widows, perceptions by MFI s that PLHIV have little time to live among other according to study conducted by NAFOPHANU, AMFIU and ACORD. To overcome this discrimination PLHIV formed community saving schemes to create their own basket of credit to loan amongst themselves

**Description:** This started out as a pilot by NAFOPHANU in Mityana district. 15 groups were identified, trained and supported to start income generating enterprises including animal or crop husbandry, stone quarrying, poultry and bricklaying as a revolving scheme. From the income, they invested into saving schemes to create a pool of credit. No collateral except one's social standing and trust plus at a very small interest to steadily expand the fund

**Lessons learned:**

1. 13 have successfully formed vibrant savings schemes. One group in Malangala village started with 20 members but currently comprises of 187 members
2. The programme has enabled communities to appreciate the potential of PLHIV. With almost half of the co-save group membership comprising HIV negative community members, there is reduced incidences of stigma and discrimination for PLHIV in public life.
3. Communities are alive to the potential they hold to raise credit amongst themselves to invest in their development. The meagre investments of groups have grown to between 7 and 15 million shillings credit funds to date.
4. The mechanism contributed to PLHIV resource base and many have been able to finance treatment options that are not freely available in the public health care centers

Microfinance institutions have now expressed interest to offer the saving groups and their individual members saving, investment and loan facilities; a reversal in their earlier stance

**Conclusions/Next steps:** Reducing the economic vulnerability of PLHIV is critical in breaking the stigma and discrimination. Improving financial standing of PLHIV is essential for positive living and dignity.

# STIGMA AND DISCRIMINATION IN SPECIFIC SETTINGS, INCLUDING FAMILY, COMMUNITY, WORK PLACE, EDUCATION AND HEALTHCARE SETTINGS

## TUPED380

### THE SOCIAL CONSTRUCTION OF HIV STIGMA AND SEXUAL HEALTH SEEKING BEHAVIOUR AMONG BLACK SUB-SAHARA AFRICAN (BSSA) COMMUNITIES IN THE ENGLISH CITY OF BIRMINGHAM

M. Nyashanu[1], L. Serrant[2], H. Paniagua[3]
*[1]University of Wolverhampton, Public Health and Wellbeing, Birmingham, United Kingdom, [2]University of Wolverhanpton, Faculty of Education, Health and Wellbeing, Wolverhampton, United Kingdom, [3]University of Wolverhampton, Education, Health and Wellbeing, Wolverhampton, United Kingdom*
*Presenting author email: m.nyashanu2@wlv.ac.uk*

**Background:** There is a lot of quantitative research information in the public domain on HIV and stigma including sexual health seeking behavior. This statistical information has shown that BSSA communities present late with HIV and sexual transmitted infections owing to HIV stigma (Drummond, 2008). Currently there is very limited published qualitative information on the factors influencing the social construction of HIV stigma and sexual health seeking behavior among BSSA communities.

**Methods:** This research focused on the BSSA communities in the English town of Birmingham. A qualitative methodology was used to identify and explore the key factors influencing the social construction of HIV stigma and sexual health seeking behavior among BSSA communities. Screaming silences provided the theoretical underpinning for this study which sits in some aspects of feminism, criticalist and ethnicities based approaches(Serrant, 2010).

**Results:** The findings from this study were reviewed in light of current sexual health policies and strategies to consider how sexual health professionals and services can best meet the health care needs of BSSA communities. The institution of marriage,

religion, HIV epidemiological statistics, politics and immigration, HIV as a sensitive subject, sexual health professionals and sexual orientation emerged as key features of the social scripts associated with the social construction of HIV stigma and sexual health seeking behaviour among BSSA communities.
**Conclusions:** The social construction of HIV stigma and sexual health seeking behavior is influenced by commonly shared and personal appraisal of socially determined relevant issues. This forms the bases in which sexual scripts are given meaning and HIV stigma is constructed alongside a socially accepted pattern of sexual health seeking behavior. This research study compliments the currently available pool of quantitative data linking issues of HIV stigma and ethnicities in the United Kingdom. The findings from this thesis reveal a wide range of critical issues to embark on further qualitative research in the area while providing a lead for British based perspectives on HIV stigma and black ethnic minority groups.

## TUPED381

### STIGMA AND DISCRIMINATION IN HIV TESTING SERVICES: EXPLORING EXPERIENCES OF YOUNG TRANSGENDER WOMEN AND MEN WHO HAVE SEX WITH MEN IN KINGSTON, JAMAICA

C. Logie[1], N. Jones[2], K. Levermore[2], N. Brien[3], N. Lee-Foon[3], S. Tepjan[4]
*[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]Jamaica AIDS Support for Life, Kingston, Jamaica, [3]University of Toronto, Toronto, Canada, [4]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, ON, Canada*
*Presenting author email: tunagus@gmail.com*

**Background:** Stigma and discrimination reduce access to HIV testing. Men who have sex with
men (MSM) and transgender women experience pervasive human rights violations in Jamaica. Young MSM in Jamaica have the highest HIV infection rates in the Caribbean. There is little information about HIV among transgender women in Jamaica, who are overrepresented in the Caribbean epidemic. HIV-related stigma is a reported barrier to HIV testing among Jamaica's general population, yet little is known of HIV testing among MSM and transgender women in Jamaica. We explored HIV testing experiences among MSM and transgender youth in Kingston, Jamaica.
**Methods:** We implemented a community-based research project in collaboration with HIV and
lesbian, gay, bisexual and transgender (LGBT) agencies and community groups in Kingston. We conducted in-depth individual semi-structured interviews with young (18-29 years old) MSM (n=20), transgender women (n=20), and key informants (n=13). We also held focus groups with young transgender women (n=8) and MSM (n=10). We conducted narrative thematic analysis to identify, analyze and report themes.
**Results:** Findings revealed HIV testing experiences included: confidentiality breaches; healthcare
provider mistreatment; and HIV-related stigma. Participants discussed how physical arrangements in clinics that segregated persons receiving an HIV test led to confidentiality breaches by community members. In LGBT-friendly clinics participants were concerned about negative consequences from other LGBT persons discovering they were getting an HIV test. Participants were fearful that healthcare providers would disclose their HIV test results and discriminate against them. At times healthcare providers openly mocked participants trying to access HIV testing, condoms and lubricant. Many participants hid their sexual orientation and gender identity from healthcare providers due to fears of stigma. Participants expressed fears of testing HIV-positive—this intersected with the stigma of HIV as a 'gay' illness. Facilitators to HIV testing included nonjudgmental healthcare providers and mobile testing sites (e.g. health bus).
**Conclusions:** Findings suggest the need for policy and practice changes in HIV testing clinics in
Jamaica. Restructuring physical clinical spaces and anti-discrimination training for healthcare providers are required. Interventions to challenge HIV-related stigma, homophobia and transphobia in healthcare settings can enhance access to the HIV prevention cascade among MSM and transgender youth in Jamaica.

## TUPED382

### THE LONG ROAD TO LIFE INSURANCE

C. Suter
*AIDS-Hilfe Schweiz / Swiss Aids Federation, Zurich, Switzerland*
*Presenting author email: caroline.suter@aids.ch*

**Background:** The conclusion of a life insurance policy can have various aims:
• Providing a measure of financial security for the partner/family if the insured passes away
• Economic help in old age
• Protection of mortgages
Who wishes to become self-employed or buy a house/apartment, has to meet certain financial conditions. The required capital can be partly obtained as a mortgage. Getting a mortgage usually requires to present a life insurance. Until recently, people living with HIV were completely excluded from life insurance in Switzerland and therefore mostly unable to realize their dream of becoming self-employed or buying an own home.
**Description:** In 2013 the re-insurance company SwissRe carried out a study about the insurability of HIV-positive people treated with antiretroviral therapy. It was a collaborative analysis of HIV cohort studies throughout Europe. The study concluded that over 50% of those who are HIV-positive may be eligible for life insurance. Most of those living with HIV have a virtually normal life expectancy if being treated with antiretroviral therapy. This means that it is no longer justified to exclude HIV-positive people from life insurance if certain conditions are met (high CD4-count, no co-infection with hepatitis, etc.). Referring to the SwissRe study, the Swiss Aids Federation contacted Switzerland's life insurers and confronted them with the study results.
**Lessons learned:** Although the re-insurer specified in its study the conditions under which a HIV-positive person can be insured, the insurers inquired did not agree to provide life insurance to people living with HIV, even if they complied with the conditions mentioned above. After the sobering feedback, the Swiss Aids Federation established a cooperation with an insurance broker. He clarifies with the clients if the conditions presented by SwissRe are met and submits the application along with a medical certificate to the insurance companies.
**Conclusions/Next steps:** By interposing an insurance broker, several insurers agreed to make a life insurance contract. In a next step, the insurance companies will be contacted again to detect whether they are going to change their negative attitude considering the fact that some insurance companies now agree to supply life insurance to people living with HIV.

## TUPED383

### DISCRIMINATION IN HEALTHCARE SETTINGS AGAINST PLHIV IN MYANMAR

T. Htoon, M.S. Tun, Myanmar Positive Group
*Myanmar Positive Group (National PLHIV Network), Programme, Yangon, Myanmar*
*Presenting author email: thanhtoon.utopia@gmail.com*

**Background:** Marginalized communities across Asia face myriad human rights violations due to stigma, discrimination and weak or egregious policy and legal frame works that violate or fail to protect their rights. Communities face widespread social stigma, legislative and policy restrictions, and punitive legal frameworks that result in rights violation, including discrimination at health care settings.
**Description:** To address and end discrimination against PLHIV and KP at healthcare setting in Asia, Myanmar Positive Group was selected as one of the CBOs from Myanmar to participate in Asia Catalyst's Regional Human Rights Training Program. The program included sub-grant for documenting rights violation against PLHIV at healthcare setting. MPG together with Aye Myanmar Association conducted 40 interviews in 5 provinces in Myanmar.
**Lessons learned:** Various forms of discrimination at health care settings were documented in Myanmar. PLHIV were denied services following disclosure and were asked to find other service providers. When services were provided, PLHIV faced differential treatments as a direct result of their HIV status. This included forced additional expenses, publicly humiliating treatment, practices that breach privacy and confidentiality such as segregated waiting areas and bed spaces. Furthermore, service providers were also found deliberately engaging in unnecessary disclosure of the HIV status of the patient without consent. Concerning findings also included practices of coercive sterilization of Women living with HIV seeking pregnancy related services. These negative experiences discouraged PLHIV to seek timely health services resulting into sub-standard physical health and poor psychological state including added financial burden.
**Conclusions/Next steps:** The evidence clearly demonstrates that PLHIV and key population are not able to enjoy rights to health and non-discrimination enshrined in the Constitution of Myanmar. Ministry of health must take steps to address this and ensure zero discrimination at health care centers against PLHIV. MPG is mobiliz-

ing communities to urge the Ministry of health to issue a directive to health service providers to provide appropriate ethical capacity building to staff at all levels on discrimination and rights to health of PLHIV in Myanmar.

## TUPED384

### PAYING FOR SECRECY: YOUNG PEOPLE LIVING WITH HIV'S STRUGGLE TO SECURE SEXUAL AND REPRODUCTIVE HEALTH SERVICES

A. Gibbs[1], M. Dunbar[2], G. Chapwanya[2], N. Willis[3], P. Gomo[1], T. Mutasa-Apollo[4], T. Crankshaw[1], D. Nhamo[5], L. Langhaug[6]
*[1]Health Economics and HIV/AIDS Research Division, Durban, South Africa, [2]Pangaea Global AIDS, Pangaea Zimbabwe AIDS, Harare, Zimbabwe, [3]AFRICAID, Harare, Zimbabwe, [4]Ministry of Health and Child Care, Harare, Zimbabwe, [5]Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe, [6]The Regional Psychosocial Support Initiative (REPSSI), Harare, Zimbabwe*
*Presenting author email: dnhamo@pangaeaglobal.org*

**Background:** Integrated HIV-care and treatment and sexual and reproductive health (SRH) services are a key priority as part of a holistic response to adolescent health. Research has tended to focus on supply-side service delivery issues (such as creating adolescent friendly services) at the expense of understanding how young people navigate their way through an integrated system. We explored experiences of young people living with HIV (YPLWH) accessing SRH services.
**Methods:** YPLWH (n=8) were trained as peer researchers to undertake qualitative interviews with their peers (aged 16-25) in Zimbabwe (n=24) and South Africa (n=24). There were equal numbers of young men and women. In Zimbabwe, participants were recruited from support groups of YPLWH; in South Africa, participants on treatment were recruited through clinics. Discussions focused on access to SRH information and services. English language transcripts were thematically analysed.
**Results:** Young people in both Zimbabwe and South Africa expressed reluctance to access SRH information and supplies through their normal HIV clinics. Participants placed high value on anonymity while seeking SRH services so as to avoid potential judgement by their regular HIV providers and other community members attending the same clinics where they accessed care, even if they had not experienced this previously. This was primarily in response to their desire to retain a positive relationship with their primary healthcare worker who supported their HIV treatment and care. They felt raising issues of sex and SRH could break this relationship. A number of participants described paying to ensure secrecy around SRH seeking behaviour manifested itself in two ways: 1) buying condoms as opposed to collecting them for free at a clinic and 2) seeking out SRH services, information and commodities at alternative clinics, even though this involved extra costs for transport and user fees.
**Conclusions:** YPLWH demonstrated high levels of agency in ensuring privacy and avoid incurring censorship and discrimination while seeking access SRH information and commodities. Values clarification training for HIV healthcare workers is recommended and alternative innovate models of SRH/HIV integration should be considered.

## TUPED385

### A GROUNDED THEORY STUDY OF HIV-RELATED STIGMA IN US-BASED HEALTHCARE INSTITUTIONS

M. Davtyan[1,2], C. Lu[1], L. Spencer[2], T. Frederick[2], B. Brown[3]
*[1]University of California Irvine, Department of Population Health & Disease Prevention, Program in Public Health, Irvine, United States, [2]University of Southern California, Keck School of Medicine, Pediatrics, Los Angeles, United States, [3]University of California Riverside School of Medicine, Center of Healthy Communities, Department of Social Medicine and Population Health, Riverside, United States*
*Presenting author email: mdavtyan@uci.edu*

**Background:** HIV-stigma is pervasive in US-based healthcare settings as well as abroad. People living with HIV (PLH) report stigmatization from healthcare providers. While various studies have assessed stigma from the perspectives of PLH, there is a significant dearth of scholarship on healthcare worker conceptualizations of stigma. The aim of this study, therefore, was to develop a substantive theory that explains how healthcare workers perceive stigma.
**Methods:** Grounded Theory (GT) methods were used in the conduct of this study. Twenty-seven (N=27) healthcare workers from two US-based medical institutions were engaged in in-depth semi-structured interviews about HIV-stigma. Participants were queried on origins, triggers, manifestations, and impacts of HIV-stigma. Theoretical sampling and saturation were used for recruitment and data collection. Data analysis included open, axial and selective coding, comparative methods, memo-writing, and diagramming. MAXQDA was used to analyze and organize the data.
**Results:** Participants expressed that negative historical depictions of HIV/AIDS and unequal provider-patient power dynamics were responsible for stigma and subsequently led to fears of contagion, high variability in medical education, and changes in institutional norms. Respondents also noted that initial portrayals of HIV as a "death sentence" narrowed the field of specialization (overspecialization), making it difficult for non-specialists to care for PLH. Manifestations of HIV-stigma were described as preventive measures that exceed recommended guidelines, care refusal, unnecessary referrals to HIV-specialists, and overall reduced contact with PLH. Two findings were particularly striking:
One, overspecialization of HIV management and contact reduction diminishes normalization of HIV and result into "unintended stigma".
Two, HIV-stigma not only impacts patients, but also leads to harmful outcomes for providers including work-related anxiety and noninvestment in patients with HIV. Study participants asserted the importance of health communication in provider-patient relationships, PLH-driven medical trainings, and patient empowerment.
**Conclusions:** The emergent theory revealed that healthcare workers perceive HIV-stigma as an injurious process that disrupts the development of therapeutic patient-provider relationships. Additionally, HIV-stigma directed from medical providers may be "unintended" due to field overspecialization and contact reduction with PLH. The current qualitative work may inform future research on HIV-stigma reduction strategies within healthcare settings.

## TUPED386

### COMMUNITY RESPONSE TO HIV-RELATED STIGMA AMONG HEALTHCARE PROVIDERS IN UKRAINE: ALL-UKRAINIAN NETWORK MODEL

D. Dmytriyev[1], O. Bryzhovata[1], O. Vynogradova[1], O. Gvozdetska[2]
*[1]All-Ukrainian Network of PLWH, Innovative Programs Unit, Kyiv, Ukraine, [2]All-Ukrainian Network of PLWH, Program Department, Kyiv, Ukraine*
*Presenting author email: o.vinogradova@network.org.ua*

**Background:** According to the survey «Index stigma of people living with HIV» (2013), conducted in more than 50 countries, PLWHA in Ukraine experience stigma and discrimination (S&D) from the health care professionals (HCP), which directly affects their adherence to treatment. To overcome S&D among HCP All-Ukrainian Network of PLWH implemented 4-component model in pilot healthcare facilities (HF), which includes HCP training to reduce stigma, implementing of PLWH friendly policies, legal support to S&D cases. Implementation of the model was accompanied by a study of its effectiveness. The objective of the study was: assess of HIV-related S&D among HCP and determines changes in the level of S&D after the intervention.
**Methods:** The study was conducted in 12 HFs. Method, standardized face-to-face interview with HCPs in their workplace. The study has quasi-experimental design, is conducted by a panel and has two waves - before the model implementation (2013) and after (2014). The first wave sample - 1324 respondents, the second - 1441.
**Results:** The first wave of the study showed rather low level of knowledge and high level of stigma. The results of the second wave showed positive changes as a result of the model implementation: the level of knowledge about HIV transmission changes from 54% to 64%. Level of stigma caused by fear of being infected changed from 24% to 9%. Although 89% of HCP believed that treating HIV+ patients and other patients should be the same, herewith 57% (28% - the second wave) believe that PLWH should be treated separately from others to protect the general population from infection and 22% (17% - the second wave) say that if the HCP is afraid of infection from the patient, he may refuse to treat him. The positive dynamic is observed in the practice of disclosure of HIV status of the client without his/her consent - from 56% to 40%.
**Conclusions:** The model introduced in pilot HF in 2014-2015, has shown its effectiveness in reducing S&D towards PLWH among MPs. In 2016 this model extended to additional 26 medical institutions in four regions of Ukraine.

## TUPED387

### ADDRESSING STIGMA AND DISCRIMINATION IN THE UNITED NATIONS WORKPLACE

X. Orellana[1], D.O. Maina[2]
*[1]UN Cares, Geneva, Switzerland, [2]UN Cares. United Nations, Johannesburg, South Africa*
*Presenting author email: maina@unfpa.org*

**Background:** UN Cares, the HIV workplace programme for the United Nations system, has for a decade provided communication, training and other services to enable this global workforce to address HIV, including HIV-related stigma.
In 2013 UN Cares conducted a survey assessing the readiness of UN Cares teams globally to address stigma and discrimination in the UN workplace on issues related to HIV.

While many respondents were supportive, others said they would not or were unsure if they would feel comfortable working alongside the following colleagues: transgender: 16.7%; bisexual: 15.5%; lesbian (female): 14.0%; gay (male): 12.5%; HIV-positive: 6.1%.
60% of respondents thought the UN system should better address the needs of UN staff who identify as being from one or more of the above population groups, as well as 92.4% who thought this for persons with disabilities, and 63.9% for persons with mental health conditions.
**Description:** Therefore, UN Cares developed in 2015 four learning modules together called UN for All, addressing human rights, LGBTI issues, disability and substance use in the UN workplace.
Each module relies on personal accounts of UN staff who are part of each of the population groups. Participants are exposed to concepts and the latest facts, personal accounts promote empathy, and the UN workplace is examined through existing policies including the Universal Declaration of Human Rights. Modules are dynamic, hands-on and interactive.
**Lessons learned:** In late 2015, UN Cares trained 211 UN staff in 93 countries from 29 UN organizations to facilitate these sessions with colleagues. On a scale of 1 to 5, aggregate feedback so far is: Core module, 4.43 and, LGBTI module, 4.48. One comment: "This was a real eye-opener for me. I took many things for granted and realized that I did not know even the terminologies (LGBTI)."
Even in contexts where discussing the rights of LGBTI persons is difficult, setting an organizational expectation of respect and inclusion, and referring to human rights agreements, can help.
**Conclusions/Next steps:** UN Cares will continue to implement UN for All across the organization and share lessons.

## TUPED388

### HEALTHCARE WORKER REFLECTIONS ON THE RELATIONSHIP BETWEEN HEALTH FACILITY SPACE AND HIV STIGMA IN 21 SOUTH AFRICAN AND ZAMBIAN FACILITIES: THE ELEPHANT IN THE ROOM OF HIV SERVICE DELIVERY?

V. Bond[1,2], S. Nomsenge[3], L. Viljoen[3], M. Simuyaba[1], H. Mathema[4,5], T. Mainga[1], A. Stangl[6], J. Hargreaves[7], J. Seeley[7], G. Hoddinott[4], HPTN 071 (PopART) Study Team
*[1]Zambart, Lusaka, Zambia, [2]LSHTM, Global Health and Development, London, United Kingdom, [3]Desmond Tutu TB Centre, Social Science, Cape Town, South Africa, [4]Desmond Tutu TB Centre, Cape Town, South Africa, [5]National Institute for Communicable Diseases, Johannesburg, South Africa, [6]ICRW, Washington D.C., United States, [7]LSHTM, London, United Kingdom*
*Presenting author email: gbond@zambart.org.zm*

**Background:** Accessing antiretroviral treatment (ART) on a routine basis can be accompanied by anticipated and/or experienced stigma linked to 'being seen' at the health facility. The relationship between health facility spaces and HIV stigma for people accessing HIV-related services, and the added paradox of healthcare workers often 'hiding' their own HIV status in these spaces, is 'the elephant in the room' of HIV service delivery.
**Methods:** Healthcare workers key to HIV services (ART delivery and HIV counselling and testing) were interviewed in 21 urban government health facilities in South Africa (9) and Zambia (12), August to December 2015. This included at least three healthcare workers per facility. Participants completed either a mapping exercise or an in-depth interview (IDI). Both activities documented healthcare workers' perceptions and experiences of 'how comfortable' people coming for HIV testing and PLWH 'feel' in different areas of the facility and awareness of policies/guidelines on infection control, patient rights, stigma reduction and HIV. 89 healthcare workers (39 facility workers and 50 lay workers - 21/89 PLWH) participated; 3/89 participated in both mapping and IDIs. Structured observations were also carried out.
**Results:** Participants found talking about stigma in 'their' facility hard. The mapping revealed a relatively consistent pattern of PLWH fearing to be seen at the TB corner and in the general waiting and pharmacy areas as opposed to feeling comfortable in the specialised HIV spaces. Items, like HIV testing slips, could be stigmatising. There was low awareness of policies/guidelines. Some health facilities had a separate ART system for healthcare workers LWH who were anxious about being identified, rarely disclosed to co-workers and identified 'self-stigma' as the strongest type of stigma.
**Conclusions:** Tailored interventions are needed for stigma related to health facility layout for everyone accessing HIV-related services, including healthcare workers living with HIV. Removing HIV identifiers (e.g. signs, coloured referral slips), putting policies/guidelines into practice, introducing integrated services, promoting all clinic spaces as 'HIV equal' and 'stigma free', 'self-stigma' reduction strategies and PLWH support group activities might mitigate stigma. Additional interventions for healthcare workers LWH - a 'key population' facing additional challenges accessing HIV services - urgently need careful consideration.

## TUPED389

### HEALTH CARE WORKER ATTITUDES AND BEHAVIOURS TOWARDS KEY POPULATIONS IN SOUTH AFRICA AND ZAMBIA: A CROSS-COUNTRY ANALYSIS WITHIN THE HPTN 071 (POPART) TRIAL

S. Krishnaratne[1], H. Mathema[2], A. Stangl[3], G. Hoddinott[4], V. Bond[5], J. Hargreaves[1]
*[1]London School of Hygiene and Tropical Medicine, Social and Environmental Health Research, London, United Kingdom, [2]Western Cape Department of Health, Cape Town, South Africa, [3]International Centre for Research on Women, Washington, United States, [4]Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Stellenbosch, South Africa, [5]London School of Hygiene and Tropical Medicine, Zambart, Lusaka, Zambia*
*Presenting author email: shari.krishnaratne@lshtm.ac.uk*

**Background:** HIV-related stigma within healthcare settings may act as a barrier to the uptake and delivery of HIV care, particularly among key populations (KP) such as female sex workers (FSW) and men who have sex with men (MSM). This work describes attitudes and behaviours towards KP among health workers (HW) involved in the delivery of a package of HIV prevention interventions aimed at reducing community level HIV incidence. The work is nested within the HPTN071(PopART) trial, conducted in 9 communities in South Africa (SA) and 12 in Zambia (Z).
**Methods:** Data were collected from all facility- and community-based HW working in study communities who consented to participation in a quantitative survey (N=1875). HW were asked to respond to the same 9 statements about their perspectives on three populations (young women who become pregnant before marriage, FSW, and MSM) using a 4-point Likert scale of strongly agree, agree, disagree, and strongly disagree. The statements pertain to community-level stigma, co-worker stigma, and personal attitudes. We calculated combined proportions of HW who agreed or strongly agreed with each statement for each KP, stratified by country.
**Results:** In both countries, HW agreed more with statements about community-level stigma than co-worker or personal stigma. The statement 'People sometimes talk badly about' each KP received the highest proportion of agreement across all statements (range across 3 KP, SA:81.1-91.5%; Z:89.1-94.4%). For the statement 'My co-workers sometimes talk badly about' each KP, agreement was much lower (range SA:12.4-14.4%; Z:21.0-23.3%). Agreement with the statement 'If I had a choice, I would prefer not to provide services to' each KP was lower still (range SA:9.3-10.2%; Z:4.4-10.5%). Overall, agreement with statements about attitudes towards young women who become pregnant before marriage was lower than for attitudes towards FSW and MSM. Agreement with all statements was generally higher in Zambia than South Africa.
**Conclusions:** Our analyses suggest that stigma towards KP may exist within health care settings in PopART study communities and that the level of stigma perceived by HW may be higher in Z than SA. Further analyses will investigate how stigmatizing attitudes towards KP might differ across types of HW, and across socio-demographic characteristics.

## TUPED390

### FLAG MY VOICE: PAIRING INFLUENTIAL LEADERS AND LGBT COMMUNITY MEMBERS TO ELIMINATE STIGMA AND DISCRIMINATION IN RURAL TOWNSHIPS OF MPUMALANGA

E.B. Mabasa[1], L. Bruns[2], P. Brouard[3], R. Mohlahlane[3]
*[1]ANOVA Health Institute, Empowerment BP, Johanesburg, South Africa, [2]University of California Los Ageles, Center for World Health, Los Angeles, United States, [3]University of Pretoria, Center for Sexualities Aids and Gender, Pretoria, South Africa*
*Presenting author email: mabasa@anovahealth.co.za*

**Background:** The South African National Strategic Plan (NSP) on HIV, TB and STIs (2012-2016) includes the promotion of human rights and justice, as both play a paramount role in ensuring equity in access to and uptake of services. However, high levels of stigma and discrimination directed at Lesbian Gay Bisexual and Transgender (LGBT) community members prevent the achievement of equity. Under the "Flag my Voice" programme we used a challenging yet innovative approach of supporting LGBT members to form partnerships with local influential leaders to give a voice to and bring about change in attitudes of stigma and discrimination in the Gert Sibande (GS) district communities.
**Description:** Ten local LGBT volunteers participated in prevention trainings and interactive programme design meetings. Participants were supported to approach influential public figures, such as police, taxi drivers and business owners, to work in pairs. Each pair developed a specific action plan using print media, radio and outreach activities, capitalizing on the influential positions of the public figures. These interventions resulted in: a) continued dialogue between LGBT and the community about LGBT rights; and b) the diffusion of positive behavior change. Results were documented using digital stories and presented during community feedback events, inspiring the expansion of the programme to include municipal departments, CBOs and NGOs in addressing similar issues.

**Lessons learned:** Availability, disinterest and self-stigmatization present real challenges when working with public figures. LGBT volunteers need adequate information and training to successfully mobilize potential partners. Strong religious and cultural beliefs continue to contribute to high stigma and discrimination; however, working with non-gay identified leaders in the pairs provided a strong new entry point into the community. Our use of digital stories to capture and promote positive messaging ensured continuity and helped sustain the programme with new working pairs.

**Conclusions/Next steps:** Community level stigma and discrimination prevention programmes can be effective when interventions have a hands-on approach, and are designed and implemented by local individuals, organizations and departments. Establishing new communication pathways through the formation of pairs encourages knowledge transfer, the development of relevant shared goals, and more integrated prevention interventions.

## TUPED391

### CLASSIFICATION OF REFUSALS TO PROVIDE CARE EXPERIENCED BY PLHIV: A PROPOSAL STEMMING FROM A COMMUNITY-BASED SITUATION TESTING SURVEY, APRIL 2015

C. Douay[1], D. Rojas Castro[1,2], S. Benayoun[1], A. Henry[1], F. Barbier[1], G. Quatremère[1], T. Brigand[1], F. Pilorgé[1], L. Pallot[1], A. Romby[3], L. Feldmann[4], A. Toullier[1]
*[1]AIDES, Pantin, France, [2]Groupe de Recherche en Psychologie Sociale (Social Psychology Research Group) (GRePS) EA 4163, Lyon, France, [3]Public Health Department, Aubervilliers, France, [4]General Practitioner Specialising in Gynaecology, Centre Municipal de santé Docteur Pesqué (Docteur Pesqué Municipal Health Centre), Aubervilliers, France*
*Presenting author email: cdouay@aides.org*

**Background:** Although provider refusal and discrimination in accessing dental and gynaecological care are frequently reported by persons living with HIV (PLHIV) in France and the rest of Europe, they are very poorly documented with official data.
French law provides for a concrete legal classification of the reasons for refusing to provide care only when such refusals are directed at low-income individuals (because of a specific health insurance coverage): outright refusals; discouragement strategies or disguised refusals (unusually long waits for an appointment, abusive or repeated referrals to a colleague, etc.); and discriminatory practices (a specific protocol, a breach of doctor-patient confidentiality, etc.). This classification was transposed to the context of PLHIV.
To document and classify possible differential treatments in accessing care between PLHIV and persons assumed to be HIV-negative in France, AIDES, a community based organisation for the fight against HIV and hepatitis, conducted a situation testing survey.

**Methods:** The situation testing survey which used a community-based research protocol, was carried out in April 2015 among 440 dental offices and 116 gynaecology offices randomly selected in 20 French cities.
The replies from each medical office to two medical appointment seekers with the same sociodemographic characteristics, differing only in their HIV serological status, were observed.

**Results:** Among the 440 dental offices that were contacted, there were 3.6% outright refusals to provide care, 30% disguised refusals to provide care, and 16.8% instances of discrimination attributable to HIV. For the gynaecology offices, the figures were, respectively, 1.7%, 4.3% and 17.2%.

**Conclusions:** There were refusals to provide care, both outright and disguised, and discrimination directed at PLHIV when they requested an appointment. The classification of reasons for refusing to provide social care is fully transposable and suited to HIV-phobes' refusals to provide care, which fall under the same illegal practices. This situation testing survey made it possible to test this classification in real-world situations for the first time in France to reveal violations of medical ethics. Its effectiveness proves that this classification should be extended and endowed with a genuine legal framework.

## TUPED392

### HIV-RELATED STIGMA AMONG SPANISH-SPEAKING LATINOS IN AN EMERGING IMMIGRANT RECEIVING CITY IN THE UNITED STATES

S. Dolwick-Grieb[1], H. Shah[2], A. Flores-Miller[3], C. Zelaya[4], K. Page[5]
*[1]Johns Hopkins School of Medicine, Center for Child and Community Health Research, Baltimore, United States, [2]Johns Hopkins School of Medicine, Baltimore, United States, [3]Baltimore City Health Department, Baltimore, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [5]Johns Hopkins School of Medicine, Division of Infectious Diseases, Baltimore, United States*
*Presenting author email: sgrieb1@jhmi.edu*

**Background:** Latinos infected with HIV in the United States (U.S.) present to health care services with more advanced disease than their non-Hispanic counterparts, with undocumented foreign-born men at highest risk for delayed diagnosis and presentation to care. HIV-related stigma has been associated with a reluctance to test for HIV among Latinos in the U.S. Despite the harmful impacts of community-wide stigma on HIV prevention and linkage to care efforts, there is limited data on the nature and degree of HIV-related stigma in urban Latino immigrant communities. Understanding and combating stigma in the community is crucial to improving HIV prevention and outcomes. Thus, this study assessed community HIV-related stigma within an emerging Latino immigrant receiving city.

**Methods:** We conducted a brief survey among a convenience sample of 312 Spanish-speaking Latinos. HIV-related stigma was assessed through 6 items selected to incorporate multiple stigma domains: fear of transmission and disease, anticipated stigma, association with shame, blame and judgment and support for discriminatory actions or policies against PLHA. Associations between stigma items, sociodemographic characteristics and HIV testing history were considered.

**Results:** We found a high prevalence of stigmatizing beliefs, particularly with regards to fear of infection due to an inaccurate understanding of HIV transmission and association with blame, shame and judgment about people infected with HIV. Gender, education and religiosity were significantly associated with stigmatizing HIV-related beliefs. For example, men were 3.4 times more likely to hold more than 3 stigmatizing beliefs than women, and were also twice as likely as women to report feeling hesitant to test for HIV for fear of people's reaction if the test is positive.

**Conclusions:** Our findings revealed several attitudes and beliefs that likely propagate HIV-related stigma in the Latino immigrant community. These findings can help inform future stigma interventions in this community. In particular, we were able to distinguish between drivers of stigma such as fear and moralistic attitudes, highlighting specific actionable items. Understanding community level HIV-related stigma is a first step to developing culturally sensitive interventions that address the needs of the growing Latino immigrant population in the U.S.

## TUPED393

### THE HUMAN RIGHTS AND HIV/AIDS PROGRAM: A COMMUNITY-BASED PROGRAM TO PROTECT THE RIGHTS OF PEOPLE LIVING WITH HIV (PLHIV)

L. Liz
*COCQ SIDA, Programme Droits, Montréal, Canada*
*Presenting author email: liz.lacharpagne@cocqsida.com*

**Background:** There is a public health paradigm under which respect for human rights is a key component of HIV prevention strategies. Indeed, it is now accepted that the non-respect of these rights contribute to spread the epidemic. Based on this, COCQ-SIDA (Quebec-wide coalition of organizations working on HIV/AIDS) implanted a Human Rights and HIV/AIDS Program (HRHAP) in 2005. The goal of this program is to promote and to protect the rights of PLHIV and support all COCQ-SIDA's members in their own strategies for promoting human rights.

**Methods:** The HRHAP performs legal monitoring of violations of PLHIV's rights and develop common policies and advocacy strategies. Moreover, an HIV information service (HIV Info Rights) was created in 2009 within the HRHAP. This service provides the opportunity for PHAs to receive free information and legal assistance on matters related to their serological status (discrimination, insurance, access to care, criminalization ...). Since its inception, more than 1,200 people have used HIV Info Rights: the number of users is increasing continuously, from 169 users in 2009/2010 to 230 in 2014/2015.

**Results:** The HRHAP has wrote a policy position on the criminalization of HIV exposure, representing the position of all COCQ-SIDA's members, and has participated in several cases at the Supreme Court of Canada. Also, with the support and involvement of its members, the HRHAP has carried out a community-based research project on access to dental care for PLHIV. This research allowed the HRHAP to inform dental care professionals about discrimination and access to care within the dental care services.

**Conclusions:** The HRHAP is conducting an advocacy project on discrimination in employment against PLHIV in particular due to the use of health questionnaires during recruitment process. In this context, the HRHAP coordinated the produc-

tion of a short film about this issue and conducted a survey on discrimination in employment. The HRHAP plans to make concrete recommendations to political and judicial actors to promote access and retention in employment for PLHIV. The HRHAP would also develop HIV Info Rights service and reach people who do not attend community-based organizations.

## TUPED394

### MY HEALTH, MY RIGHTS: SUCCESSFULLY CHANGING A HOSTILE LEGAL AND HIV ENVIRONMENT FOR TRANSGENDER WOMEN AND EFFEMINATE GAY MEN IN PUEBLA, AGUASCALIENTES AND MEXICO CITY METROPOLITAN AREA

J.J. Hernandez Chavez[1], O. Vasquez Chavez[2], J. Elizalde Peña[3], P.D.L.C. Suárez Hernandez[4], C. Cruz Camacho[5]
*[1]Colectivo Sol A.C, Ciudad de México, Mexico, [2]No Dejarse es Incluirse A.C, Puebla, Mexico, [3]Colectivo SerGay de Aguascalientes A.C, Aguascalientes, Mexico, [4]Centro de Apoyo a las Identidades Trans A.C, General Coordinator, Ciudad de México, Mexico, [5]Colectivo Sol A.C, Project Coordinator, Ciudad de México, Mexico*
*Presenting author email: kalocru@yahoo.com.mx*

**Background:** Mexico has a Human Rights (HR) legal framework which includes the HR of LGBTI persons, who continuously experience institutional violence, abuse and harassment which jeopardize their lives and hinder their access to security, justice and healthcare. Gender based violence and social homo/transphobia lead to high levels of hate crimes, hence the need to address such violence urgently.
**Description:** : "My health, my rights" (Mi Salud, Mis Derechos) identified, documented, analyzed and made visible the experiences of LGBTI populations regarding abuses and violations of their HR by health, security and justice authorities due to high prevalence of stigma and discrimination. The program documented how health, security and justice service providers abuse the HR of transgender women and "effeminate" gay men, especially when HIV is present, a factor that allows for further discrimination and violence. Participatory community assessments, community engagement strategies and practical participatory tools enabled beneficiaries to tailor public political actions to the social realities and lived experiences of the LGBTI communities. A data base identified the perpetrators as well as the norms, regulations, laws and international treaties being violated. Evidence-based advocacy and community mobilization helped changing harmful and abusive municipal regulations.
**Lessons learned:** Meaningful involvement of target populations in evidence-based advocacy interventions is a key element to ensure that legal changes in a hostile environment can take place. Establishing strategic alliances with key stakeholders facilitates entry to decision-making spaces. The program has reached 720 most at risk people MARP mostly Transgender women and effeminate gay men; documented 120 cases of HR violations; held 15 participatory community assessments, and 9 awareness sessions with police and justice staff and produced two practical guides to raise awareness among healthcare providers and police.
**Conclusions/Next steps:** Program outcomes indicate that promoting structural changes in close partnership with affected communities and key decision making allies, is an effective way to achieve structural changes in the environment, opens a path to include new partners already involved in other local initiatives, and contributes in reducing the risks of HIV linked with gender based violence and HR abuses..

## TUPED395

### STIGMA AND DISCRIMINATION EXPERIENCES IN HEALTH CARE SETTINGS MORE EVIDENT AMONG TRANSGENDER PEOPLE THAN MALES HAVING SEX WITH MALES (MSM) IN INDONESIA, MALAYSIA, PHILIPPINES AND TIMOR LESTE: KEY RESULTS

R.N. Cortes[1,2], L.B. Norella[3], M.C. Ignacio[4]
*[1]Philippine NGO Council on Population, Health and Welfare, Inc, ISEAN-Hivos Program, Pasay City, Philippines, [2]ISEAN Secretariat, ISEAN-Hivos Program, Jakarta, Indonesia, [3]Hivos Regional Office of South East Asia, ISEAN-Hivos Program, Jakarta, Indonesia, [4]Consultant, Manila, Philippines*

**Background:** To investigate the experience of stigma and discrimination (SAD) in health care settings (including HIV/AIDS and sexual and reproductive health services) among Males having Sex with Males (MSM) and Transgender (TG) persons in South East Asia, a four-country study conducted by the ISEAN-Hivos Regional Program (Global Fund HIV/AIDS Grant). It aims to provide information on the status of stigma and discrimination (SAD) among MSM and transgender persons using a questionnaire developed based on the forms of SAD as described in the Stigma and Discrimination Index Questionnaire.
**Methods:** The study's questionnaire described SAD in terms of the respondents' self-reported perception of: 1. Refusal of health care services, 2. Physical maltreatment, 3. Verbal maltreatment, and 4. Provision of health care service below standards. A total of 2,409 respondents, 30% (n=719) of whom are self-identifying male-to-female transgender persons, participated in this study. There were 264 transgender respondents from Indonesia, 204 in the Philippines, 174 in Malaysia, and 77 in Timor Leste.
**Results:** Overall, the results indicate that significantly more transgender respondents experienced SAD in health care settings compared to MSM. In terms of proportion, verbal maltreatment was the most commonly experienced (24.26%), followed by receiving a perceived low quality of health service (22.57%), being refused access to health care services (18.23%) and lastly, physical maltreatment (18.21%). Comparing across countries, there were proportionately more SAD experiences reported by transgender respondents in Timor Leste (41.06%), followed by Malaysia (32.67%), Philippines (7.47%) and Indonesia (2.0%).
**Conclusions:** The result of the SADS suggests that there is a wide variation across the four countries in terms of transgender persons experiencing stigma and discrimination. Verbal maltreatment is the topmost common form of SAD among transgender respondents. The study indicates that transgenders' personal experiences of SAD are more frequent than MSM. Also, about one third of the transgender respondents continue to experience SAD. Almost 60% of the transgender respondents, however, did nothing to address SAD. SAD still exists in health care settings, which needs support for more interventions to significantly decrease, if not totally eradicate SAD in its many forms.

## TUPED396

### HIV AND SEXUALITY RELATED MULTIPLE STIGMA AND LOSS OF SOCIAL SUPPORT EXPERIENCED BY HIJRA PERSONS IN MUMBAI, INDIA

A. Dange[1], S. Mengle Rawat[2], S. Banik[3], A. Shrivastav[1], D. Baruah[1], B. Horton[4], V. Anand[5]
*[1]The Humsafar Trust, Research, Mumbai, India, [2]The Humsafar Trust, Research and Advocacy, Mumbai, India, [3]Baldwin Wallace University, Department of Public Health and Prevention Sciences, Cleveland, United States, [4]Brown University, Anthropology, Providence, United States, [5]The Humsafar Trust, CEO, Mumbai, India*
*Presenting author email: alpana_ani@yahoo.com*

**Background:** In India, the marginalized subgroup of transgender, referred as Hijras constitute a high-risk group with 8.8% HIV prevalence. HIV related stigma is multifold when the person is also a Hijra person. A study, SHAKTI, funded by ICMR and NIH, focused on the aspects of stigma of HIV and sexuality among Hijra persons in Mumbai.
**Description:** A qualitative research study was undertaken to explore the multiple stigma related issues among Hijra communities. Data from Hijra persons was collected through 6 in-depth interviews and 7 FGDs covering a total of 50 Hijra persons.
**Lessons learned:** Hijra persons especially those in commercial sex were vulnerable to HIV, faced multiple stigma of sexuality, gender non-conformity, sex work and HIV in health care settings. HCPs in particular were trans phobic and were less knowledgeable about sociocultural aspects and health issues faced by Hijra persons which resulted in lack of competent and satisfactory health care services to Hijra persons. Hijra person reported negative attitudes from doctors and from nurses and ward boys. The attitude of these health care providers changed particularly upon learning HIV status of the Hijra persons. The negative attitudes from support staff accompanied by neglect and dissatisfactory treatment from providers at the public hospitals and ART centers resulted in Hijra persons postponing opportunistic infections' treatment and routine health check-ups. HIV status also led to ostracization by `Gurus' and loss of livelihood on account of outing of their HIV positive status to peers and potential clients.
**Conclusions/Next steps:** Hijra persons fall through the HIV care continuum due to the institutional and social factors. In order to retain Hijra persons in the HIV care, there is a need to develop intervention at two levels. Firstly, at the institutional level, there is an urgent need to implement evidence-based trainings among health care providers to promote understanding in terms of sex, gender, sexuality and health care challenges faced by Hijra. Secondly at the community level, there is a need to work with Hijra `Gurus' about `positive living' so that loss of social support is minimized for the HIV positive Hijra persons and retain them in HIV care continuum.

### STIGMA AND DISCRIMINATION FACED BY PEOPLE LIVING WITH HIV/AIDS AT HEALTH CARE SETTINGS

N. Goel[1], R. Rana[1], S. Mondal[2], R. Pathak[1], P. Joshi[1]
*[1]NACO, Delhi, India, [2]FHI 360, Delhi, India*
*Presenting author email: drngoel@yahoo.com*

**Background:** The People Living with HIV (PLHIV) faces stigma &discrimination at workplace, school settings and healthcare settings. This study aims to further recognize the underlying roots of stigma and discrimination associated with PLHIV in health care settings in India and factors that may facilitate promotion of more equitable attitudes and actions to support them.
**Methods:** The study was conducted in 17 districts covering 6 states of India. A total of 1,260 health care providers (HCPs) were selected for the study. The target group for the study was HCPs— Primary Group (medical staff) and Secondary Group (non-medical staff). Interviews with 635 doctors, 266 medical students, and 358 non-medical HCPs were conducted during the month of July 2014
**Results:** The study reveals that more than 50% of HCPs had incorrect knowledge of transmission through blood splashes to eyes or mouth. More than 75% of all HCPs believed sputum was a transmitter of HIV. Apart from incorrect knowledge, misconceptions such as the possibility of HIV transmission through touch, sharing clothes or utensils, mosquito bites, and breath were prevalent among HCPs. The medical staff reported taking extra precautions such as double gloves (77%), PEP (68%), boots (67%), vaccines (39%), and complete avoidance of the patient (6%) while dealing with an HIV-positive patient. Discriminatory practices were also found as 53% of medical staff reported that invasive procedures on patients from high-risk groups (sex workers, poor, etc.) were postponed until their serostatus was confirmed.
**Conclusions:** The discriminatory comes in form of segregation of PLHIV from other patients, labelling of beds, delay in treatment, breach of confidentiality, withholding HIV test results from patients, disclosure without consent, mandatory HIV-testing before invasive procedures, and providing insufficient or inadequate counseling. Gaps in knowledge, lack of training and policies, fear of contagion, and self-identified inefficiencies of doctors to treat PLHIV, contributed to an environment of stigma and discrimination toward PLHIV within health facilities. Need for an intervention targeting medical staff members addressing knowledge gaps, stigmatizing attitudes, and discriminatory practices within the health facilities have been identified by the study findings.

## TUPED398

### ADVANCING LABOUR RIGHTS OF PERSONS LIVING WITH HIV IN ARGENTINA

M.P. Renz, R. Cavallo, L. Lenzi, M.C. Trejo, I. Maglio, M. Lucas Gomez, K. Frieder, L. Cahn
*Fundación Huesped, Ciudad Autonoma de Buenos Aires, Argentina*

**Background:** Fundación Huésped (FH) observed a high percentage of complaints about employment regarding stages of applications and employer-employee relations at the moment when the person's HIV status becomes known. Our principal focus concerns discrimination in recruitment, and following hiring, due to HIV testing and regular medical exams.
This discriminatory attitudes continue to exclude a high number of HIV-positive individuals from the workforce.
**Description:** In the last 12 years, Argentina continues reaching toward employment rights as fundamental human rights. Via policy, incorporation of international criteria through our courts and the development of political agreements, the concept of the worker being subject to fundamental human rights has developed. Still, FH has daily pointed out discriminatory labour practices which are believed to be protected by legal dilemmas, and continue to prevent equal access and opportunity in employment.
**Lessons learned:** As a result of the advocacy of FH, in May of 2015, Argentina's Ministry of Labour issued Resolution 270 allowing the reporting of laboratory studies seeking the HIV status of job applicants. Thus, it stops the previous ¨limitless power of choice¨ by an employer, instead preserving human rights to dignity and equal treatment of applicants.
This resolution creates a force of law stating this is the "most favorable to the worker¨ and it enhances the scope of anti-discrimination rules in force, in Argentina, extending their application not only to the workplace but also to the pre-contractual period. To help properly apply these rules, FH is in a committee with community organizations and various government sectors. Difficulties faced in the implementation, dissemination and compliance with the resolution demonstrate the importance of this ongoing dialogue.
**Conclusions/Next steps:** Currently, Persons Living with HIV (PLWHIV) have no limits in their work goals, and can apply to any job of their choice for which they possess the required skills and technical capabilities. Living with HIV is no impediment to career development, it does not mean a greater cost to the employer, nor does it jeopardize the health of other employees. Therefore, FH continues to strive to break down all barriers that prevent PLWHIV access to work, and protection of effective implementation of Resolution 270/2015.

## TUPED399

### HIV-RELATED STIGMA AND DISCRIMINATION IN HEALTHCARE: FINDINGS FROM THE STIGMASURVEYUK 2015

Paterson[6], I. Reeves[7], M. Ross[8], L. Sharp[6], W. Sseruma[3], L. Thorley[9], G. Valiotis[10], A. Wolton[8], A. Hudson[1], V. Delpech[4]
*[1]Family Planning Association, London, United Kingdom, [2]Chelsea and Westminster Hospital, London, United Kingdom, [3]StigmaIndexUK - 2015, London, United Kingdom, [4]Public Health England, London, United Kingdom, [5]Terrence Higgins Trust, London, United Kingdom, [6]Glasgow University, Glasgow, United Kingdom, [7]Homerton University Hospital, London, United Kingdom, [8]Clinic Q, London, United Kingdom, [9]StigmaIndexUK, London, United Kingdom, [10]HIV Scotland, Glasgow, United Kingdom*
*Presenting author email: whitney.jennings@phe.gov.uk*

**Background:** Stigma and discrimination remain important barriers to HIV prevention and care. We examine the association between experiences of HIV discrimination in healthcare with worry about and avoidance of care.
**Methods:** STIGMASurveyUK 2015 is a community led project. Participants reported their experiences at a range of health care settings in the previous 12 months in an online anonymous survey. A 'discrimination' composite was based on the sum of scores of five questions regarding: being treated differently to other patients, refused treatment, given the last appointment of the day not by choice, and experiencing negative comments about people living with HIV or excess attention to barrier protection by healthcare workers. Descriptive, univariate and multivariate analyses were performed.
**Results:** 1528 participants (97%) completed the healthcare section. Mean age was 44 years (range 18 - 83 years). 1152 (76%) were male (948 [82%] identified as men who have sex with men) and 344 (23%) female (322 [93%] identified as heterosexual). 555 (36%) identified as Black, Asian or minority ethnic.
41% of participants (628) reported experiencing discriminatory treatment in a healthcare setting; 46% (147) of Black African or Caribbean participants reported discrimination compared to 41% (385/699) of white British ($p< 0.001$); and 18/32 (56%) trans compared to 41% of other participants ($p=0.034$).
Overall 60% (910) reported worrying about being treated differently to other patients and 29% (439) reported avoiding healthcare when required.
Of the 628 participants who experienced discriminatory treatment, 89% and 54% (n=628) reported worrying about being treated differently and avoiding care respectively. These figures were significantly higher compared to the 766 participants who reported no discrimination (27% and 10% respectively; $p< 0.001$ for both).
Experience of discrimination in healthcare was strongly associated with both worry about discriminatory treatment (aOR 14.25, *CI10.10, 20.09*) and avoidance of care when required (aOR 8.70, *CI6.27, 12.07*) after adjustment for demographics, diagnosed depression, time of diagnosis, disability, injecting drug use, self-image and resilience.
**Conclusions:** Experiences of discriminatory treatment in healthcare settings are strongly and independently associated with worry about care and avoiding seeking care when required. Sensitivity training targeted at healthcare workers to reduce discriminatory treatment of HIV-positive patients is required.

## TUPED400

### MEASURING STIGMA AND DISCRIMINATION AMONG PEOPLE LIVING WITH AND AFFECTED BY HIV IN CENTRAL UGANDA

S. Kentutsi
*National Forum of People Living with HIV Networks in Uganda, Kampala, Uganda*
*Presenting author email: skent41@nafophanu.org*

**Background:** Stigma and discrimination related to HIV&AIDS remain a barrier to access and utilization of services. In 2013, Uganda conducted her first ever PLHIV stigma index survey and key to note was to apply the tool to the regions to determine specific stigma levels. This has provided evidence that is used as an advocacy tool for effecting changes in the HIV&AIDS response in the region.
**Methods:** A standard structured cross-sectional survey design provided by GNP+, ICW, IPPF and UNAIDS was adopted for this survey. Specific methodological steps were derived from the accompanying PLHIV Stigma Index User Guide. The sample

was 2018 (1380 female, 638 males) PLHIV and affected persons. Ten districts from Central Uganda were represented. Data collection was completed in January 2015 by PLHIV.

**Results:**

§ Internal stigma manifests more than external stigma (53.7% versus 46.3%), more among women than men (60% versus 40%) and is highest in age group of 30-39 years. Thirty percent (30%) of PLHIV had low self-esteem and blamed themselves for being affected by HIV. However, stigma reduces with number of years someone lives with HIV

§ Stigma manifested more among PLHIV than those affected at 57.7% and 27% respectively

§ External stigma manifested itself largely through gossip (47.7%), verbal abuse (30%) and physical threats (14%). Exclusions from education and health services was minimal but quite high for those refused employment due to HIV status

§ Because of stigma, 40% had decided not to have children, 24% not to have sex, 21% not to get married and 10% not to attend social gatherings

§ Understanding of policies and laws stood at 63% but fewer people (38% rural, 55% urban) had ever discussed the contents contained in the documents. When rights were violated, only 39% had confronted or educated someone about it.

§ HIV testing was done largely on a voluntary basis and had disclosed status to health workers (85.5), family members (68%), social workers (64%).

**Conclusions:** The continuum of stigma has changed from wide spread social exclusion to internalized feelings and fears. Stigma reduction interventions should be premised on individual than the general community.

## TUPED401

### HIV-RELATED STIGMA WITHIN GP PRACTICES IN THE UK: FINDINGS FROM THE STIGMASURVEYUK 2015

I. Lut[1], W. Crenna-Jennings[1], D. Asboe[2], L. Benton[3], M. Hibbert[4], J. Jefferies[3], P. Kirwan[4], C. Kunda[3], R. Mbewe[3], S. Morris[3], J. Morton[5], M. Nelson[2], S. Okala[4], H. Paterson[6], I. Reeves[7], M. Ross[8], L. Sharp[6], W. Sseruma[3], L. Thorley[3], G. Valiotis[9], A. Wolton[8], A. Hudson[1], V. Delpech[4]

*[1]Family Planning Association, London, United Kingdom, [2]Chelsea and Westminster Hospital, London, United Kingdom, [3]StigmaIndexUK - 2015, London, United Kingdom, [4]Public Health England, London, United Kingdom, [5]Terrence Higgins Trust, London, United Kingdom, [6]Glasgow University, Glasgow, United Kingdom, [7]Homerton University Hospital, London, United Kingdom, [8]Clinic Q, London, United Kingdom, [9]HIV Scotland, Glasgow, United Kingdom*

*Presenting author email: irilut@gmail.com*

**Background:** The STIGMASurveyUK aims to identify how people living with HIV in the UK experience HIV-related stigma and discrimination in varied settings. We report on the experiences of people living with HIV within healthcare environments.

**Methods:** The STIGMASurveyUK was developed by people living with HIV and community members, in collaboration with clinicians and researchers. Adults living with HIV in the UK were recruited to complete an online survey from December 2014 to April 2015. Responses were anonymized, stored securely and analysed with community engagement.

**Results:** 1528 (97%) of participants completed the healthcare section. Mean age was 44 years (range 1883 years). 1152 (76%) were male (948 [82%] identified as men who have sex with men (MSM)) and 344 (23%) female (322 [93%] identified as heterosexual). 2% identified as trans.

1393 (91%) of respondents reported their GP (primary care doctor) was aware of their status. 55% (883/1528) reported feeling a high level of control in disclosure at the GP, while 54% (828/1528) felt a high level of support during the disclosure process in this setting. Fewer Black African or Caribbean reported feeling supported 47% (150/319) compared to White British participants 58% (552/948) ($p< 0.001$). A higher proportion of MSM reported feeling supported during disclosure 58.6% (558/952) compared to others 46.9% (270/576)($p< 0.001$).

In the past year, a third (498) of participants reported being worried or concerned about being treated differently to other patients at their GP practice and 14% reported avoiding care when required.

13% (195/1528) of respondents who had disclosed to their GP reported being treated differently to other patients at their practice. 19% (59/319) of Black African or Caribbean participants experienced different treatment compared to 10.2% (97/948) of White British participants ($p< 0.01$).

**Conclusions:** PLHIV in the UK reported experiences of stigma and discrimination in the general practice setting. This was particularly significant for persons from Black African or Caribbean communities Despite many participants reporting that GP clinic staff is aware of their status, only half report feeling in control and supported during disclosure. Educational tools for staff within GP practices are recommended to address HIV related stigma and discrimination in this setting.

## TUPED402

### HARD TIME AND SUCCESS: THOUGHTS ON XIAO FENG'S CASE AND PLHIV ACCESS TO MEDICAL SERVICE IN CHINA

S. Dong

*Ark of Love, Secretariat of CAP+, Beijing, China*

*Presenting author email: menglin2801@gmail.com*

**Background:** In China, PLHIV access to medical service can be a very difficult thing due to severe discrimination and stigma among the medical workers to PLHIV. It usually results that many small illnesses on PLHIV become big disease due to no timely treatment, particularly for those illnesses that need to have surgical operation, even if the law and government regulation had stipulated that no one can stop PLHIV access to medical service. The reasons behind it are 1 lack of correct HIV knowledge among medical workers; 2 few PLHIV dare to openly use legal stipulation to suit those hospitals and medical workers and protect their rights; 3 no supervision over the law and government regulation implementation; 4 PLHIV community did not loudly voice our demand out.

**Description:** In 2013, Xiao Feng, a 26-year-old PLHIV from Tianjin, openly suited a local hospital for rejecting him receiving surgical operation to treat his lung cancer with support from China Alliance of People Living with HIV(CAP+). After many difficulties, in 2015, the Tianjin Superior People Court openly made their judgement that XIao Feng win the case and received RMB70,000 as an compensation. During the whole process, CAP+ and Xiao Feng use many different ways include change illness file names to force the hospital to give him operation. They together experienced a long hard time and finally won the case and Xiao Feng received proper treatment finally.

**Lessons learned:** 1 properly use media to call the attention from the society;2 better negotiation skill to face the state owned hospital; 3 internet and new technical application in the whole process; 4 close cooperation between lawyers and community based groups; and 5 skillfully use the government policies, state regulations and laws in reality.

**Conclusions/Next steps:** We will summarize the successful experiences and provide future support to PLHIV. We will advocate our government to provide HIV related education to those medical workers in the state owned hospitals. We will draft education materials target to medical workers. We will unite our PLHIV community to go on advocate on the internet and in real life for our rights to access to medical service in this country.

## TUPED403

### KNOWLEDGE, ATTITUDES AND BEHAVIORS TOWARDS SELF STIGMA AND DISCRIMINATION ASSOCIATED WITH MSM IN KARACHI, PAKISTAN

A. William

*Parwaz Male Health Society, Monitoring and Evaluation, Karachi, Pakistan*

*Presenting author email: awais.william86@gmail.com*

**Background:** Being a young MSM and living in a close society like Pakistan is hard and excruciating painful. As an Islamic Republic, Pakistan does not acknowledge the existence of homosexuality. The impact of the self stigma and discrimination will have multiplier impact to this high risk marginalized MSM Community. Socially, they are alienated, and their sexual practice and behaviors are heavily restricted by the mainstream social and religious values. It is very hard to live with sexuality issue, where society keeps a blind eye to discuss sex education and other issues related to sexuality.

**Description:** Five focus group discussions (FGD's) with 5 participants each were carried out to identify the challenges faced by MSM's in Karachi, Pakistan. The participants were selected randomly through secondary quantitative data which was collected from service delivery reports of Volunteer Counseling and Testing-VCT of PMHS from May 25, 2012, till December 31, 2015. Ethical, verbal and written consent and other ethical considerations, as per PMHS's Institutional Manual were followed.

**Lessons learned:** All the participants of five focus groups share their personal experiences in detail about self stigma and discrimination towards them just because of their sexual orientation and preference. It also came into the light during the discussion that the harassment and sexual abuse they face and indifferent attitudes of family, friends, class mates and work colleagues towards them forced them towards self stigma. MSMs experience multiple health disparities including alcohol and drug use, partner violation and high risk sexual behavior leading to getting HIV infection.

**Conclusions/Next steps:** There is limited information on the impact of gay-related self stigma between MSM's and also within MSM communities in Karachi, Pakistan. In order to address self stigma and discriminations towards these MSMs and also to the larger population in this high risk marginalized segment of the society, there is urgent need for emphasized rights driven movements by educating the youth increasing their self esteem and social recognition through integrated approach that engaged, society, policy makers and MSM's themselves.

### ROLE OF PRIMARY MEDICAL CARE IN HIV RESPONSE IN UKRAINE: INVESTMENTS IN POST-GRADUATE EDUCATION OF FAMILY DOCTORS

O. Bryzhovata[1], V. Polyshchuk[2], O. Gvizdetska[3]
*[1]All-Ukrainian Network of People Living with HIV/AIDS, Program Department, Kyiv, Ukraine, [2]All-Ukrainian Network of PLWH, Innovation and Development Department, Kyiv, Ukraine, [3]All-Ukrainian Network of PLWH, Program, Kyiv, Ukraine*
*Presenting author email: v.polyshchuk@network.org.ua*

**Background:** The ways to achieve global strategies 90:90:90 in Ukraine, primarily involving professionals of specialized medical facilities (secondary health care). Herewith, little attention paid to the primary care medical assistance, which is provided for all citizens of Ukraine, including representatives of most-at-risk risk groups. Therefore more than 550 primary health care facilities are not involved into provision of medical care for HIV-positive people in Ukraine.
However, family doctors plays significant role in the cascade of services provided to PLWH. Family doctor has an opportunity to consult patients on the availability of HIV testing and interpretation of its results, as well as to refer patients for appropriate treatment and to monitor adherence to treatment and evaluating its results.
After analyzing the current work program cycles on postgraduate education of family doctors there was discovered that only 6 hours of practical lessons which cover issues of provision medical care to PLWH and MARPs in primary health care facilities. Pre-certification specialization courses program also doesn't include issues on HIV/AIDS.
**Description:** The curriculum of post-graduate training "Management of Patients with HIV/AIDS by Family Doctor" aimed to increase the level of knowledge and skills of family doctors on HIV/AIDS was developed and approved within USAID RESPECT project: "Reducing HIV-related Stigma and Discrimination for Most-at-Risk Populations in Health Care Facilities in Ukraine". 5 cycles of indicated TU with the participation of 111 family doctors were conducted in 2015.
**Lessons learned:** Results of studies show that the general level of knowledge of participants after training increased from 58% to 77%. In addition, as a result of the training, the level of communication and cooperation at regional level between family doctors, representatives of NGOs and specialized medical facilities increased.
**Conclusions/Next steps:** The number of patients referred to the HIV testing counseling centers and to the second level of health care services provision increased as a result of changing family doctors attitude to PLWH and willingness to share gained knowledge among other medical staff of HCFs.

## TUPED405

### HIV-RELATED STIGMA AND DISCRIMINATION IN RURAL COMMUNITIES IN KENYA: EXPERIENCES OF WOMEN LIVING WITH HIV AND COMMUNITY HEALTH VOLUNTEERS

W. Liambila[1], B. Mdawida[1], C. Warren[2], J. Aparna[2], L. Reichenbach[2]
*[1]Population Council, Nairobi, Kenya, [2]Population Council, Washington, DC, United States*
*Presenting author email: wliambila@popcouncil.org*

**Background:** PLHIV experience various forms of stigma and discrimination (S&D) both in their community and at health facilities. S&D has the potential to reduce demand for services and prevent PLHIV from accessing available care and treatment services. The purpose of this study is to assess the perception and experiences of HIV-related S&D among CHVs and PLHIV. This study is part of a larger study aimed at testing interventions to integrate family planning into HIV services at the community level.
**Methods:** This is a quasi-experimental before-and-after research design with a comparison site. Samia Sub -County of Busia County is the intervention site while Butula Sub-County is control site. Interventions will include a five-day training of CHVs in FP counselling using the community version of the balanced counseling strategy-plus job aids (BCS+), reducing HIV-related stigma and discrimination, and business skills to enable CHVs to run income-generating activities to sustain their operations. Baseline survey was undertaken in November and December 2015 and are reported here. The study population consisted of HIV positive women (N=1611) and CHVs (N=210).
**Results:** About 29% (N=1611) of all women living with HIV had experienced some form of stigma and discrimination. . Of those who experienced stigma and discrimination, a slightly higher proportion reported begin gossiped about in Samia (50%) compared to Butula (47.2%)(p>0.05). About 39% of respondents in Samia and 32% in Butula (P< 0.05) had been verbally assaulted due to their HIV status. CHVs also experience secondary stigma due to their support and care of PLHIV, 15% reported that family members or friends avoid them because they take care of PLHIV. In their work, however, CHVs also reported stigmatizing behaviors towards their PLHIV clients: about 15% avoid physical contact with PLHIV and 14% wear double gloves when touching patients with HIV.
**Conclusions:** Results from study show that there is a need to address S&D behaviours with CHVs. This is critical as we move towards relaying more on CHVs who are the frontline workers and who help to create linkages for PLHIVs to health care facilities.

## TUPED406

### THE LESS THAN GOOD QUALITY OF LIFE OF TRANSGENDER PEOPLE IN BRAZIL: RESULTS FROM THE MURIEL PROJECT

M.A. Veras[1], G. Saggesse[2], J.L. Gomez[2], S. Mcarthy[3], A. Cezaretto[4], M. Giovanetti[5], H. Hanada[5], D. Barros[2], R. Martins[5], J. Kraiczyk[6], L.F. Deus[2], C. Barros[7], Muriel Study Group
*[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Saúde Coletiva, São Paulo, Brazil, [2]Faculdade de Ciencias Médicas da Santa Casa de Sao Paulo, Sao Paulo, Brazil, [3]RAND Corporation, Los Angeles, United States, [4]Faculdade de Saúde Pública da Universidade de Sao Paulo, Sao Paulo, Brazil, [5]Centro de Referencia e Treinamento DST/AIDS, Sao Paulo, Brazil, [6]Programa Transcidadania da Secretaria Municipal de Direitos Humanos e Cidadania da Prefeitura de Sao Paulo, Sao Paulo, Brazil, [7]Universidade Catolica de Santos, Santos, Brazil*
*Presenting author email: maria.veras@gmail.com*

**Background:** Globally, studies increasingly show transgender people encounter alarming levels of discrimination and physical violence that may contribute to their disproportionately high rates of HIV/AIDS. Thus we examined experiences with violence and discrimination across domains - from their immediate family to experiences with educational, employment, health care, and even transportation sectors - to better understand the context of vulnerability in which transgender people operate in Sao Paulo, Brazil.
**Methods:** Between November 2014 and October 2015, 673 transgender individuals receiving care at either a health facility or social services completed an interview-administered survey. Socio-demographic characteristics, experiences with violence and/or discrimination, as well as self-reported HIV status among transgender people (FtM and MtF) were assessed in 7 municipalities of the State of São Paulo. Analysis of selected variables from the semi-structured survey is presented. Participants were asked to select one of the following categories to qualify their relationship with each domain: good, acceptable, troublesome, very bad and non-existent. Descriptive statistics are presented.
**Results:** Among the 673 trans people interviewed, 626 were MtF and 47 were FtM. 180 (26.87%) individuals reported being HIV-infected, 166 (24.78%) did not know their status and the remaining individuals did not disclosure their status. Nearly half (47.85%) described their relationship as "Good" with family and with their employers (44.87%), whereas approximately a third described their relationship as "Good" while using public transportation (33.28%), shopping (36.85%), and in religious settings (35.66%). Even fewer reflected positively on their experience with the educational system (21.99%), or the police (11.89%).
**Conclusions:** More than half of the transgender people interviewed in São Paulo do not have a good relationship engaging with basic institutions. In order to change the unacceptable living conditions faced by transgender people in Brazil, public policies and programs need to address specific institutions and work with a range of stakeholders to improve the daily experience of transgender individuals in Brazil.

## TUPED407

### PAIN AND NON-ADHERENCE TO ART ARE ASSOCIATED WITH PERCEIVED DISCRIMINATION BY HEALTH CARE PROVIDERS AMONG RACIAL MINORITY PERSONS WHO FORMERLY OR CURRENTLY USE DRUGS

A. Knowlton[1], M. Mitchell[1], C. Rushton[2], J. Keruly[3], T. Smith[3], N. Hutton[3], L. Wissow[1], M.C. Beach[3]
*[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]Johns Hopkins School of Nursing, Baltimore, United States, [3]Johns Hopkins School of Medicine, Baltimore, United States*
*Presenting author email: aknowlt1@jhu.edu*

**Background:** Racial/ethnic minorities, persons living with HIV (PLHIV), and persons who use drugs (PWUD) are vulnerable to major social stress, including discriminatory treatment by healthcare providers. Research suggests that social stress may contribute to physical and mental distress and disparities in HIV health outcomes. We sought to examine the role of pain on a vulnerable population's perceptions of discriminatory experiences from health care providers, and its associations with their adherence to antiretroviral therapy (ART).
**Methods:** Cross-sectional data from baseline of the AFFIRM Care study was used. The study recruited current or former drug using persons (n=276) attending an academic, urban US HIV clinic. Participants were primarily older (median age 53)

African Americans (97%), diagnosed with HIV a median of 20 years prior. Perceived discrimination from health care providers in the prior two years was defined as based on race/ethnicity, HIV, speech, and current or former drug use. Adherence was defined as excellent adherence versus less than excellent adherence or not taking ART for other than doctor-initiated reasons. Depressive symptoms were assessed by the CES-D 10.
**Results:** Three-fourths of participants reported pain in the prior 30 days that interfered with their normal activities, 36% reported recent heroin or cocaine use, and only 41% reported excellent adherence to ART. Logistic regression results indicated that perceived discrimination was independently associated with pain interference (AOR=1.47; 95% CI 1.08, 2.02) and non-adherence to ART (AOR=0.30; 95% CI 0.11, 0.77), as well as perception that their doctor would not believe them if they had serious pain (AOR=3.06; 95% CI 1.36, 6.89) and reports that their doctor had ever refused them pain medication they felt they needed (AOR=3.23; 95% CI 1.44, 7.27). Analysis adjusted for depressive symptoms and other potential confounders.
**Conclusions:** Perceived discrimination from healthcare providers was associated with pain and non-adherence to ART among drug using PLHIV. The results suggest ways in which perceived discriminatory experiences contribute to the population's disparities in healthcare quality and outcomes. Improved relationships between healthcare providers and drug using PLHIV, and enhanced access to safe, effective pain treatment, may help ameliorate PWUDs' disparities in pain and HIV health outcomes.

# REPRESENTATIONS OF STIGMA: SOCIAL ATTITUDES, MEDIA AND PUBLIC DEBATE

## TUPED408

### NO TOLERANCE FOR TOLERANCE: CONSTITUTIONAL CHALLENGE TO JAMAICAN TV STATIONS' REFUSAL TO AIR ADVERTISEMENT CALLING FOR LGBT RIGHTS

M. Tomlinson[1,2], A. Gifford[3], A. Gray[2], R. Elliott[1], D. Stollery[4]
*[1]Canadian HIV/AIDS Legal Network, Toronto, Canada, [2]Attorney-at-Law, Kingston, Jamaica, [3]Attorney-at-Law, QC, Kingston, Jamaica, [4]Barrister & Solicitor, Q.C, Edmonton, Canada*
*Presenting author email: relliott@aidslaw.ca*

**Background:** Stigma, discrimination and violence threaten the rights and health of LGBT Jamaicans, and undermine HIV interventions, contributing to HIV prevalence of 32.3% among Jamaican gay men/MSM (versus overall population prevalence of 1.8%). Jamaican human rights activists and AIDS-Free World produced "Love and Respect," a 30-second video advertisement calling for respect for human rights of LGBTI Jamaicans (http://tinyurl.com/JamaicaLoveRespect). Despite repeated requests, Jamaican TV stations refused to air it as a paid advertisement.
**Description:** Jamaican human rights advocate Maurice Tomlinson launched a court challenge, claiming the refusal amounts to an unjustifiable breach of his constitutional rights to freedom of expression and to disseminate ideas through any media, contrary to Jamaica's 2011 *Charter of Fundamental Rights and Freedoms*. He sought a court order that the TV stations air the ad in exchange for the standard fee. In November 2013, the court of first instance ruled against his claim of constitutional breach. With support from the Canadian HIV/AIDS Legal Network, Tomlinson appealed, alleging multiple errors in reasoning.
**Lessons learned:** The case is precedent-setting. It is the first case relating to LGBT rights before Jamaica's Court of Appeal. It is also the first case in Jamaica to address the issue of balancing constitutional rights between two private parties, rather than asserting constitutional rights against the state. Jamaica's 2011 Charter is among the minority of constitutions worldwide that provide for this "horizontal application" of constitutional rights. The TV stations argue their freedom of expression and right to property give them absolute discretion to refuse to air any material - and point to the criminalization of MSM in Jamaica, and concern about negative public reaction, in justifying their refusal. Tomlinson argues that media outlets' refusal to air material, which has the effect of infringing freedom of expression and the right to disseminate ideas through media, cannot be "arbitrary, discriminatory or otherwise unreasonable." Access to media is an important tool for human rights advocacy, particularly for marginalized, stigmatized communities.
**Conclusions/Next steps:** The appeal was heard in February 2016. Further appeals may be required. Media outreach accompanying the court case has generated ongoing coverage and commentary in Jamaican media.

# LEGAL PROTECTION OF PEOPLE LIVING WITH HIV AND KEY POPULATIONS

## TUPED409

### BEING STRATEGIC ABOUT STRATEGIC LITIGATION: USING STRATEGIC LITIGATION TO ADVANCE PUBLIC HEALTH OUTCOMES

T. Ezer[1], P. Patel[2]
*[1]Open Society Foundations, New York, United States, [2]Independent Consultant, Christchurch, New Zealand*
*Presenting author email: tamar.ezer@opensocietyfoundations.org*

**Background:** Strategic litigation can be a powerful advocacy tool to effectively address HIV as in addition to ensuring protective laws, policies and practices, it can also result in the empowerment of marginalized populations and lead to greater public awareness of relevant issues. Despite this, it remains an underutilized tool.
**Description:** To address this gap, we sought to identify why strategic litigation is underused; its limitations and risk; its benefits on health outcomes; and key lessons learned from almost a decade of experience in supporting litigation on HIV throughout the world.
The research was based on a comprehensive desk review of written and audio materials, including academic papers; publications by practitioners, funders, and international agencies; and legal filings and decisions. It was also based on key interviews with over two dozen funders and practitioners.
The research draws on a detailed discussion of six emblematic HIV-related cases. The cases were deliberately selected from a range of countries, including Namibia, Russia, Kenya and Canada and cover different HIV-related issues, such as access to opioid substitution therapy, coerced sterilization of HIV-positive women and access to HAART.
**Lessons learned:** Key lessons identified include:
• Strategic litigation should be part of a broader, long-term advocacy plan and involve partnership with other organizations and allies, including social movements. Further, organizations seeking to litigate on HIV should build relationships with a wide range of experts, including medical practitioners, epidemiologists, and health economists.
• Strategic litigation funders should provide multi-year funding to a range of organizations, including community-based organizations and advocacy organizations, and support complementary media activities.
• Organizations should draft an implementation strategy prior to litigating and reassess it as the litigation continues.
• Organizations should consider taking an incremental approach to litigation. For example, it may be strategic to challenge the police abuse of sex workers prior to challenging the criminalization of sex work.

**Conclusions/Next steps:** There is a need to both scale up the use of strategic litigation in the HIV response and to ensure it is used most strategically. To support this, the study findings will be widely disseminated to relevant funders, practitioners and organizations.

## TUPED410

### JUSTICE PROGRAMS FOR PUBLIC HEALTH: LESSONS AND GOOD PRACTICES

T. Ezer[1], E. Kamonyo[2], A. Maleche[3], R. Quinn[4], N. Burke-Shyne[5]
*[1]Open Society Foundations, New York, United States, [2]Open Society Initiative for Eastern Africa, Nairobi, Kenya, [3]KELIN, Nairobi, Kenya, [4]Independent Consultant, Montreal, Canada, [5]Open Society Foundations, London, United Kingdom*

**Background:** For many people living with HIV, people who use drugs, sex workers, and palliative care patients, rights violations are part of everyday existence, negatively impacting their health and well-being. Violations both impede access to health services, such as when police harassment prevents people who use drugs from accessing harm reduction, as well as to underlying determinants of health, such as safety or housing. Access to justice programs are critical in addressing these violations. However, in many countries, these programs are nonexistent, the link between rights and health is poorly understood, and there is little guidance on effective programming.
**Description:** To address this gap, we sought to identify good practices for access to justice programming in the context of HIV, drawing on almost a decade of experience in supporting this work in sub-Saharan Africa, Eastern Europe, and Central Asia. Our research was based on interviews and facilitated discussions with practitioners and funders, complemented by a review of materials from practitioners, academics, funders, and international agencies. Our findings were then vetted by over 40 expert reviewers before finalization in 2015 and launches in Kenya and Macedonia.
**Lessons learned:** Key lessons identified include:
· Lawyers need to meet communities "where they are at," working outside regular office hours, engaging in outreach, and addressing needs non-judgmentally.

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

· Trained paralegals drawn from the communities they serve are well-placed to provide rights education and "legal first aid," responding quickly to violations and addressing multiple needs.
· Integrating legal and health services leads to better access and more holistic care.
· With training and support, customary justice structures can play an important role in protecting rights and facilitating access to justice.
· Addressing a community's pressing, daily justice concerns lays critical groundwork for systemic change.
**Conclusions/Next steps:** The next step is to share good practices on access to justice programming in the context of HIV with practitioners, governments, and funders so that justice services become more responsive to the needs of marginalized groups and programs can be scaled up. We are also building the capacity of local implementers to document their work, identify systemic outcomes, and link this to advocacy and funding.

## TUPED411

### LEGAL ENVIRONMENT ASSESSMENTS: A TOOL TO GENERATE EVIDENCE FOR LAW, POLICY AND STRATEGY REVIEW AND REFORM IN AFRICA

A. Saha[1], C. Grant[2], M. Getahun[3], T. Sellers[3]
*[1]United Nations Development Programme, HIV, Health & Development (BPPS), Addis Ababa, Ethiopia, [2]UNDP Regional Centre for Africa Consultant, HIV Health & Development, Johannesburg, South Africa, [3]UNDP Regional Centre for Africa Addis Ababa, HIV, Health & Development, Addis Ababa, Ethiopia*
*Presenting author email: tilly.sellers@undp.org*

**Background:** The report '*Risks, Rights and Health*' of the Global Commission on HIV and the Law showed stigma, discrimination, punitive laws, police violence and lack of access to justice continue to fuel the HIV epidemic. It recommended conducting legal environment assessments (LEAs) as a method to generate evidence for changing unfavourable laws and policies pertaining to HIV. An LEA looks at HIV and human rights, and reviews legal, policy and regulatory frameworks in the context of HIV focussing on stigma and discrimination; women and gender; children and young people; criminal laws and key populations; and access to HIV treatment. In Africa, LEAs have been successfully used to generate evidence for law, regulation, policy and strategy review and reform and strengthen stakeholder capacities.
**Description:** With Norwegian and Swedish Government assistance, UNDP supported 10 African countries to conduct LEAs from 2013-2015. Guidance to conduct LEAs was developed and countries engaged with stakeholders (LGBTI, key populations, services providers, government ministries, the police, the judiciary and civil society), to build capacity and generate evidence on laws, policies, regulations and strategies pertaining to HIV, and to identify human rights barriers, challenges, and gaps. Evidence from the LEAs were used by governments to address gaps in their national policies and strategies, inform their global fund concept notes and engage in longer-term law and policy reform.
**Lessons learned:** Countries used evidence from the LEAs—for law revision to remove criminalisation of HIV transmission (DRC); to include lubricants in national drug list (DRC); to stop harassment of MSM (Malawi); to reform law and include protection for PLHIV, women and prisoners (Chad); to revise the law and remove criminalisation of HIV transmission (Mozambique); and to prioritise key population interventions in new national HIV plans (Nigeria). Evidence from LEAs were utilised to inform Global Fund new funding model concept notes (Cameroon & Kenya).
**Conclusions/Next steps:** Legal environment assessments generate evidence for countries to undertake law, policy and strategy reforms, build capacity of stakeholders and strengthen the voice of key and vulnerable populations to improve their access to rights-affirming HIV services.

## TUPED412

### PEER TO PEER LEARNING ON PREVENTING ANTI-HOMOSEXUALITY BILLS: THE DR CONGO AND BURKINA FASO CASE STUDY

G. Biock[1], B. Miligo[2], A. Saha[3], T. Sellers[4]
*[1]UNDP Country Office DR Congo, Programme Officer HIV and AIDS, Kinsasha, Congo, Democratic Republic of the, [2]UNDP Country Office Burkina Faso, National Adviser HIV and AIDS, Ouagadougou, Burkina Faso, [3]United Nations Development Programme, HIV, Health & Development (BPPS), Addis Ababa, Ethiopia, [4]UNDP Regional Service Centre for Africa, HIV, Health & Development, Addis Ababa, Ethiopia*
*Presenting author email: amitrajit.saha@undp.org*

**Background:** In February 2015, a political party in Burkina Faso introduced a draft Bill for discussion in the National Assembly, seeking to outlaw and 'repress' bestiality, paedophilia and 'same sex marriage'. News of this was shared between organisations working with key populations, lawyers, civil society organisations (CSOs) and UN agencies to discuss preventive measures. The groups sought support to draft a strategy to address/counter this challenge.
**Description:** An emergency meeting of all stakeholders to plan a course of action was organised. Actions planned and undertaken included quiet diplomacy, preparing counter-arguments, corresponding with key government officials including the President of the National Assembly and Minister of Justice, convening a meeting of key HIV/AIDS stakeholders to discuss next steps, and preventing media sensationalism. In response to this urgent need UNDP DR Congo, which had developed a document for Parliamentarians titled "ARGUMENTAIRE TECHNIQUE CONTRE LA CRIMINALISATION DE CERTAINES POPULATIONS CLES" shared the document promptly with stakeholders in Burkina Faso. Letters were sent with this argument to key stakeholders while interactions were held with select stakeholders to prevent furtherance of the agenda for the draft Bill, which was not taken up for discussion.
**Lessons learned:** A rigorous legal environment assessment in one country leads to significant learning and national capacity-building that can be used across nations if they share similar constitutional and judicial processes. In addition to technical expertise, the strong working group in DRC was the key institution in this case, and it convened at short notice to respond to the request from UNDP Burkina Faso for support. Collaboration between agencies, civil society and other stakeholders too was important to respond to similar emergencies.
**Conclusions/Next steps:** There is an urgent need to institutionalise preventing and addressing human rights violations through the establishment of a nation level working group or entity. Collaboration and peer to peer sharing of information and learning is important for strengthening South-South learning that can prevent adoption of harmful laws, policies and practices in the context of HIV.

## TUPED413

### HEALTH IMPACTS OF UNMET LEGAL NEEDS FOR LOW-INCOME WOMEN LIVING WITH HIV

R.B. Sears, A. Miyashita, A. Hasenbush
*Williams Institute, UCLA School of Law, Los Angeles, United States*
*Presenting author email: hasenbush@law.ucla.edu*

**Background:** The law can serve as a barrier or a facilitator to achieving health equity. In the United States, there is very little research examining the relationship between addressing individual rights under the law and possible health impacts of doing so. This is particularly true with regard to low-income women living with HIV. In a recent Ford-funded study, researchers collected surveys from primarily low income, cisgender and transgender women living with HIV to ask about unmet legal needs and self-reported health impacts stemming from those needs. Results regarding transgender women were previously released, however, results from cisgender women are new.
**Methods:** Researchers collected data from July through October, 2014, utilizing in-person computerized surveys administered throughout Los Angeles County, the second largest community of people living with HIV in the U.S. The final data set includes 387 total complete surveys of which 20% were completed in Spanish. Almost a third of all respondents (112) identified as cisgender and transgender women. Study procedures were approved by the UCLA Institutional Review Board. Data were analyzed using Stata v13.1. Inferential statistics were used to test differences between subgroups.
**Results:** Both cisgender (49%) and transgender women (44%) experienced legal problems with accessing health care and facing discrimination on the basis of HIV status (18% for cisgender and 24% for transgender women). While nearly half (44%) of transgender women reported being harassed, attacked with violence and/or subjected to another crime in the year prior to the survey, less than a quarter (24%) of cisgender women reported the same. While marginally significant (Pr=0.053), the study found that 77% of transgender women reported negative health impacts on physical well-being as a result of unmet needs compared to 56% of cisgender women.
**Conclusions:** All women reported experiencing unmet legal needs. These data illuminate commonalities and differences across women. While these differences may not always be statistically significant, data suggest that transgender women may experience more negative health impacts on physical well-being as a result of unmet legal needs. Results indicate the need for correlative studies to further illuminate the link between health and unmet legal needs.

## TUPED414

### STRENGTHENING THE HIV-RELATED LEGAL AND POLICY ENVIRONMENT FOR KEY POPULATIONS IN THE DEMOCRATIC REPUBLIC OF THE CONGO: A CASE STUDY

L. Ferguson[1], A. Saha[2], G. Biock[3], S. Tamundele[4], T. Sellers[2], S. Gruskin[1]
*[1]University of Southern California, Program on Global Health and Human Rights, Institute for Global Health, Los Angeles, United States, [2]United Nations Development Programme, HIV, Health and Development Team, Regional Service Centre for Africa, Addis Ababa, Ethiopia, [3]United Nations Development Programme, Kinshasa, Congo, Democratic Republic of the, [4]Ministry of Justice and Human Rights, Kinshasa, Congo, Democratic Republic of the*
*Presenting author email: laura.ferguson@med.usc.edu*

**Background:** Following the work of the Global Commission on HIV and the Law, there has been increased interest in the HIV-related legal and policy environment. Implemented by the United Nations Development Programme (UNDP), one such project seeks to use the Global Commission's recommendations to improve HIV-related legal and policy environments for key populations including LGBT populations and women and girls in 11 countries in sub-Saharan Africa including the Democratic Republic of the Congo (DRC).
**Description:** A critical mass of stakeholders, across different types of organizations including government, civil society organizations and United Nations agencies, each with access to different networks and champions have met regularly for the last few years and undertaken systematic and strategic advocacy, each playing to their respective strengths and collectively adopting multiple entry points for action to improve the HIV-related legal and policy environment. To maximize project learning, we did a desk-based document review and key informant interviews with project implementers and beneficiaries.
**Lessons learned:** Remarkable strides are being made to improve relevant HIV-related laws and policies in the DRC. Examples include 'creating an enabling legal and policy environment' as a key pillar of the National Strategic Plan on HIV; the addition of lubricant to the essential medicines list; and collective efforts to amend problematic provisions of the HIV law to protect people living with HIV.
These achievements derive largely from the unwavering commitment of key stakeholders, and relied on a robust evidence base as to why action was necessary. Findings and conclusions from the PLHIV Stigma Index and the UNDP-supported legal environment assessment were critical. Capacity building on HIV and the law (e.g. judges, health workers, parliamentarians) has been essential for raising awareness, ensuring appropriate service delivery, and creating an ever-increasing circle of advocates committed to positive change.
**Conclusions/Next steps:** The incremental gains in policies and related activities achieved to date should be appreciated and built upon as part of the process towards legal change. The fact that this work can take place to such positive effect in a conflict-affected country offers lessons to government, civil society and donors in other similarly situated countries.

## TUPED415

### LEGAL SERVICES: ESSENTIAL TO NATIONAL RESPONSES, YES, BUT WHAT ABOUT QUALITY AND COVERAGE?

D. Patterson[1], A.E.R. Abu El Ela[2], A. Brito[3], N. Riahi[4], O. Perez[5], A. Shehata[5], N. Meite[5], G. Zevi[5], M. Salah[6]
*[1]International Development Law Organization, Global Initiatives, The Hague, Netherlands, [2]Al-Shehab Foundation, Cairo, Egypt, [3]Letra S, Mexico, Mexico, [4]ATL MST SIDA Association, Tunis, Tunisia, [5]International Development Law Organization, Programs, Rome, Italy, [6]International Development Law Organization, Programs, Cairo, Egypt*
*Presenting author email: dpatterson@idlo.int*

**Background:** HIV-related discrimination is an obstacle to scaling up HIV prevention, care and treatment services in every country. The United Nations International Guidelines on HIV/AIDS and Human Rights identify legal services as a core State obligation. This program aims strengthen and expand HIV-related legal services, and to support law and policy reform.
**Description:** The current phase 2014-2016 took place in Latin America, Middle-East/North Africa, and West Africa. Technical and financial support was provided to non-governmental organizations in each country to provide quality legal services to PLHIV and other key affected populations - MSM, transgender, SW, prisoners and PWUD. NGO capacity was enhanced through regional networking and inter-regional consultations. Results include: building strong networks and sharing experiences; building awareness within communities by partnering with community-based organizations; expanding access to legal services; strengthening legal skills and knowledge, including in interactions with police and the criminal justice system; and influencing governmental and legal policy for sustainable outcomes, e.g. through strategic litigation and the inclusion of legal services in national plans. Independent evaluations found that the program has created cadres of informed attorneys, paralegals, judges, and community advocates who can now better utilize legal processes to protect human rights and improve health care access. Health care providers are now better informed about how to treat patients with respect and in accordance with human rights laws and policies. The program has supported the development of communication networks and information dissemination systems that are sustainable and which have led to increased community mobilization in response to HIV needs in the program countries.
**Lessons learned:** Community paralegals are needed to engage affected communities. Lawyers and paralegals need skills to work with police to reduce harms in hostile legal environments. Collaboration and partnerships between organizations and universities are needed to expand the provision of legal services and produce evidence for advocacy.
**Conclusions/Next steps:** To be sustainable, legal services must be integrated into national HIV plans and responses. State institutions providing counseling and legal assistance must be engaged. Tertiary legal education (including legal clinics) should aim to build HIV and health law and policy capacity.

## TUPED416

### LABOUR INSPECTION IN ENTERTAINMENT ESTABLISHMENTS PROTECT ENTERTAINMENT WORKERS IN CAMBODIA

C. Por[1], A. Torriente[2], R. Howard[3], R. Ameur[4], M. Licata[5], S. Mabhele[6]
*[1]International Labour Organization, Phnom Penh, Cambodia, [2]International Labour Organization, Geneva, Switzerland, [3]International Labour Organization, Bangkok, Thailand, [4]ILO, Pretoria, South Africa, [5]International Labour Organization (ILO), Geneva, Switzerland, [6]International Labour Organization, Pretoria, South Africa*
*Presenting author email: chuong@ilo.org*

**Background:** "Entertainment workers" in Cambodia include entertainers, massage staff, employees in nightlife establishments and beer promoters. Due to their working conditions, these workers are at high risk of HIV infection. Studies carried out by the ILO from 2005-2011 identified a number of specific vulnerabilities, including: work accidents; violence; sexual harassment; poor working conditions; forced alcohol consumption; and client refusals to use condoms.
**Description:** Based on the study findings, the ILO collaborated with the Cambodian Ministry of Labour and Vocational Training (MoLVT), trade unions, entertainment establishment owners and the Women's Network for Unity to develop a regulation on occupational safety and health for entertainment workers. These regulations mark an important "first" in protecting the basic rights of all entertainment workers, including their right to a safe and healthy workplace. The regulation, the first of its kind, was adopted by the MoLVT in August 2014 (*"Working Conditions, Occupational Safety and Health Rules of Entertainment Service Enterprises, Establishment and Companies" (Prakas 194), available at:.* The regulation extends labour protections available under Cambodian labour legislation to entertainment workers. IN 2015, to support implementation, the Government provided capacity building to labour inspectors and entertainment establishments.
To date, the MoLVT has trained more than 150 labour inspectors, and organized regular feedback meetings between the inspectors and entertainment establishments owners/workers to discuss progress and challenges encountered in implementation.
**Lessons learned:** A key factor in the successful implementation of the regulation was the establishment of an effective monitoring system to track progress in implementation.
Another important success factor is the on-going dialogue between the labour inspectors from the MoLVT and other key actors (including NGOs and civil society) to continuously promote improved working conditions and ensure occupational safety and health for all entertainment workers.
**Conclusions/Next steps:** The ILO will continue to provide technical support to promote the effective implementation of the regulations throughout all entertainment establishments in the country, with the aim of reducing HIV transmission among this key vulnerable group of workers.

## TUPED417

### INTEGRATION OF LEGAL AID SERVICES IN PALLIATIVE CARE (PC): EXPERIENCE OF USING COMMUNITY PARALEGALS TO PROTECT RIGHTS OF PALLIATIVE CARE PATIENTS

C.A. Nanyanzi
*Uganda Network on Ethics, Law and HIV, Legal, Kampala, Uganda*
*Presenting author email: nanyanzicathie@gmail.com*

**Background:** Most patients on palliative care experience human rights violations due to the fact that health workers dwell more on issues requiring medical attention which limits access to justice. Reports on stressed palliative care patients -majority with HIV; alarmed UGANET to intervene through training of Community paralegals

who worked with health facilities to raise awareness on human rights and linked many PC patients in need of legal aid to UGANET lawyers.
**Description:** 100 paralegals were identified from 5 regions of Uganda covering 10 districts. 10paralegals were trained from each district. They were trained in basic legal human rights knowledge and palliative care. UGANET handled the legal aspect and PCAU trained them in palliative care. 2paralegals were attached to the nearest health center providing palliative care services in each sub county.
Each paralegal raised awareness in the community about the available legal services from UGANET and the importance of palliative care to patients especially those who cannot travel to the health facilities. The palliative care team from the Hospices and Home care centers together with the legal officer link up with the paralegals to provide a holistic approach to palliative care patients.
**Lessons learned:** 100paralegals were capacitated with palliative care skills and empowered with basic legal knowledge; that supported 1530 (1001 F, 529 M) PC patients who had lost due to socio-cultural exclusion related to their health status. Out of these; 197 patients reported reduction in stress and depression after receiving free legal aid services from UGANET Paralegals and lawyers. 130 patients (98males and 32 females) reported improved adherence levels because their succession planning worries were sorted by community paralegals and lawyers through will making. Over all; treatment adherence has also improved and health workers attribute it better social welfare of PC patients.
**Conclusions/Next steps:** Holistic Palliative care as opposed to standalone medical palliative care remain critical in upholding the human value and dignity of patients. Clinical outreaches should go hand in hand with 'socio-legal' interventions through trained community paralegals to improve patient's quality of live. However; end of life care requires a lot of patience and commitment for impactful results.

## TUPED418

### HUMAN RIGHTS OF INTERNALLY DISPLACED PEOPLE (IDP) LIVING WITH HIV IN UKRAINE

N. Lukyanova[1], I. Yeleneva[2], T. Bondar[3]
*[1]UNDP, Kyiv, Ukraine, [2]LHSI, Kiev, Ukraine, [3]Institute of Social Science after Yaremenko, Kiev, Ukraine*

**Background:** According to official data of the Ukrainian CDC Center of the Ministry of Health of Ukraine, as of 01.01.2015, there were 137,390 people living with HIV (PLWHIV). In 2014, armed conflict in the Eastern Ukraine affected the region of approximately 5.2 million people including the Donetsk region which has high HIV and TB prevalence; 50% of the registered people living with HIV reside in 3 (out of 27) oblasts (Dnepropetrovsk, Donetsk, Odessa). The migration of PLHIV and key populations at higher risk of HIV to other regions of the country creates challenges, more cases of human right violations and an additional burden to the health systems of the host-regions (including ART distribution, prevention programmes and other).
**Description:** The focus of UNDP humanitarian response was to monitor the human rights violations of internally displace PLWHIV by using formative assessment, existing national and regional online online *google.doc* platform monitoring systems, national HIV hotline, and providing legal assistance to internally displace key population and PLWHIV via a small grant scheme for local NGOs from most affected areas.
**Lessons learned:** IDPs living with HIV experience difficulties and violation of their human rights (lack of proper medical services, and at the same time they face high stigmatization at the host communities). Most of the health institutions and medical specialists discriminate IDPs due to their HIV-positive status.The number of women IDPs living with HIV is much higher then men and they are more vulnerable to human right violations. Strong need for legal service of IDPs with HIV and local NGOs can provide legal support.
**Conclusions/Next steps:** The IDPs living with HIV are discriminated in the host communities and in healthcare sector institutaions. NGOs in collaboration with local governments have to provide special assistance, human rights protection and legal aid for IDPs with HIV at the local level.

## TUPED419

### THE FIGHT AGAINST STIGMA AND DISCRIMINATION IS NOT OVER: 53 COUNTRIES STILL HAVE HIV-SPECIFIC ENTRY AND RESIDENCE REGULATIONS FOR PEOPLE WITH HIV

P. Wiessner
*Action against AIDS, Policy and Communication, Berlin, Germany*
*Presenting author email: peter-wiessner@t-online.de*

**Background:** Beside global advocacy efforts from the HIV-Community 53 countries still have HIV-specific restrictions for entry and residence in place. Out of these 53 countries 27 deport or threaten to deport PLHIV, 11 categorically deny entry and 13 have laws that restrict entry even for short term stays in place. The situation contributes to the discrimination of PLHIV.
**Description:** The ongoing documentation of HIV-specific restrictions at entry and residence carried out by community-activists let the creation of global database HIV-specific restrictions at www.hivrestrictions.org. The gathered data from embassies around the world and the feedback from users of the database are an important source of information for mobile populations and foreign workers. The data demonstrate the relevance and importance of independent information, it contributes to the personal security and safety of PLHIV.
**Lessons learned:** The work demonstrates the importance of community-owned documentation. The "hype" around advocacy efforts is over or moved to other areas. When we started with this work 104 countries had restrictions in place. The situation certainly improved but its not over yet and its problematic to see that the global HIV-community other advocates does not address restrictions, for example in countries from the middle east that affect thousand of migrant workers, or uses upcoming sport events, like the World Cup in Qatar to mobilize communities while cross human rights violations against migrant workers in these countries are obvious.
**Conclusions/Next steps:** The current situation is discriminatory, a violation of human rights and a huge burden for PLHIV. States and in some cases intergovernmental organizations dent to downplay the impact of discriminatory laws. There might be silence around this topic since the successes celebrated with the revision of law in the US. Yet, the figures we have demonstrate that the fight against state-based discrimination is far from over.

# SOCIAL AND POLITICAL ADVOCACY AND MOBILIZATION

## TUPED420

### AN INVESTIGATION INTO THE FUNCTIONALITY OF THE PROVINCIAL, DISTRICT AND LOCAL AIDS COUNCILS IN LIMPOPO PROVINCE, SOUTH AFRICA

T.P. Mona, M.C. Raphahlelo, D.D. Segooa, R. Letsoalo, M. Ramufhi, M.R. Mugivhi, M. Chuma, N. Maja
*Limpopo Provincial Office of the Premier, AIDS Council Secretariat Unit, Polokwane, South Africa*
*Presenting author email: craphahlelo@gmail.com*

**Background:** The commitment of the South African Government to fight the spread of HIV is demonstrated through the existence of multi-sectoral AIDS Councils at National, Provincial and Local levels that serve to coordinate the AIDS response. The AIDS Councils in the Limpopo Province are governed by the Policy Framework. The purpose of this research was to investigate the functionality and effectiveness of the AIDS Councils in the Limpopo Province. The objectives were to identify challenges that hinder their effectiveness and to propose strategies to improve effectiveness of the co-ordination role. According to the Limpopo Provincial AIDS Council Policy Framework, AIDS Councils are considered to be functional if they are able to meet certain set criteria.
**Methods:** The study was conducted from May to July 2015, in all five districts of the Limpopo Province. The design of the research was descriptive and respondents were selected through purposive sampling. The study population consisted of HIV and AIDS co-ordinators. A semi-structured questionnaire and an AIDS Council functionality scale were distributed amongst 30 officials to gather both qualitative and quantitative data. The researchers applied composite frequency tables, pie and bar graphs to present quantitative data. Qualitative data was analysed through thematic analysis.
**Results:** The study revealed that AIDS councils are semi-functional in some Districts and Local municipalities, the capacity of AIDS Councils varies. Some of the challenges that hinder the functionality of AIDS Councils include the absence of dedicated secretariats, weak capacity of HIV and AIDS c-ordinators, competing priorities and irregularly held meetings. Various strategies were identified in order to deal with these challenges.
**Conclusions:** The functionality of AIDS Councils at all levels is crucial as it facilitates the multi-sectoral response. AIDS Councils also promote effective co-ordination of various structures so as to ensure that the goals of the Provincial Strategic Plan 2012-2016 are met.

## TUPED421

### LEAVING NO ONE BEHIND: AMPLIFYING VISIONS, VOICES AND PRIORITIES OF YOUNG MEN WHO HAVE SEX WITH MEN LIVING WITH HIV (MSM+) IN KISUMU COUNTY, KENYA

K. Olango
*Men against AIDS Youth Group, Health/Programmes, Kisumu, Kenya*
*Presenting author email: kenmasinya2003@yahoo.com*

**Background:** Research findings show high HIV prevalence among young MSM and are often unable to access HIV services, without facing stigma and discrimination based on age, gender, HIV status and sexual orientation as well as attitudes and norms around 'appropriate' sexual behaviour. Creating spaces to recognize the voices, visions and priorities of young MSM and meaningfully and directly engaging them in decision making on HIV, can increase their visibility, reduce their fear of isolation, increase treatment access and retention, and inform development of appropriate services.
**Description:** A group of 25 young MSM + between the ages of 17 to 24, were enrolled through patient support centers and support groups. They received training on advocacy and education and formed an advocacy network to conduct face -to-face dialogues with key stakeholders groups. The advocacy network called for policy makers to encourage and support young MSM to engage in the design, development, implementation, monitoring and evaluation of HIV programmes. They also called for training opportunities to enable young MSM+, to be become peer outreach workers, mentors and service providers themselves. They advocated decision makers invest resources in youth advocacy and support meaningful participation of young MSM+.
**Lessons learned:** "**Amplifying Visions, Voices and Priorities of Young MSM living with HIV**" has created spaces for increased involvement, increased their capacity to advocate, and better express their health needs. Programmatic evaluation indicated increased knowledge in meaningful involvement of communities' concepts, including young MSM+, along with transparency and accountability in health resource allocation and spending. Qualitative evaluation at the end of the campaign showed increased knowledge and practice related to establishment and access to youth friendly HIV services, status disclosure, partner testing and adherence.
**Conclusions/Next steps:** Empowerment of young MSM+ followed by advocacy campaigns has demonstrated opportunity to empower MSM+ to raise awareness about HIV, combat stigma / isolation, and inform development of services, and holistic approaches for their health. It has helped in reaching other young MSM+ in urban settings in Kisumu County.

## TUPED422

### THE "DRUG STOCK-OUT KILLS! STOP IT" CAMPAIGN: COALITION, DATA AND DIPLOMACY DRIVE RESULTS IN UGANDA

M. Dombo[1], K. Kade[2], D. Agaba[1], H. Naluyiga[1], S. Kentusi[3], S. Atim[3]
*[1]PATH, Kampala, Uganda, [2]PATH, Advocacy and Public Policy, Washington, United States, [3]National Forum of People Living with HIV Networks in Uganda, Kampala, Uganda*
*Presenting author email: mdombo@path.org*

**Background:** Between October and December 2015, due to a combination of unanticipated levels of patient enrollment and a weakening currency, Uganda faced a severe shortage of antiretroviral and anti-TB drugs. Approximately 250,000 patients were at risk of taking lower dosage drugs or none at all.
**Description:** The PATH-led USAID Advocacy for Better Health (ABH) project built a coalition of civil society organizations to elevate the looming stock-out crisis to the highest decision-making levels through an intensive, time-limited campaign. Key coalition activities included development of an up-to-date evidence dossier on district stock-outs; coordinated radio spots, press conferences and media tours; unique collaboration with the Inspector General of Police to organize face-to-face meetings with the Permanent Secretaries of Health and Finance and Speaker of Parliament; and strategic interface with advocacy champions, including representatives of the offices of the President and Prime Minister, First Lady, and a popular performing artist who publically disclosed their HIV status through the campaign. The government responded to the campaign with both short-and long-term measures. Ministry of Health redistributed drugs and front-loaded Global Fund budget for immediate purchase of drugs; Ministry of Finance and Parliament fast-tracked approval of a $200,000,000 loan and committed to increase the Ministry of Health's 2016/2017 budget. As stated by the Minister of Health, "The message had gotten home."
**Lessons learned:** Data and diplomacy were key to presenting the coalition as credible, collaborative, and solution-oriented. Evidence presentation was the focus of media and decision-maker outreach, while direct engagement with policymakers was perceived as yielding greater dividends than would have mass demonstrations. Consistent monitoring, data analysis and timely sharing of information ensured coalition members were armed with current findings and made message adherence and effective targeting possible. At the onset of ABH-project, decision-makers indicated that inaccurate information and combative approaches undermined CSO advocacy efforts. This intelligence informed ABH's choice of advocacy strategies.
**Conclusions/Next steps:** During short-term crises, campaigns cannot lose sight of long-term goals. Utilizing data and diplomacy, the campaign addressed the drug shortage, while positioning for ongoing decision-maker engagement, including securing commitments for quarterly dialogues as well as direct access to the Ugandan President if further stock-outs persisted.

## TUPED423

### PREVENTION LITERACY: COMMUNITY-BASED ADVOCACY FOR ACCESS AND OWNERSHIP OF THE HIV PREVENTION TOOLKIT

R. Parker[1,2], A. Perez-Brumer[1], J. Garcia[3], K. Gavigan[4], A. Ramirez[4], J. Milnor[4], V. Terto Jr.[2]
*[1]Columbia University, Sociomedical Sciences, New York, United States, [2]ABIA - Associação Brasileira Interdisciplinar de AIDS, Rio de Janeiro, Brazil, [3]Oregon State University, Corvallis, United States, [4]Columbia University, New York, United States*
*Presenting author email: rgp11@columbia.edu*

**Background:** Critical technological advances have yielded a toolkit of HIV prevention strategies. To take full advantage of these strategies, contextual and historical reflection is needed to bridge the gap from clinical efficacy to community effectiveness (i.e., knowledge and usage) of existing HIV prevention options.
**Methods:** Between January 2015-October 2015, we conducted a literature review to define treatment literacy and health literacy and assess the current need for literacy related to HIV prevention. The review included searches in electronic databases including, MEDLINE, PsycINFO, Pubmed, and Google Scholar. Permutations of the following search terms were used: ''treatment literacy'' ''health literacy'' and ''prevention literacy''. Through an iterative process of analyses and searches, titles, abstracts and reference lists of retrieved articles were reviewed for additional articles and historical content analyses of grey literature and websites were additionally conducted.
**Results:** In contrast to treatment literacy (TL), a well-established concept, prevention literacy (PL) was scarcely referenced and undertheorized in the available literature. While TL emerged due to shift in emphasis from prevention to treatment as more effective antiretroviral therapies became available, PL is absent in recent surge of biomedical prevention strategies. Developed from popular pedagogy and grassroots efforts during an intense struggle for treatment access, TL addressed the need to extend access to underserved communities and low-income settings that might otherwise be excluded from access. Prevention efforts today include multimodal techniques, which jointly comprise a toolkit of biomedical, behavioral, and structural/environmental approaches. However, linkages to community advocacy and mobilization efforts are limited and challenges of HIV prevention parallel the history of treatment roughly 15 years ago (e.g., increasing biomedical options, inequitable access, and efficacy that improves with strategies used in combination). Success of prevention efforts depends on equity of access, community-based ownership, and multilevel support structures to enable usage and sustainability.
**Conclusions:** For existing HIV prevention efforts to be fully utilized, an urgent need exists to reflect on historical lessons and contextual realities (i.e., policies, financial constraints, biomedical patents), extend treatment access and treatment literacy, and to build a new struggle for prevention literacy and prevention access as integral to the global response to HIV.

## TUPED424

### ASSESSMENT OF CLIENT'S SATISFACTION WITH PUBLIC SERVICES: HEARING COMMUNITIES' VOICES

D. Dmytriyev[1], I. Khryschuk[2], O. Bryzhovata[1], O. Vynogradova[1], T. Bryzhovaty[3], O. Gvozdetska[4]
*[1]All-Ukrainian Network of PLWH, Innovative Programs Unit, Kyiv, Ukraine, [2]All-Ukrainian Network of PLWH, Consultant on Sociological Research, Kyiv, Ukraine, [3]Charitable Foundation, Bethany Social Services, Kyiv, Ukraine, [4]All-Ukrainian Network of PLWH, Program Department, Kyiv, Ukraine*
*Presenting author email: d.dmitriev@network.org.ua*

**Background:** In 2013-2015 All-Ukrainian Network of PLWH implemented the project "Improvement of administrative services in social sphere in selected regions of Ukraine".
**Objectives:**
1. Building capacities of communities to monitor quality and integrity of public services.
2. Increase of civil society organization's (CSOs') capacities for building dialogue with state service providers on innovative approaches to services provision.

**Description:** The project covered 8 regions of Ukraine. Main activities:

1. Development of methodology and tools for assessing public services by representatives of HIV+ community.
2. Training of regional evaluators groups from local PLWH communities.
3. Assessment of recipients' satisfaction, data analysis, development of recommendations.
4. Creation of regional working groups for local opportunities and resources analysis to change service delivery in accordance with the evaluation recommendations.
5. Development and implementation of regional action plans that take into account local conditions and needs.

**Lessons learned:** Accomplishments of the project:
The methodology for assessing the quality of public services were developed, consisting of client's random interview to assess the satisfaction with services, on site assessment of services availability, mystery clients, and assessment of remote services delivery.
CSOs were involved in monitoring the government agencies. Evaluation of clients' satisfaction with public services was provided in 55 organizations, 5036 recipients of public services were interviewed.
Regional action plans were developed by the regional working groups for each project site. The groups consisted of the local authorities and CSOs representatives.
The developed regional action plans were adopted by the main stakeholders and taken as their development strategy basis.
The designed methodology of PLWH community involvement into services' quality evaluation is universal and can be applied in all areas related to the provision of public services.
**Conclusions/Next steps:** Plans for the future:

- Dissemination of the project results to other regions of Ukraine and in other areas of public services.
- Regular involvement of PLWH in public agencies monitoring.
- Implementation of mechanisms to improve the availability of public services through advocacy and collective representation of interests by PLWH community.

## TUPED425

### Where are the men? Addressing the global blind spot around heterosexual men in the HIV pandemic

L. Pascoe, D. Peacock
*Sonke Gender Justice, Cape Town, South Africa*
*Presenting author email: dean@genderjustice.org.za*

**Background:** A growing body of evidence shows that men—of all sexualities but in particular heterosexual men—are significantly underrepresented in HIV and AIDS testing and treatment services but overrepresented in morbidity and mortality data—both in Sub-Saharan Africa and globally. HIV infections among men make up 52% of all new HIV infections globally. Studies consistently show that men's testing is lower than women's in most settings. When men do not know their HIV status, they are more likely to engage in unsafe sex practices and are thus much more likely to transmit HIV to their partners. They are less likely to access and adhere to treatment and more likely to need ongoing care and support—burdens that detrimentally impact women as well as health systems. Men constitute almost 60% of AIDS-related deaths globally, and make up the majority of AIDS-related deaths in every region of the world. Young men are twice as likely to die an AIDS-related than HIV-infected adolescent women.
**Description:** Men's low demand for and utilization of HIV services is a combination of socio-behavioural and structural factors. If the UNAIDS goal of 90-90-90 by 2020 is possible, it is pressing to increase men's use of HIV services, and improve the supply and efficacy of HIV testing, treatment, and adherence services. Critically, this includes engaging men and boys in gender transformation. In this presentation Sonke Gender Justice will discuss evidence-based practices to increase men's use of and access to services, and propose policy and programmatic changes to promote.
**Lessons learned:** Key recommendations include the development of new policies and policy guidelines, community-based testing services, partner and workplace testing, self-testing, clinic navigators, male-only facilities or male-only hours, mass scale up of male circumcision, gender transformative small group and mass media interventions, and community mobilisation strategies.
**Conclusions/Next steps:** If the global community stands a chance of curbing the AIDS epidemic, it is critical to address the gender norms—and the structural manifestations of these norms—that deter men from seeking much needed HIV prevention, treatment and care services.

## TUPED426

### Regional concept notes: lessons from the first window of Global Fund submissions

K. Richardson[1], C. Baran[1], S. Mellors[2]
*[1]ICASO, Toronto, ON, Canada, [2]International HIV/AIDS Alliance, Brighton, United Kingdom*
*Presenting author email: charlie.baran@gmail.com*

**Background:** Regional programs supported by the Global Fund to Fight AIDS, TB and Malaria provide a unique and critical space for advocacy for key populations. In 2015, ICASO and the Alliance synthesized lessons learned from regional concept notes (RCNs) submitted in 2014. The project documented case studies from three regions: Eastern Africa, Southern Africa, and the Middle East & North Africa and drew lessons learned and recommendations for improvement.
**Description:** This project was conducted between December 2014 and May 2015, including the concept note submission deadline of January 31, 2015. Desk research included reviews of relevant documents, such as draft and final concept notes, meeting minutes, and communications. Key informant interviews were conducted with a range of persons involved, including key population network representatives, proposed principal recipients, consultants, technical partners, and other stakeholders. An interview guide was developed and used for phone interviews. Once completed, the project increased understanding among key stakeholders of the time and financial investment involved in RCN development and highlighted the technical support needs for future submissions windows.
**Lessons learned:** Regional programs address contextual concerns such as reductions of HIV incidence and building the capacity of key population networks, and offer opportunities for civil society that may not be a given in national programs, especially where the political will does not exist to tackle stigma and discrimination. Yet the regional programs are burdened with the same requirements for concept note development, as those of national programs. The country coordinating mechanism/National AIDS Program endorsement requirement also presents a substantial drain. Overall, opportunities exist to increase efficiency, offset by the dire need to increase RCN-development funding allocations to better align the costs associated with the process. Finally, it should be recognized that few key population networks have the capacity to develop and lead RCN development. Capacity development for civil society organizations and key population networks should be integral to the RCN process.
**Conclusions/Next steps:** The regional program model fills an important gap and should be continued in the Global Fund's next strategy 2017-2022. Increased technical and financial support should be provided to key populations involved in RCN processes to truly enable their meaningful involvement.

## TUPED427

### Delivering HIV-related community, structural and service development interventions for men who have sex with men in Kenya, Tanzania, Uganda and Zimbabwe: an appraisal of the SHARP programme

A. Bourne[1], E. Fearon[1], W. Nutland[1], C. Dorval Deffarary[2], G. Reid[2]
*[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]International HIV/AIDS Alliance, Brighton, United Kingdom*
*Presenting author email: adam.bourne@lshtm.ac.uk*

**Background:** In Kenya, Tanzania, Uganda and Zimbabwe, homosexuality is illegal, subject to severe social stigma and discrimination, and often coupled with state-sponsored violence. This environment hampers HIV prevention efforts among men who have sex with men (MSM), who are at a heightened risk of acquiring HIV. The Sexual Health & Rights Programme (SHARP) comprised a number of interventions that aimed to improve the social and political environment within which MSM live, and sensitise clinical services to the specific health and social care needs of MSM. This paper reports on a detailed appraisal of such interventions.
**Methods:** Adopting a rapid feedback approach, the study assessed each discrete intervention in relation to effectiveness, coverage, need, acceptability, feasibility, acceptability and cost. Data was collected via interviews and focus groups with staff and volunteers from seven SHARP-supported MSM-led community based organisations (CBOs) who deliver HIV prevention and care interventions to MSM and analysis of routine monitoring data. Triangulation was facilitated by interviewing other local stakeholders familiar with the interventions delivered and their integration with other health and social care systems.
**Results:** Recognising the need for credible allies, all CBOs in SHARP had, following in-depth sensitisation training, partnered with state sanctioned clinical care providers to allow safe referral pathways to MSM in their localities. This had improved accessibility of sexual health services, although the nature of syndromic-only screening still posed a risk of missed STI diagnoses. Many CBOs have also achieved success in their engagement activities by starting from a position of facilitating holistic well-

being; providing safe spaces for socialising and resilience building among MSM. While some success in policy and lobbying efforts to improve the legal environment has been achieved, significant challenges still remain in safely gaining access and maintaining relationships to key decision makers in shifting political climates.
**Conclusions:** MSM led organisations have earned the trust of large sections of the community and are well-placed to facilitate access to health and social services essential to the well-being of MSM. While essential to the HIV response, both the successes and shortcomings of policy and lobbying interventions should be considered within the broader, largely hostile, political environment for MSM.

## COUPLES- OR FAMILY-CENTRED APPROACHES

### TUPED428

### FAMILY CENTERED APPROACHES: REACHING SPOUSES, COUPLES AND FAMILIES FROM THE WORKPLACE

E. Maziofa-Tapfuma[1], J. Viner[2]
*[1]Swedish Workplace HIV/AIDS Programme, HIV/AIDS, Harare, Zimbabwe, [2]Swedish Workplace HIV/AIDS Programme, HIV/AIDS, Stockholm, Sweden*
*Presenting author email: edith@swhap.org*

**Background:** Workplaces in most sectors in Sub Saharan Africa are largely dominated by men. 90% of employees in companies supported by the Swedish Workplace HIV&AIDS Programme are male, thus resulting in disproportionate access to HIV & AIDS information and services among men and their spouses. Gender inequalities still largely exist. These inequalities result in women being economically dependent on men putting women & men at further risk. Economic dependency of women on men limits ability to negotiate for safe sex.
**Description:** The main objective of the Family centered approach was to close the gap in access to information, prevention services, access to HTS and treatment between the employed men with their spouses and children. When a shared understanding and awareness of HIV & AIDS was created among workers and their spouses, an enabling environment for discussing issues such as safer sex, partner counseling, Couple testing and voluntary disclosure of HIV status was created at family level.
**Lessons learned:**
1. The information gap between spouses/partners regarding HIV transmission, progression, prevention and management was significantly reduced.
2. Inclusion of families in family wellness days increased uptake of HIV & AIDS testing as well as couple testing. On average uptake of testing in SWHAP
3. Spouses volunteered and were trained as community Peer Educators and Community Psycho social Counselors.
4. Formation of spousal clubs which evolved into income generating projects receiving technical and financial support from the companies
5. Parents equipped with skills to encourage in sexual communication with their adolescent children promoting delayed debut and responsible sexual behavior
6. Ripple effects have included spreading of HIV & AIDS information at community level; Some of the trained spouses also volunteer their services at the local clinics

**Conclusions/Next steps:**
1. Inclusion of families into programs promote acceptability of workplace programs
2. Inclusion of families promote increased uptake of testing, treatment and uptake of supplementary/nutritional support to affected families
3. Inclusion of families results in greater openness and voluntary disclosure of HIV status
4. Trained spouses are also taking the lead in community outreach programs to further spread information on HIV and promote testing.

### TUPED429

### ACCEPTABILITY OF WOMAN-DELIVERED HIV SELF-TESTING TO THE MALE PARTNER: A QUALITATIVE STUDY OF ANTENATAL CLINIC-LINKED PARTICIPANTS IN BLANTYRE, MALAWI

A.T. Choko[1,2], M. Kumwenda[1,3], K. Fielding[2], E. Corbett[1,4], J. Chikovore[5], N. Desmond[6,7]
*[1]Malawi Liverpool Wellcome Trust Clinical Research Programme, TB/HIV, Blantyre, Malawi, [2]London School of Hygiene & Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom, [3]University of Malawi, College of Medicine, Helse-Nord TB Initiative, Blantyre, Malawi, [4]London School of Hygiene & Tropical Medicine, Clinical Research, London, United Kingdom, [5]Human Sciences Research Council, Pretoria, South Africa, [6]Liverpool School of Tropical Medicine, Clinical Sciences, United Kingdom, [7]Malawi Liverpool Wellcome Trust Clinical Research Programme, Social Science, Blantyre, Malawi*
*Presenting author email: augutc@gmail.com*

**Background:** High rates of HIV transmission within established sexual relationships in Africa call for high uptake HIV testing strategies that reach both partners. HIV self-test (HIVST) kits enable novel strategies, including partner-delivered kits to encourage testing as a couple at home. We explored the acceptability of using antenatal clinics (ANCs) as recruitment points, building on strong PMCTC programmes in Malawi. We sought the views of women attending ANC and their male partners concerning partner-delivered HIVST kits, either alone or with different approaches aimed at encouraging subsequent linkage into care or prevention.
**Methods:** A formative qualitative study to inform the design of a trial including five focus group discussions (2 men only; 2 women only; and 1mixed gender) was done with a total of 36 participants. Thematic content analysis was used to interpret the data.
**Results:** Providing HIVST kits to pregnant women to deliver to their male partners was highly acceptable to both women and men. Several men strongly preferred this approach to any alternative, as this allowed testing to fit into lifestyles that are characterised by extreme day-to-day economic pressures, including need to raise money each day for food. Both men and women disagreed that introducing woman-delivered HIVST would provoke intimate partner violence (IPV), stating that pregnant women should be culturally "immune" from IPV. Most men stated a preference to self-test alone, ideally followed by the opportunity to re-self-test as a couple.
Regarding interventions for optimising linkage, both men and women felt that fixed financial incentives of ~ USD$2 would increase linkage. However, there were concerns: potential negative consequences included a perceived undue reward for having multiple pregnant partners if financial incentives were too high. A lottery incentive was considered overly disappointing for those who receive nothing towards their evening meal in this extremely poor setting. Phone call reminders were preferred to short messaging service (SMS), given the frequency of "junk" SMSs in this setting.
**Conclusions:** Partner-delivered HIVST through antenatal clinic was acceptable to both men and women. Feedback on additional linkage enablers will be used to alter pre-planned trial arms. Lottery-based interventions may not be as effective in settings with extreme poverty.

### TUPED430

### PREPARING AND SUPPORTING CAREGIVERS IN THE HIV DISCLOSURE PROCESS TO INFECTED CHILDREN AND ADOLESCENTS: LESSONS FROM THE YËGËL PILOT INTERVENTION IN SENEGAL

F. Hejoaka[1,2,3], M.L.I. Souane[4,5], E.H. Diom[4,5], N. Mbaye[4], A. Diack Mbaye[6], C. Cames[1,3], A. Fall[4], H. Sy Signate[6], N. Lachina[6], A. Diop[6]
*[1]Institut de Recherche pour le Développement, UMI 233 TransVIHMI / INSERM U1175, Montpellier, France, [2]Université de Lorraine, CREM EA 3476, Nancy, France, [3]Centre de Recherche Clinique et de Formation, Hôpital de Fann, Dakar, Senegal, [4]Synergie pour l'Enfance, Guédiawaye, Senegal, [5]Hôpital Roi Baudoin, UPSA, Guédiawaye, Senegal, [6]Centre Hospitalier National d'Enfants Albert Royer, Dakar, Senegal*
*Presenting author email: fabienne.hejoaka@ird.fr*

**Background:** In accordance with WHO guideline on HIV disclosure counselling for children up to 12 years of age (2011), we developed a pilot intervention (YËGËL) in Senegal to prepare and to support caregivers (i.e. parents and primary careers) throughout the challenging process of paediatric HIV disclosure to infected children and adolescents. The communication describes the family-based pilot intervention and four main lessons learned.
**Description:** Between April 2013-October 2015, following a socio-anthropological study identifying institutional and parental barriers to paediatric HIV disclosure, the YËGËL pilot intervention was designed and implemented in two paediatric services in Senegal.

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

30 caregivers of children and adolescents aged from 9 to 15 years were included in the pilot intervention, which included four main components:

1. Over two 2-hour sessions, the preparation of caregivers in peer-groups, informing them about: reasons for disclosure, potential positive and negatives outcomes, negative consequences of non-disclosure, children's HIV awareness and their capacities for secrecy, potential reactions to disclosure, parental shame, fear of rejection and felt-stigma, as well as explanations of the disclosure process
2. Testimonies from parents and peer-adolescents with prior experience of disclosure
3. Parents' participation in a 2-hour child peer-group aimed at preparing them for disclosure, by using children's drawings, images and videos as visual supports.
4. With caregivers' consent, disclosure performed by professionals

**Lessons learned:** 24 caregivers (77% women) out of 30 total completed the four components and disclosed to children. The four main lessons learned were:

1. Synergic effects on caregivers' prepardness of the comprehensive approach, including parental information and support, disclosure performed by professionals and children's collective preparation for full disclosure
2. Peer-groups of caregivers and children fostered collective dynamics, social support and limited of isolation
3. Disclosure performed by professionals strongly helped untrained and emotionally affected caregivers to decide to inform children
4. Parent participation in children's peer-groups facilitated their acceptation of children's readiness to learn of their diagnoses and enhanced intergenerational communication on HIV/AIDS and antiretroviral treatment.

**Conclusions/Next steps:** The YËGËL project demonstrates the acceptability and feasibility of a family-based pilot intervention that prepares and supports caregivers during the all process of paediatric HIV disclosure in Senegal. Results should be evaluated at larger scale in randomized studies.

## COMPREHENSIVE SERVICES FOR THE PREVENTION OF VERTICAL TRANSMISSION, INCLUDING EARLY CHILDHOOD DEVELOPMENT, CHILD CARE AND NUTRITION SUPPORT

### TUPED431

#### EFFECTIVENESS OF A PREVENTION OF MOTHER TO CHILD TRANSMISSION PROGRAM AT BHARATPUR HOSPITAL, CHITWAN, NEPAL

U. Shrestha
*Bharatpur Hospital, ART Center, Bharatpur, Nepal*
*Presenting author email: drunnat@gmail.com*

**Background:** Nepal has a low concentrated epidemic with about 736,000 pregnancies every year (Nepal Report, 2012). The primary cause of pediatric HIV infection is mother-to-child transmission (MTCT), which can be reduced significantly by interventions that include antiretroviral (ARV) therapy and prophylaxis. Prevention of mother-to-child transmission (PMTCT) programs serve as critical entry points for the provision of HIV testing and treatment, though few of these programs exist in resource-limited settings in Nepal.

**Methods:** Data was collected through a retrospective review of medical records of pregnant women who accessed antenatal and delivery services at Bharatpur Hospital from 2011-2015. In the study period, all 53,258 pregnant women registered in the Antenatal Care (ANC) accepted testing. A supplementary review of pregnant women with no prior history of HIV testing was conducted to evaluate HIV testing at delivery. Finally, an analysis of rapid testing and infant DNA Polymerase Chain Reaction (PCR) testing was conducted to assess rates of follow-up testing among HIV-exposed infants.

**Results:** High rates of antenatal testing resulted in early detection of HIV infection among pregnant women. There were high rates of ART initiation among mothers and ARV prophylaxis in infants. Out of 70 newborns registered, 3 died, 67 received 6 weeks of Neverapine prophylaxis and 63 babies completed the protocol. At 6 weeks from the birth, post DNA PCR testing was done among babies. Only 2 infants were HIV positive and both of these 2 infants started ART. And 61 were HIV negative and the MTCT risk was 2.98%. The study shows a good level of enrollment with good drug adherence.

**Conclusions:** Enrollment in PMTCT, high rates of HIV testing during pregnancy, early initiation of ART and prophylaxis to HIV exposed newborns proved successful during the PMTCT program. Linkage to service delivery at the ART center and NGOs resulted in minimum lost to follow up and higher testing among HIV exposed infants. It demonstrates that ARV regimens can be implemented in low resource rural settings with marked decreases of MTCT. Increasing the coverage of PMTCT programs remains the primary challenge.

## INCENTIVES, MICRO-FINANCE AND OTHER ECONOMIC SUPPORT

### TUPED432

#### THE PROMISE OF BEHAVIORAL ECONOMICS FOR HIV/AIDS TREATMENT AND CARE

R. Buzdugan[1], S. Bautista-Arredondo[2], S. McCoy[1]
*[1]University of California, School of Public Health, Berkeley, United States, [2]National Institute of Public Health, Health Economics Department, Cuernavaca, Mexico*

**Background:** New strategies are needed to motivate behavior change on the HIV treatment and care cascade. Behavioral economics (BE) offers potential innovative approaches. BE provides a realistic model to explain individuals' decisions by combining insights from psychology with microeconomic theory.

**Methods:** We conducted a rapid systematic review of studies evaluating the effectiveness of interventions using BE to improve uptake of HIV testing, linkage to care, retention in care, and antiretroviral therapy (ART) adherence among people living with HIV. We searched MEDLINE/Pubmed (2010-2015) for experimental or quasi-experimental studies or prior reviews of interventions using BE approaches, including: financial or in-kind incentives, contingency management, nudging, priming, and gamification. Our analysis focused on identifying the effectiveness and durability of BE approaches.

**Results:** We identified 27 eligible studies.

HIV testing: Three demand-side studies and one supply-side study examined the effect of financial incentives on HIV testing and all found significant positive effects.

Linkage to care: One study found that incentives significantly increased linkage to care.

Retention in care: Five studies examined the effect of BE applications on retention in care: one study using vouchers, one study of a comprehensive intervention that included food and transport assistance, two studies using food rations, and one study that changed the default structure for clinic visits. All five studies reported significant positive effects.

ART adherence: We found 20 studies: nine studies assessed financial incentives, and eleven assessed in-kind incentives (prizes (n=2), cell phones or cell phone plans (n=2), food rations (n=5), or community-based interventions including food and transportation assistance (n=2)). One intervention using financial incentives also incorporated gamification. Eight of the nine studies examining financial incentives had positive results, significantly increasing adherence. Studies examining food rations had mixed results. The six other studies had positive results. Seven studies on adherence assessed impact durability after incentives were withdrawn; two of them found positive effects post-intervention.

**Conclusions:** BE applications have demonstrated potential to enhance HIV treatment and care services. However, there is limited evidence about impact durability. Furthermore, most studies focused on financial and in-kind incentives; the full range of BE applications (e.g., priming, gamification, nudging) should be explored and incorporated in future interventions.

### TUPED433

#### CASH TRANSFERS FOR HIV PREVENTION IN YOUNG SOUTH AFRICAN WOMEN: WHAT DO THEY SPEND IT ON? HPTN 068 TRIAL

C. MacPhail[1,2,3], N. Khoza[2], A. Selin[4], A. Julien[5], K. Kahn[3,6,7], R. Wagner[3], X. Gómez-Olivé[3], A. Pettifor[2,3,5]
*[1]University of New England, School of Health, Armidale, Australia, [2]Wits Reproductive Health and HIV Institute, University of the Witwaterstrand, Johannesburg, South Africa, [3]University of the Witwatersrand, MRC/Wits Rural Public Health and Transitions Unit, School of Public Health, Johannesburg, South Africa, [4]University of North Carolina, Carolina Population Center, Chapel Hill, United States, [5]University of North Carolina, Department of Epidemiology, Chapel Hill, United States, [6]Umea Centre for Global Health Research, Umea, Sweden, [7]INDEPTH Network, Accra, Ghana*
*Presenting author email: aselin@une.edu*

**Background:** Worldwide, cash transfers have traditionally been paid to adult women. Evidence from programmes providing cash transfers to adults has suggested that payments to women are likely to be used for the greater good of households, while payments to men may result in negative outcomes. More recently, research has examined the potential for using cash transfers for HIV prevention among adolescent women in sub-Saharan Africa. In the context of concerns about social grants in South Africa, we explored how cash transfers are spent by adolescent women.

**Methods:** HPTN 068 was a 3-year randomized controlled trial to assess the impact of a cash transfer, conditioned on school attendance, on HIV incidence among young rural South African women. 2328 13-20 year old women were recruited and completed annual survey assessments.

A longitudinal qualitative cohort was created with a sub-sample of 71 women (38 from intervention arm). Female, local language-speaking fieldworkers interviewed

young women twice annually. Interviews were recorded, translated and transcribed for coding and analysis in Atlas.ti.
**Results:** At each survey visit, young women reported their cash transfer spending. Cash transfer was mainly spent on toiletries (55.5%). This was followed by clothes (34.5%), school uniform or supplies (29.9%), mobile phones/ airtime (29.3%), and hairdressing (28.9%). Spending on 'negative' items such as alcohol was very low (2.3%) and saving cash was rare. The qualitative data corroborated this information and suggested that 'snacks at school' was also a significant expenditure. There were almost no reports of negative impacts associated with receiving the cash. Indeed, the cash transfers were viewed as positive in terms of improving family relationships (especially with mothers), empowering young women through greater independence and facilitating peer acceptance through access to material goods.
**Conclusions:** Evidence from this study found no negative impacts of providing adolescent women with cash transfers; both in terms of spending and provision of cash to young women in impoverished environments. This corroborates previous research in which payment of social grants to adult women was not found to facilitate negative outcomes and suggests limited concerns with making payments to this young population.

## TUPED434

### MOTIVATING ADOLESCENTS TO TAKE POSITIVE RESPONSIBILITY FOR THEIR LIVES: LESSONS LEARNED FROM IMPLEMENTING A CONDITIONAL CASH-TRANSFER INTERVENTION IN THREE COUNTRIES IN SOUTHERN AFRICA

S.B. Ndlovu, J. Norins
*MIET Africa, Regional Programmes, Durban, South Africa*
*Presenting author email: jen@miet.co.za*

**Background:** RHIVA is a school-based HIV prevention pilot project that aims to assess the effectiveness of two levels of intervention (Intervention 1: conditional cash transfer; and Intervention 2: conditional cash transfer plus enhanced life-skills materials) in changing adolescents' behavior regarding their sexual reproductive health (SRHR) and their economic future, and ultimately to reduce HIV infections among this vulnerable group.
**Description:** The RHIVA program was implemented in Mozambique, Namibia and Zambia from February 2014 to December 2015, and involved 3374 learners in Grades 9-12. Each year, learners received cash transfers of 20 USD for each of four milestones achieved, which include knowing their status (HCT) and academic performance. In addition, learners in Intervention 2 were exposed to "My life! My future!" materials that comprise youth-friendly SRHR and career development components.
**Lessons learned:** Although summative evaluation is currently on-going, preliminary evidence suggests that the incentive model is promoting a positive change in learners' attitudes and behaviors toward their sexual reproductive health and their future. HCT uptake was high in Namibia and Zambia, as demonstrated by the percent of learners who achieved the Know Your Status milestone (83% in Year 1, and 77% in Year 2). Success stories of learners point to significant life changes, such as ending intergenerational relationships, as a result of the cash transfer. Key lessons derived from the pilot include:
1) rigorous data management and compliance is critical for monitoring the HCT uptake among adolescents and assessing the impact of the intervention;
2) implementing in different settings requires additional care to the cultural nuances that affect successful implementation;
3) testing non-monetary incentives can assist in understanding what incentivizes adolescents to engage in positive behavior.
**Conclusions/Next steps:** Preliminary evidence suggests that cash incentives provide strong motivation to learners to take responsible action for their sexual reproductive health and for their schooling. However, the feasibility of funding a scaled up program poses a challenge for governments. More research is needed to determine the effectiveness of different incentive models, and whether the incentive model leads to prolonged behavior change after the incentives have stopped, thus resulting in a greater benefit for the investment made.

# SAFE HOUSING, SOCIAL PROTECTION AND OTHER CARE AND SUPPORT FOR THOSE AFFECTED BY HIV

## TUPED435

### HOUSING IS HEALTH: EVIDENCE OF THE IMPACT OF HOUSING ON HIV HEALTH OUTCOMES FROM A HARM REDUCTION HOUSING PROGRAM

E. Bowen[1], J. Canfield[2], S. Moore[3], C. Rademacher[3], M. Hines[3], B. Hartke[3]
*[1]University at Buffalo, School of Social Work, Buffalo, United States, [2]University of Cincinnati, School of Social Work, Cincinnati, United States, [3]Caracole, Inc, Cincinnati, United States*
*Presenting author email: eabowen@buffalo.edu*

**Background:** Prior research has demonstrated that stable housing is a key social determinant of the health of persons living with HIV/AIDS (PLWHA). In the U.S. and other countries, economic and social factors (e.g. substance use and criminal justice system involvement) often contribute to homelessness and housing instability among PLWHA. This program analysis describes an innovative harm reduction housing program and its impact on HIV health outcomes for homeless PLWHA in a small U.S. city.
**Description:** The program, Caracole, provides a scattered site supportive housing to homeless PLWHA in Cincinnati, Ohio, USA. Two years ago, the program adopted a "housing first" harm reduction-based approach to promote housing stability. The housing team includes case management, specialized housing support, and optional mental health services. The team coordinates services with a variety of other providers to meet participants' holistic health and housing needs. These service partners include the local syringe exchange program, Planned Parenthood for testing and HIV education, medical treatment providers, mental health and substance abuse treatment agencies, shelters, outreach workers, and other housing programs.
**Lessons learned:** Program data demonstrates the importance of supportive housing for HIV health. Of 150 formerly homeless participants housed in the program between 2000 and 2015, the percent of participants achieving a healthy t-cell count (>500) increased from 40% at intake to 59% at last status. Participants achieving undetectable viral load increased from 62% at intake to 72% at last status. The majority of participants (72%) also maintained or increased income and decreased contact with the justice system. Adopting a harm reduction approach increased participants' housing stability and was associated with better HIV health. For example, average housing tenure for participants with a healthy t-cell count was 3.9 years, compared with 2.6 years for participants with low t-cell counts.
**Conclusions/Next steps:** Safe and supportive housing is key to the health of PLWHA. This analysis demonstrates that harm reduction housing programs may help individuals stay stably housed and improve outcomes along the HIV/AIDS treatment cascade. Further research-practice collaborations should examine best practices for increasing housing stability and the impact of these practices on HIV-related and other health and social outcomes.

## TUPED436

### HITS AND MISSES OF SOCIAL PROTECTION: FINDINGS OF A HIV-SENSITIVITY COMPARATIVE ANALYSIS OF GOVERNMENT AND CSO SOCIAL PROTECTION INTERVENTIONS IN KENYA

A.J. Bwonderi[1,2]
*[1]Technical University of Mombasa, Health and Environmental Sciences, Mombasa, Kenya, [2]Centre for Research and Development, Programmes and Advocacy, Nairobi, Kenya*
*Presenting author email: aungonderi@gmail.com*

**Background:** HIV Prevalence in Kenya has a dialectical relationship with socioeconomic vulnerability in sub-Saharan. A lack of resources compromises livelihood and survival systems; which in turn creates concurrent financial and structural drivers and barriers to prevention, care and treatment services. Social protection (SP) aims to create a safety net and reinforce socio-economic stability, breaking the link between poverty and HIV transmission while simultaneously ameliorating the financial impact of HIV and AIDS' on poor households. The Kenyan Government (GOK) promotes cash transfer-based-(CT) SP while NGO-led programs adopt the OVC livelihood strengthening(LS) strategy to support HIV/AIDS management among vulnerable households.
**Methods:** The analysis examined and compared government-led CT and CSO Livelihood support interventions in order to inform design of comprehensive HIV-responsive SP models for addressing vulnerability across HIV/AIDS prevention continuum among the poor.
This comparative analysis gathered qualitative data through 5 FGD with CT beneficiaries, community health volunteers; support groups; community leaders, and OVC caregivers using FGD guides. Program narrative reports from the APHIAPlus

**Tuesday 19 July** Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

Nairobi Coast covering 5 Coastal counties (2013-2015) and extensive literature were included in the analysis using Nvivo software.

**Results:** GoK CT programs support vulnerable households- elderly, disabled and orphaned in general while CSO-led interventions promote livelihood support activities for HIV OVC caregivers irrespective of individual OVC differences. CT provides stipends on monthly basis to subsist basics needs. LS provides food, clothing and scholastic materials (direct support) and seed capital for initiating IGAs (care givers). Both approaches have improved capacity for basic needs provision for vulnerable households. Both ignore structural issues -GBV, stigma and discrimination affecting HIV/AIDS prevention and management hence are mildly sensitive to HIV-related vulnerability.

**Conclusions:** Both approaches to SP are inadequate in comprehensively addressing needs of HIV-related vulnerability. They lack comprehensive and integrated programming across the interventional continuum: protective-preventive-promotive-transformative; that focus on sustainability, short-term and long term-needs; exclusion, GBV, discrimination and stigma. Effective SP should focus on stigma, rights protection socio-economic livelihoods; accessible, quality and reliable preventive, treatment, care and supportive health services.

## DEVELOPMENT AND POVERTY ALLEVIATION

### TUPED437

### *FINDING THE LEADER WITHIN:* EXPERIENCE AT THE BOTSWANA-BAYLOR CHILDREN'S CLINICAL CENTRE OF EXCELLENCE (COE)

M. Matshaba[1,2], M. Mosweunyane[1], G. Karugaba[1], G. Anabwani[1,2]
*[1]Botswana-Baylor Children's Clinical Centre of Excellence, Gaborone, Botswana, [2]Baylor College of Medicine, Pediatrics, Houston, United States*
*Presenting author email: matshaba@bcm.edu*

**Background:** Due to widespread antiretroviral roll-out, children born with HIV are now surviving into adolescence and young adulthood. As they age, they are faced with new challenges including poor academic achievement and unemployment. In 2013, the Baylor COE opened the Baylor Bristol-Myers Squibb Phatsimong Adolescent Centre housing adolescent services, psycho-social support, library, computer labs and sports court - as a resource to support and rehabilitate adolescents with or without HIV using various interventions including *Finding the Leader Within*.

**Methods:** *Finding the Leader Within* is a year-long leadership program for out-of-school youth aged 16-25 years. The program was implemented in partnership with Stepping Stones International (SSI), a non-profit organization based in Mochudi, Botswana. The program ran four days a week and the curriculum was designed to give participants skills to gain meaningful employment (full-time, salaried). Participants completed lessons in leadership development, career and vocational development, healthy and productive lifestyle education, financial and business literacy, computer literacy, and optional English class. To graduate, participants were required to successfully complete at least 80% of the curriculum. Trainers included adolescent services staff, social workers, clinical psychologist and vocational facilitators. Seed funding was provided by SSI.

**Results:** In April 2015, a founding class of 38 out-of-school youth aged 18 to 25 (24 Female) were enrolled. Their highest education levels were: primary (1) ; junior secondary (21), senior secondary (14), and part tertiary (2). In the end, 28 of 38 (74%) completed a minimum of the required 80% of the curriculum..The 10 drop-outs left the program early without completing 25% of the curriculum for various reasons: found meaningful job (4), went back to school (1), became ill (1), and unknown (4).

**Conclusions:** *Finding the Leader Within* is an effective intervention for school drop-outs. Maximizing the outcomes of the Leadership Program calls for skilled facilitators, diversifying skills training, securing adequate funding, and employing a full-time coordinator, and developing connections with employers in the community.

### TUPED438

### COMMON THREADS: A PEER-LED INTEGRATED PREVENTION, TRAUMA-INFORMED AND VOCATIONAL DEVELOPMENT TRAINING FOR WOMEN LIVING WITH HIV

V. Johnson[1], L. Scruggs[2]
*[1]Ribbon Consulting Group, Washington, United States, [2]Ribbon Consulting Group, Largo, MD, United States*
*Presenting author email: vjohnson84bj@gmail.com*

**Background:** The objective of this presentation is to increase awareness and skills related to the need to implement trauma-informed vocational and HIV prevention interventions for African American women with HIV. Common Threads recognizes the impact of poverty and limited access to resource increase vulnerability to HIV transmission, especially for African American women who encounter numerous social and economic barriers. By addressing the underlying trauma and other economic and social vulnerabilities to HIV, the goals of Common Threads are to increase self-esteem, HIV self-management, and vocational skills. These goals are highly associated with increased engagement in care, reduction in HIV transmissions and reduced health disparities.

**Description:** Common Threads is an integrated HIV prevention and vocational intervention program for African American women living with HIV/AIDS, which respond to the impact of trauma on women living with HIV and their vocational development. In addition to providing an overview of the Common Threads program and research that supports this approach, this presentation will utilize interactive activities to support an engaging and positive environment.

**Lessons learned:** Both quantitative and qualitative data related to program outcomes will be shared. We will report quantitative data for an initial program evaluation that indicates that participants gained knowledge on health prevention, demonstrated a decrease in HIV-related stigma and increased engagement in health care. Participants also reported increased willingness to disclose their HIV status and share their life experiences with friends, family, and their community members. They also indicated increased financial and social stability.

**Conclusions/Next steps:** Current policies and initiatives call for further integration of social determinants of health into HIV/AIDS prevention and care interventions. Poverty, stigma, and the lack of social support are fueling the transmission of HIV, especially among African American women who face multiple medical, psychosocial, financial/legal and vocational vulnerabilities that limit their access to HIV care and the opportunity to pursue personal and financial empowerment.

## TACKLING STIGMA AND STIGMA REDUCTION INTERVENTIONS

### TUPED439

### "THINGS PEOPLE SAY:" ENHANCED STIGMA REDUCTION TRAINING REDUCES HIV-RELATED STIGMA AMONG HEALTHCARE PROVIDERS PROVIDING SERVICES TO YOUNG PEOPLE AFFECTED BY HIV IN BANGLADESH

S. Geibel[1], S. Hossain[2], J. Pulerwitz[1], N. Sultana[2], T. Hossain[2], B. Friedland[3], B. Zieman[1], R. Yasmin[4], N. Sadiq[5], L. Stackpool-Moore[6], E. Yam[1]
*[1]Population Council, Washington, United States, [2]Population Council, Dhaka, Bangladesh, [3]Population Council, New York, United States, [4]Marie Stopes Bangladesh, Dhaka, Bangladesh, [5]International HIV/AIDS Alliance, Dhaka, Bangladesh, [6]International HIV/AIDS Alliance, Brighton, United Kingdom*
*Presenting author email: sgeibel@popcouncil.org*

**Background:** HIV-related stigma can inhibit the uptake of critical HIV and sexual and reproductive health and rights (SRHR) services, particularly among young people. Working with health providers to reduce HIV stigma in the healthcare setting is an important strategy to improve service utilization and quality of care. The Link Up project—through partners Marie Stopes Bangladesh (MSB) and Link Up Bangladesh—implemented a stigma reduction training program for health providers, aiming to improve service quality for young people at higher risk (e.g. sexually active, sex workers, sexual minorities). The impact of these trainings on provider stigma was assessed.

**Methods:** A cohort of 300 MSB doctors, paramedics/nurses, and counselors were recruited, given a self-administered questionnaire measuring stigmatizing attitudes towards young populations at risk, and attended a two-day HIV and SRHR training (including a 90-minute session on gender and stigma issues). Six months later, the cohort repeated the survey and participated in a one-day supplemental training on stigma. The additional training was designed to encourage reflection on personal values, and to identify possible manifestations and negative impacts of stigma. A third survey was administered 4-6 months later. Additionally, a cross-sectional survey of MSB/Link Up clients age 15-24 was implemented before and after the second stigma training to assess client satisfaction.

**Results:** Stigma among MSB providers decreased significantly after both the initial HIV/SRHR training and after the supplementary stigma training. This included reductions in provider agreement that people living with HIV should be ashamed of themselves (35.3% to 19.7% to 16.3%; p< 0.001, Cochrane's Q test). Substantial reductions were also observed in providers who agreed that at-risk young people engage in "immoral behavior"—including sexually active young people (50.3% to 36.0% to 21.7%; p<0.001) and men who have sex with men (49.3% to 38.0% to 24.0%, p< 0.001). Young clients reported improvement in overall satisfaction with services after the second stigma training (67.8% to 97.8%; p< 0.001, Pearson's chi-square test).

**Conclusions:** Provision of a more intensive, supplementary stigma reduction training to MSB health providers resulted in significantly reduced stigmatizing attitudes towards young people affected by HIV. It is recommended that this training approach be scaled up substantially in Bangladesh.

## TUPED440

### MOVING TOWARDS A STIGMA-FREE LOUISIANA: A HOLISTIC APPROACH TO ADDRESSING LAYERED STIGMA AND DISCRIMINATION TO ENHANCE ACCESS TO HIV/STI SERVICES IN THE SOUTHERN UNITED STATES

R. Brewer[1], C. Daunis[1], S. Mukherjee[1], S. Chrestman[1], G. Brown[2], M. Smith[3], D. Ferrell[4], G. Payne[5], M. Theberge[6], J. Holmes[7], K. Perry[8], N. Fanwick[9], M. Wright[10], D. Wendell[10]

*[1]Louisiana Public Health Institute, New Orleans, United States, [2]New Orleans Regional AIDS Planning Council, New Orleans, United States, [3]HIV/AIDS Alliance for Region 2 (HAART), Baton Rouge, United States, [4]Priority Health Care, Marrero, United States, [5]Capitol Area Reentry Program (CARP), Baton Rouge, United States, [6]Greater New Orleans Fair Housing Action Center, New Orleans, United States, [7]AIDSLaw, New Orleans, United States, [8]Southern University, Department of Sociology, Baton Rouge, United States, [9]NO/AIDS Taskforce, New Orleans, United States, [10]Louisiana Office of Public Health, STD/HIV Program, New Orleans, United States*

*Presenting author email: rbrewer@lphi.org*

**Background:** In 2014, the Louisiana Public Health Institute in collaboration with 13 agencies from diverse sectors was funded by the U.S. Office of Minority Health to enhance access to HIV/STI services for young Black men living with and at risk for HIV infection; strengthen collaboration and referral systems among agencies; and address the social and economic barriers to services.

**Description:** As a result of Louisiana's high HIV/AIDS and social indicators (e.g., stigma, incarceration, and homelessness), this initiative in New Orleans and Baton Rouge:

1) provides care coordination and job supportive services for criminal justice involved Black men,

2) convenes Historical Black Colleges and Universities (HBCUs) in Louisiana to promote HIV awareness and stigma reduction efforts on college campuses;

3) conducts mystery shopping with housing providers to document housing discrimination experienced by young Black men;

4) implements anti-discrimination trainings with large employers; and

5) engages people living with HIV infection to lead and implement the HIV Stigma Index Project.

**Lessons learned:** Qualitative results revealed that the development of two integrated centers (one in New Orleans and Baton Rouge) consisting of 13 agencies has increased coordination and collaboration among partners to address the needs and barriers of young Black men. Initiative partners have developed formal relationships with employers to increase the number of Black men that are gainfully employed over time. It is important to conduct follow-up with young Black men in order to identify changing needs and barriers to services over time. The HIV Stigma Index project has built ownership and research capacity of PLWH to develop local approaches and solutions to HIV stigma and discrimination.

**Conclusions/Next steps:** Funding has been secured to connect the Orleans Parish Prison with the Greater New Orleans Health Information Exchange in order to enhance coordination and quality of care provided for former prisoners. Three hundred PLWH will be interviewed as part of the HIV Stigma Index Project to document their personal experiences of stigma and discrimination. The results will be used to develop local action plans. Mystery shopping with housing providers and convening of HBCUs will be conducted in 2016.

## TUPED441

### AN HIV STIGMA REDUCTION INTERVENTION FOR AFRICAN AMERICAN WOMEN: PRELIMINARY RESULTS FROM THE UNITY WORKSHOP TRIAL

D. Rao[1], D. Huh[1], S.E. Cohn[2], J. Turan[3], K. McCotter[4], M. Mugavero[3], J. Simoni[1]

*[1]University of Washington, Seattle, United States, [2]Northwestern University, Chicago, United States, [3]University of Alabama Birmingham, Birmingham, United States, [4]Ruth M. Rothstein CORE Center, Chicago, United States*

*Presenting author email: deeparao@uw.edu*

**Background:** AIDS has been a leading cause of death for African American women between the ages of 25 and 34 for the last 10 years. Stigma, reported at high levels among African Americans, can undermine optimal engagement in care, which is essential to reducing AIDS mortality.

**Methods:** In this first randomized controlled trial of an HIV stigma reduction intervention, the UNITY workshop, we examined stigma reduction among 239 African American women with HIV in Chicago and Birmingham before and after participation in one of two peer support group interventions: the UNITY workshop or a breast cancer awareness program (time-attention control). We examined change in stigma scores using the 14-item Stigma Scale for Chronic Illness for women in the two arms from baseline to (a) immediate and (b) 4 months post-treatment using mixed effects regression models. We also analyzed whether socio-demographic (age, education, years living with HIV) and mental health variables [alcohol use, posttraumatic stress symptoms (PSS), depressive symptoms] moderated the effect of treatment.

**Results:** Preliminary analyses of the 174 participants, who thus far completed a follow-up assessment, indicated a trend towards reduction in stigma scores from baseline to immediate post-treatment (*Estimate*=-1.2, *SE*=0.65, *p*=.06) that was maintained at 4-month post-treatment across both arms. There was greater post-treatment reduction in stigma scores in the UNITY group (-1.6 vs -0.5 points; not statistically significant). Examination of socio-demographic and mental health variables showed that PSS scores moderated this finding, and this effect was statistically significant. Women with higher PSS scores had greater reductions in stigma scores in UNITY compared to the breast cancer intervention immediately post-treatment (*Estimate*=-7.2, *SE*=2.9, *p*=.01).

**Conclusions:** Thus far, our results suggest promise for peer support interventions, such as the UNITY workshop, for African American women with HIV. Our preliminary findings suggest that post-traumatic stress symptoms may play an important role in whether or not African American women with HIV benefit from this peer support approach. A total of 239 women will complete follow-up assessments and 'booster' workshops, and further analyses of these data will contribute to our understanding of the potential benefits of this stigma-reduction intervention.

## TUPED442

### ADDRESSING THE INTERSECTIONAL ISSUES OF HIV AND AIDS THROUGH CAPACITY DEVELOPMENT OF ACADEMICS AND CURRICULUM

M. Pillay[1], P. Brouard[2]

*[1]Universities South Africa, Higher Education and Training HIV/AIDS Programme, Pretoria, South Africa, [2]University of Pretoria, Centre for the Study of AIDS and Gender, Pretoria, South Africa*

*Presenting author email: managa@universitiessa.ac.za*

**Background:** The Higher Education and Training HIV and AIDS (HEAIDS) is the flagship HIV prevention programme of South Africa's National Department of Higher Education and Training (DHET)**.** In aligning the programmes activities to the United Nations sustainable development goal number 16, HEAIDS received support from the country's National Skills Fund to develop the capacity of academics to use the higher education curricular to address social and development issues of the country.

**Description:** Twenty universities across the country received direct grants, to address capacity needs of academics. An analysis of their needs resulted in the development of 5 thematic areas which have been developed into capacity development workshops that are being facilitated across the universities. The Critical Diversity Literacy work implemented addressed the intersectional issues of HIV and AIDS.

**Lessons learned:** The Critical Diversity Literacy tool uses 8 analytical criteria to evaluate the presence of critical diversity literacy in any given social context. The workshop created a safe space to explore race, class, power and privilege thus addressing the many intersectional issues that pervade the HIV and AIDS and its persistence in society. Outcomes indicated that there were clearly psycho-social dimensions of the disease evident especially in the South African context. Participants were encouraged to confront their own biases and prejudices and develop an awareness of the role that that may play in perpetuating the challenges that we experience with respect to stigma and discrimination. In this particular context, academics are enabled to explore how their attitudes, perceptions and behavior may influence their teaching. This awareness is encouraged within the transformation agenda. While HIV and AIDS is the entry point, the workshop created a conduit to speak to the broader social justice issues.

**Conclusions/Next steps:** Providing academics with the tools to confront their own realities, biases and prejudices has proven to be a critical entry to defining the role that academics and exploring the agency of academics to use their curricular as a transformative tool in enabling their students to begin to shape and change the society that they live in and become better prepared to take their place as responsible and responsive citizens.

## TUPED443

### FEASIBILITY, ACCEPTABILITY, PRELIMINARY EFFICACY OF A STIGMA MANAGEMENT INTERVENTION FOR SPANISH-SPEAKING HIV-POSITIVE GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN

C.E. Rodriguez-Diaz[1], E.J. Ortiz-Sanchez[2], R.L. Vargas-Molina[2], G.G. Jovet-Toledo[2], V.C. Gonzalez-Seda[2], E.I. Santiago-Rodriguez[1]
*[1]University of Puerto Rico-Medical Sciences Campus, School of Public Health, Social Sciences Department, San Juan, Puerto Rico, [2]University of Puerto Rico-Medical Sciences Campus, School of Public Health, Center for Sociomedical Research and Evaluation, San Juan, Puerto Rico*
*Presenting author email: carlos.rodriguez64@upr.edu*

**Background:** Globally, gay, bisexual, and other men who have sex with men (MSM) remain disproportionally affected by the HIV/AIDS epidemic. In Puerto Rico (PR), a third of all men with HIV are MSM and HIV incidence in this group has increased 126% since 2002. MSM are among the least likely to engage in HIV-related services, mostly due to the multiple types of stigma and discrimination experiences they are subjected to because of their sexual minority and HIV-status. Despite the evidence of the negative impact stigma has on populations affected by HIV/AIDS, limited attention has been placed to the development of interventions that address it. In this presentation we will discuss findings from the implementation of a stigma management intervention targeted to HIV+MSM.
**Methods:** *Contacto*, a six-week individual intervention targeted to Spanish-speaking HIV+MSM in PR, consists of three encounters with a health educator using motivational interviewing techniques. The intervention supports participants' management of the negative impact of stigma related to HIV-status and sexual orientation/identity, and was developed using a convergent parallel mixed methods research design. Data for feasibility was collected through the resources and materials needed for the intervention, data about recruitment and retention rates informed acceptability, and preliminary efficacy was tested using a pre-post assessment. Analyses were completed using SPSS v.22.
**Results:** 98 participants' charts were created and included materials used during the intervention (tools to assess readiness to take action, educational materials, worksheets for plan development, etc.). Of all participants approached, 56.2% were recruited. All of the participants have attended to at least one encounter with the health educator. Participants' retention rate is 96.2%. In preliminary efficacy assessment, lower levels of HIV-felt stigma ($p$-value< 0.001), gay stigma ($p$-value< 0.001) and internalized homophobia ($p$-value=0.002) were reported.
**Conclusions:** The pilot assessment of this intervention targeted to HIV+MSM evidences the feasibility of fostering skills to manage the impact of the interconnections of multiple sources of stigma, while building resilience to disclose HIV status and engage in care. The development of interventions to reduce the impact of stigma among diverse groups must consider the cultural context where implemented.

## TUPED444

### WHAT WORKS TO PREVENT AND RESPOND TO VIOLENCE FOR FEMALE SEX WORKERS (FSW), MEN WHO HAVE SEX WITH MEN (MSM) AND PEOPLE WHO INJECT DRUGS (PWID): A SYSTEMATIC REVIEW

M. Decker[1], C. Lyons[1], G. Fouda[2], I. Njindam[1,2], S. Kurani[1], J. Hatcher[1], S. Baral[1]
*[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]CARE Cameroon, Yaounde, Cameroon*
*Presenting author email: mdecker@jhu.edu*

**Background:** Structural factors contextualize individual-level risks for HIV acquisition and transmission; especially within key populations. Despite their distinctions, key populations including MSM, FSW and PWID share social harms including criminalization and marginalization of occupation, sexual identity, and practices; together these factors hinder the coverage and uptake of effective HIV prevention and treatment responses. The need to prevent and respond to violence as a component of an effective HIV response is clear, though less is known about the content of these interventions.
**Methods:** We systematically reviewed the literature characterizing violence-related interventions for MSM, FSW or PWID across the three components of a comprehensive GBV response, including prevention, protection such as survivor support and services, and accountability such as legal and policy action. A comprehensive and systematic search protocol was iteratively developed including databases for both peer-reviewed and non-peer-reviewed reports. Our objectives were to characterize violence interventions, the level(s) at which they were implemented, and the quality of evidence of their success.
**Results:** Of 2980 (770 MSM, 1461 FSW, 749 PWID) peer-reviewed articles and 1040 (301 MSM, 476 FSW, 263 PWID) reports identified, 40 (15 MSM, 19 FSW, 11 PWID, not mutually exclusive) met inclusion criteria, representing 14 countries. Structural level interventions including safe environments for PWID and FSWs, and policy changes for MSM, enhanced safety. An integrated intervention for FSWs blending empowerment and police training improved safety and reduced violence. Individual level interventions included violence screening for MSM, and targeted violence response services for MSM and FSWs; where evaluated, rapid response mechanisms increased case reporting. Violence-related safety promotion and risk reduction counseling for FSWs reduced violence in some settings but not others. Quantitative evaluations were limited (18 total; 5 MSM, 9 FSW, 6 PWID).
**Conclusions:** Violence prevention and response interventions for MSM, FSWs and PWIDs span individual, community and structural levels, with qualitative evidence of promising practices at each level. Rigorous quantitative evaluations are limited. Implementation research approaches represent a potential methodology to facilitate the rigorous evaluations needed of promising practices to facilitate scale and assess improvements in HIV prevention, treatment, and human rights outcomes when adequate scaled.

## TUPED445

### A PARTICIPATORY THEATRE INTERVENTION PILOT STUDY TO REDUCE STIGMA TOWARDS LESBIAN, GAY, BISEXUAL AND TRANSGENDER (LGBT) PEOPLE IN SWAZILAND AND LESOTHO

C. Logie[1], R.K. MacKenzie[2], L. Dias[2], J. Jenkinson[2], V. Madau[3], S. Sibiya[3], A. Ranotsi[4], T. Mothopeng[5], W. Nhlengethwa[6], S. Baral[7], P.A. Newman[1]
*[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, ON, Canada, [2]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [3]Rock of Hope, Manzini, Swaziland, [4]Maluti School of Nursing, Maluti, Lesotho, [5]Matrix Support Services, Maseru, Lesotho, [6]Southern Africa Nazarene University, Manzini, Swaziland, [7]Johns Hopkins University, Baltimore, United States*
*Presenting author email: jesse.jenkinson@gmail.com*

**Background:** Stigma and discrimination targeting lesbian, gay, bisexual and transgender (LGBT) people compromise health and human rights. It is critical to address LGBT stigma in Swaziland and Lesotho, the countries with the highest HIV rates in the world. Scant research has explored effective strategies to reduce LGBT stigma in Southern Africa. We developed and pilot-tested a participatory theatre intervention to reduce stigma towards LGBT people in Swaziland and Lesotho.
**Methods:** This was a multi-centre pilot study. We conducted in-depth interviews with LGBT people (Swaziland: n=50; Lesotho: n=50) to enhance understanding of LGBT stigma. Local LGBT and theatre groups worked with this data to create 3 short skits to demonstrate stigma experienced by LGBT persons in healthcare, family, and community settings. We used purposive sampling to recruit nursing students, community members, healthcare providers, and educators in Swaziland and Lesotho as participants. Participants conducted a pre-test (Time 1) followed by a 2-hour participatory theatre intervention. Directly following the intervention participants conducted a post-test (Time 2), and participated in a focus group to explore reactions to the participatory theatre. Participants completed a survey 6 weeks post-intervention (Time 3). Mixed-effects regression was conducted to determine changes in LGBT stigma between the time points.
**Results:** There were no significant differences in LGBT stigma between Lesotho participants (n=57) (mean age: 27.7, SD: 9.5; gender: men 35%, women 65%) and Swazi participants (n=49) (mean age: 26.7, SD: 6.5; gender: men 40%, women: 60%) at pre/post intervention so findings are combined across sites. LGBT stigma from Time 1 to Time 2 decreased 5.7% (95% CI: -9.2, -2.2; p< 0.01). The mean score change from Time 1 to Time 3 was 5.6% (95% CI -11.9, 0.7, p=0.08). Focus group participants discussed increased understanding of: LGBT stigma and discrimination; sexual and gender diversity; and increased self-knowledge of personal biases.
**Conclusions:** Findings reveal initial decreases in LGBT stigma following a participatory theatre intervention in Swaziland and Lesotho. Changes were not sustained at 6-week follow up, however, highlighting the need for booster sessions or alternative approaches to reinforce anti-stigma messaging. Qualitative findings suggest that participatory theatre holds promise in promoting understanding and self-reflexivity regarding LGBT issues.

## Traditional and complementary approaches

### TUPED446

#### Beyond the workplace: upscaling through supply chain and mentorship

E. Maziofa-Tapfuma[1], J. Viner[2]
[1]*Swedish Workplace HIV/AIDS Programme, HIV/AIDS, Harare, Zimbabwe,* [2]*Swedish Workplace HIV/AIDS Programme, HIV/AIDS, Stockholm, Sweden*
*Presenting author email: edith@swhap.org*

**Background:** The Swedish Workplace HIV/AIDS Programme (SWHAP) is a joint initiative by International Council of Swedish Industries (NIR) and Swedish industrial and Metal Workers' Union (IF Metall) and funded by Swedish International Development Agency (SIDA). The Program primarily targeted Swedish linked companies. The program is currently implemented in 10 countries in East and Southern Africa. 365 workplaces in 127 companies in 10 countries with 32 000 employees running workplace proms with average of 69% HTS uptake among partners.
**Description:** The current partners have developed extensive capacity and expertise in developing, implementing and managing their workplace programs. The next step was to extend the program to contractors and suppliers - Supply chain with HIV/AIDS workplace programs and mentor neighboring companies to have the same.
The main objective of the program was to develop the capacity to fight HIV/AIDS in the Swedish companies' supply chain, Minimize the risk to which Supply Chain company's and Swedish companies are exposed to in respect of HIV/AIDS in the workplace, Maintain the Swedish company's supply chain, Demonstrate leadership in the Southern Africa region in managing HIV/AIDS, Develop international quality practice on how the private sector responds to HIV/AIDS.
The role played by the mentor company was to take the lead role in the implementation of the programme. The mentor companies were responsible for coordination, logistics, training, monitoring and evaluation and continuously liaised with by service providers to support HTS.
**Lessons learned:** To date the SWHAP programme has supported 50 companies at 57 work sites and have reached 15 114 workers with HIV/AIDS information, developed policies, built capacity among P.Es and committees and conducted HTS.
1. The program has succeeded in minimizing HIV risk among the Swedish Companies Supply Chain .
2. Demonstrated leadership at national levels in private sector workplace program development.
3. mentorship process a progressive and innovative way to cascade learning's from workplaces and spread best practices.
**Conclusions/Next steps:**
- Supply chain programs have proved their impact and are very successful based best practice from the mentor company
- Replication of model to more companies
- Recommend to other development partners to take up similar initiatives.

### TUPED447

#### Complementary and integrative health (CIH) use in older adults with HIV

K. Porter[1,2], M. Brennan-Ing[2]
[1]*MPA Media, Acupuncture Today, Santa Anna, United States,* [2]*ACRIA, Center on HIV and Aging, New York City, United States*
*Presenting author email: kristen.e.porter@hotmail.com*

**Background:** People living with HIV report higher CIH utilization than the general population but little is known about CIH use in older adults with HIV (OAWH). This study examines differences between OAHW CIH users and non-users, and examines if CIH use mediates the relationship between HIV-stigma and psychological well-being (PWB).
**Methods:** We used data from the Research on Older Adults with HIV study (ROAH; N = 914), which recruited HIV-positive participants aged 50 and older via New York City organizations in 2005 using a non-probability purposive sampling technique. PWB was assessed with Ryff's six dimensional measure (1989), stigma with the HIV Stigma Scale (Berger et al., 2001), and CIH use was self-reported. Data were analyzed for group differences using *t*-tests and chi-square analyses. Structural equation modeling (SEM) was used for mediation analysis.
**Results:** The ROAH sample was 71% male, the mean age was 55.5 years, 87% were racial/ethnic minorities and 34% were sexual minorities. Twenty-nine percent were using CIH, with body based methods (e.g., chiropractic) most frequent (14%), followed by alternative medical systems (e.g., acupuncture; 13%), biologically-based therapies (e.g., herbs; 12%), mind-body interventions (e.g., meditation; 6%), and energy therapies (e.g., reiki; 2%). CIH users were significantly more likely to have an AIDS diagnosis, be working, and identify as a sexual minority than non-CIH users. The SEM model showed a good fit; RMSEA=.058, 95% CI [.053, .063]. CIH use was positively associated with PWB (β = .09) and partially mediated the association between HIV-stigma and PWB. The negative relationship between HIV-stigma and CIH use was significant only for sexual minorities (β = -.18), while the positive effect of CIH use on PWB was significant only for heterosexuals (β = .12).
**Conclusions:** Finding that CIH use is associated with better PWB highlights the salience of developing and examining CIH interventions for OAWH. Given the negative association of HIV-stigma on CIH use in sexual minorities, ASOs are encouraged to provide CIH to mitigate the HIV-stigma clients may perceive outside ASOs. CIH providers can extend their outreach to OAWH by proving welcoming messages to counteract HIV-stigma such as including "HIV" in the list of conditions treated.

### TUPED448

#### The role of indigenous knowledge in HIV communication, prevention, treatment, care and support in Malawi

B. Matatiyo[1], D. Kalomba[2], C. Mablekisi[1], C. Teleka[3], A. Muula[4]
[1]*National AIDS Commission, Planning Monitoring Evaluation and Research, Lilongwe, Malawi,* [2]*National AIDS Commission, Lilongwe, Malawi,* [3]*National AIDS Commission, Behaviour Change Interventions, Lilongwe, Malawi,* [4]*College of Medicine, Medicine, Blantyre, Malawi*
*Presenting author email: cteleka2009@yahoo.com*

**Background:** Indigenous knowledge (IK) is the basis for local-level decision making to solve local problems. In Malawi experience has shown that behavior change interventions, based on models of diffusion of knowledge, change and innovation using participatory approaches and common impersonal media have not been fully effective. A study was therefore conducted to assess the role of IK in HIV prevention, treatment, care and support.
**Methods:** This was a cross-sectional and qualitative study comprising in-depth and key informant interviews as well as focus group discussions. Data were collected in ten main cultural sites of Malawi including two suburban cultures from two major cities, Lilongwe and Blantyre. The secondary data collection was done through desk reviews of literature. The research focused on two major areas: Role of IK in
(a) HIV prevention, treatment, care and support; and
(b) Communication strategies.
**Results:** 98% of respondents accept that IK can play a role in HIV prevention. The study shows that 53% (78 of 146) maintain that respect for parents' and elders' counsel is primary in HIV prevention. In order to implement IK for HIV prevention there is need to manage westernization and modernization and eradicate negative behavioral patterns. A majority (101 of 146) of respondents identified one to one education and counselling as appropriate media and channels for communicating IK. Most people (121 of 146) believe herbs can be used to treat AIDS particularly boosting the immune system.
**Conclusions:** In order to implement IK for prevention, treatment, care and support there is need to manage westernization and modernization. There is also need to manage stigmatization of those who want to live by positive IK. To implement IK for HIV treatment a number of challenges need to be resolved. These include scarcity and cost of local herbs, religious beliefs and traditions, belief in modern medicine, stigmatization and denial among others.

## Voluntary counselling and testing programmes and other approaches to HIV testing such as community-based testing and self-testing

### TUPEE449

#### Investigating feasibility and acceptability of a rapid HIV self-testing device in adolescents and young adults

P. Smith, M. Wallace, L.-G. Bekker
*The Desmond Tutu HIV Centre, Institute for Infectious Disease and Molecular Medicine, Faculty of Health Science, University of Cape Town, Cape Town, South Africa*
*Presenting author email: philip.smith@hiv-research.org.za*

**Background:** While HIV counseling and testing (HCT) are traditionally available from clinics and day hospitals in South Africa, most adolescents do access these and do not know their status. Adding HIV self-testing to the option menu may afford an opportunity to test for those who would otherwise delay testing. The objective of the current study was to investigate the usability and acceptability of an HIV rapid self-testing device in adolescents and young adults (16-25) at the Desmond Tutu HIV Foundation Youth Centre and Mobile Clinic.

**Methods:** Self-presenting adolescents and young adults were invited to participate in the study investigating the fidelity, usability and acceptability of the AtomoRapid HIV Rapid self-testing device. During the study 224 participants enrolled, where 155 (69,2%) were female. A healthcare professional demonstrated use of the device to participants. Participants then completed the self-test in the presence of the healthcare professional who rated the participants' accuracy of using the device. After completing the HIV self-test, participants rated the acceptability and usability of using the HIV rapid self-testing kit.
**Results:** Overall, fidelity was high; 216 (96,4%) participants correctly completed the test and read and interpreted the HIV test result. There were eight (3,6%) user errors; six participants failed to prick their finger even though the lancet fired correctly. These participants correctly completed the test and read their results correctly on a second attempt. There were two user errors where participants failed to use the device correctly by breaking the device capillary tube and not filling the capillary tube. Participants rated acceptability and usability highly, with debut testers giving significantly higher ratings for both. Younger participants gave significantly higher ratings of acceptability.
**Conclusions:** The results of this study show that HIV self-testing with the AtomoRapid device was highly acceptable and that adolescents and young people can accurately use the device. Further research may investigate how much further support is needed to ensure that self-testing is undertaken safely.

## TUPEE450

### SCALING UP STANDARDS, TESTING AND LINKAGE TO CARE: IMPLEMENTATION OF A PORTUGUESE COMMUNITY-BASED SCREENING NETWORK

D.A. Simões[1], R. Freitas[1], L.M. Rocha[2], A. Curado[3], D. Silva[3], J. Rojas[2], A. Aguiar[4], P. Meireles[4], H. Barros[4]
*[1]GAT - Grupo de Ativistas em Tratamentos, Project Management, Lisbon, Portugal, [2]GAT - Grupo de Ativistas em Tratamentos, CheckpointLx, Lisbon, Portugal, [3]GAT - Grupo de Ativistas em Tratamentos, In-Mouraria, Lisbon, Portugal, [4]Institute of Public Health, University of Porto, EPIUnit, Porto, Portugal*
*Presenting author email: daniel.simoes@gatportugal.org*

**Background:** Portugal has 60-65.000 people living with HIV, 20-25.000 are undiagnosed. Every year over 1.000 people are newly diagnosed with HIV and late presentation is very frequent (49,1% in 2014), making it one of the most expressive epidemics in Western Europe. Validity of the national surveillance data on Hepatitis has never been evaluated. Since 2011, NGO GAT provides tailored community-based counselling, testing and linkage to care in Portugal for HIV priority groups and, since 2012, engaged in a joint action with other community based structures to promote access to prevention, scale-up testing and to gather surveillance data for advocacy and funding. Neither national recommendations nor surveillance systems are established to monitor prevention, testing and linkage to care outside formal health structures.
**Methods:** Since May 2015, GAT is promoting the creation of a Community-based Screening Network, according to ECDC, UNAIDS and WHO recommendations, that enabled cooperative training, centralised laboratory supervision (partnership with São João Hospital Centre), integrated HIV, HBV, HCV and syphilis screenings roll-out and national open prospective cohort implementation (partnership with Institute of Public Health of the University of Porto).
**Results:** Since August 2015, 13 organizations were incorporated, totalling 24 testing points (including 7 mobile units). Over 65 people received training to offer and perform all 4 tests and collect surveillance indicators. During 2015 (pre and post network), 9786 HIV tests (206 reactive), 1962 HBV (37 reactive), 2467 HCV (71 reactive) and 4538 syphilis tests (168 reactive) were performed. Of the viral hepatitis and syphilis reactive results, 234 (84,8%) were HIV negative. From October to January 2015, 665 users of these community based testing services accepted to be enrolled in the cohort.
**Conclusions:** Integrated offer of the four tests allows for the identification of otherwise lost diagnostic opportunities, and thus should be made available whenever possible to maximize efficiency of screening programs. Articulation between Community, Academia and Public Health sectors offers the opportunity for the development of innovative solutions, both in terms of service delivery and in terms of surveillance systems. Lastly, community based testing continues to show its efficiency in reaching key groups and in finding undiagnosed infections.

## TUPEE451

### REACHING THE FIRST 90: INDEX CASE HIV TESTING AND THE ROLE OF A COMMUNITY MODEL OF CARE IN TETE, MOZAMBIQUE

E. Simons[1], T. Ellman[2], R. Giuliani[3], C. Bimansha[1], C. das Dores T.P. Mosse Lázaro[4], A. Albano[4]
*[1]Médecins Sans Frontières, Tete, Mozambique, [2]Médecins Sans Frontières, Southern Africa Medical Unit, Capetown, South Africa, [3]Médecins Sans Frontières, Maputo, Mozambique, [4]Provincial Health Department, Tete, Mozambique*
*Presenting author email: tom.ellman@joburg.msf.org*

**Background:** Community-based HIV testing and counseling (HTC) is an essential WHO-recommended complement to facility-based testing. Médecins Sans Frontières and the Mozambican Ministry of Health in Tete introduced Community ART groups (CAGs), a community-based strategy to simplify ART access, in 2008. Since 2012, the CAGs potential to promote community testing through an index case strategy and linkage to care has been explored at the community-level. This analysis describes the outcomes of this approach.
**Methods:** Retrospective analysis of routinely collected data included persons tested in the community between July 2012 and December 2014. Positivity rate was stratified by age, sex and testing referral method: immediate CAG family member (spouse, sibling, child or parent), other CAG contact (non-immediate family member or neighbor), other referral (community leader, community health worker or activist referral) or self-referral.
**Results:** The analysis included 16,750 persons tested in the community; 61% were female and the median age of individuals was 20 [13-34]. HIV positivity of 5% was observed. Positivity dropped from 19% (69/355) in 2012 to 4% (418/11116) in 2014. The proportion of tests carried out on CAG family members decreased from 13% in 2013 to 6% in 2014.
Immediate CAGs family members had higher HIV-positivity rates (9%) compared to other CAG contacts (4%); among non- CAGs contacts, self-referrals had a higher positivity rate (8%) compared to other linkage to testing methods (4%).
Among youth (15-24), positivity was higher in females (4%) than males (2%). Among adults >25 years, positivity was higher among males (8%) than females (6%). 2% of children < 15 years tested positive overall; 4% among immediate CAG family contacts, 1% among other CAG contacts, 1% among other referrals and 3% among self-referrals.
**Conclusions:** Community-based HTC activities increased testing among populations who typically do not utilize health services. The strategy identifying relatives of CAG contacts and self-referrals is a simple way to identify a high-risk population, though saturation was reached relatively quickly. Further investigation of strategies promoting testing via CAGs and other groups of PLHA at community level is essential to increase the yield of community testing, HCT coverage, and linkage to care.

## TUPEE452

### SCALING UP HIV TESTING AND COUNSELLING AMONG INDIGENOUS RURAL DWELLERS USING VOLUNTEERS AS TESTERS AND COUNSELLORS: THE CASE OF HAF MOBILE HTC PROJECT IN EKITI STATE, NIGERIA

C. Doherty[1], R. Ajayi[2], Y. Ajumobi[3]
*[1]Ekiti State AIDS Control Agency, Project Management, Ado-Ekiti, Nigeria, [2]Ekiti State AIDS Control Agency, Community Mobilization Unit, Ado-Ekiti, Nigeria, [3]Ekiti State AIDS Control Agency, M and E Unit, Ado-Ekiti, Nigeria*
*Presenting author email: dcolusegun@yahoo.com*

**Background:** HIV testing and counselling (HTC) is the entry point into care, treatment and support for persons in need. Getting the needed human resource to support scaling -up remains a major challenge in Ekiti State. In 2013, in response to the HTC service gap, Ekiti State HIV program development project II through the fund from World Bank supported local government authority to rapidly scale up innovative approaches in HTC targeting the rural people.
**Methods:** The program was designed to compliment facility based HTC and to support Local Authorities to take HIV services to the door steps of rural dwellers using multivariate approach. The program was implemented in 16 local government Authorities in 43 rural communities using trained lay counsellors for mobile and house-to-house HTC between years 2013-2015. The team keyed into various socio-cultural events such as festivals, religious, Village square meetings and traditional ceremonies in the project communities to mobilize and increase access of the community members to HTC during the project period. Community outreach teams involving community head and opinion leaders were put in place to ensure the coordination and quality control of service delivered. Liquid hand wash elements and biohazard bags were used to ensure safety precautions. Lay counsellors and testers deployed paper-based HTC data, which later filled into a project electronic database to capture specifically the coverage and frequency of community based HTC services delivery for analysis using SPSS 2.0 soft ware.

**Results:** The project provided HTC service to 309,123 individual (123,859 males, 185,123 females) increasing rural HTC target by 43%. The project contributed to about 23% of individual in the state who knows their HIV status. A total of 547 advocacy visits were conducted, 394,165 (384,339 male, 9,756 females) individual were reached with condom program. 1,950 individuals links and enrolled into care including 352 pregnant women enrolled into PMTCT. A total number 2004 reactive cases were referred for care and treatment.
**Conclusions:** Community participation in HTC planning, implementation and monitoring promote access to HIV services. HIV programmes that offer community-based HTC with good referral system, as a link to care will compliment facility-based HTC.

## TUPEE453

### COMMUNITY-BASED RAPID HIV TESTING FOR KEY POPULATIONS IN BRAZIL: WHO ARE WE REACHING?

T. Lobo[1], C.D.B. Habckost[1], M. Sabidó[2], A.R.P. Pascom[1], F.C. Mesquita[1]
*[1]Ministério da Saúde, DST, Aids e Hepatites Virais, Brasília, Brazil, [2]Fundação de Medicina Tropical, Manaus, Brazil*
*Presenting author email: tainah.lobo@aids.gov.br*

**Background:** Brazil's HIV epidemic is largely concentrated among key populations whose HIV infection rates can be up to 20 times higher than those observed in the general population. Rapid HIV testing and counselling in community settings, delivered by trained lay peers, allows for easier access to HIV testing. Our goal was to present the percentage of positive HIV rapid tests and of first-time testers within the key populations targeted by the 'Live Better Knowing' programme, a nationwide initiative launched by the Brazilian Ministry of Health in close collaboration with NGOs.
**Methods:** Between January 2014 and April 2015, 53 Brazilian NGOs administrated rapid oral fluid HIV tests (DPP HIV-1/2 Bio-Manguinhos/Fiocruz) to sex workers (SW), men who have sex with men (MSM), transgender people and people who use drugs. HIV testing was offered in public places where these key populations commonly meet. Participants were interviewed by means of a brief questionnaire containing sociodemographic data and high-risk behavior for HIV.
**Results:** In total, 29,713 participants were tested; 46.8% of them had never been tested before (approximately 60% among people who use drugs [PUD], 55% among MSM, and 50% among male SW). Prevalence of HIV positive results was 10.7% in transgender people; 4.7% in male SW; and 4.6% in MSM. Among transgender people who were also SW, the percentage of positive results was 13%; among those who were also DU, it was 5.3%. Among MSM who were also SW, this percentage was 8.1%.
**Conclusions:** Community-based rapid HIV testing delivered by peers reached key populations that had not previously accessed HIV testing. SW and DU were observed in all key populations tested within the project and, as such, must be treated as transversal. Furthermore, the high number of reactive tests and of people who had never before been tested highlight the need to further expand this strategy.

| Key population | % HIV reagent results | % Never tested for HIV |
|---|---|---|
| Transgender people | 10.7 (1,612) | 36.0 (1,596) |
| Male SW | 4.7 (1,051) | 49.4 (1,034) |
| MSM | 4.6 (5,364) | 55.4 (5,303) |
| PUD | 2.4 (4,215) | 59.6 (4,172) |
| Female SW | 1.5 (5,577) | 24.7 (5,531) |
| Other people who were at places where testing occurred | 1.2 (11,892) | 54.9 (11,760) |
| Total | 2.7 (29,711) | 46.8 (29,396) |

*[Table 1. Prevalence of HIV tests in lifetime, HIV reactive results and Odds Ratio for HIV reactive results by category]*

## TUPEE454

### EXPRESS TESTING SERVICE FOR GAY AND BISEXUAL MEN DOUBLES THE VOLUME AND FREQUENCY OF HIV TESTING FREQUENCY IN SYDNEY, AUSTRALIA: A COHORT STUDY

V. Knight[1,2], R. Guy[3], A. McNulty[4], H. Wand[3]
*[1]South East Sydney Local Health District, Sydney Sexual Health Centre, Sydney, Australia, [2]University of New South Wales Australia, The Kirby Institute, Sydney, Australia, [3]Australian University of New South Wales, The Kirby Institute, Sydney, Australia, [4]South East Local Health District, Sydney Sexual Health Centre, Sydney, Australia*
*Presenting author email: rguy@kirby.unsw.edu.au*

**Background:** HIV infection in gay and other men who have sex with men (MSM) is an international public health concern and increasing HIV testing frequency is an important prevention goal. We assessed the impact of introducing an express clinic at an existing large sexual health centre on tests done, infections detected and repeat HIV testing in MSM in Sydney, Australia. The express service enabled men to attend without appointment, self-complete risk information and self-collect samples.
**Methods:** We established a retrospective cohort of asymptomatic MSM attending the centre from 2011-2013. In the period when express was introduced we calculated the number of HIV/STI tests and infections detected in the express clinic, routine clinic and overall at the centre. As testing guidelines recommend high-risk men test every 3-6 months, we used bivariate and multivariate regression methods to assess the independent association between service type (xpress or routine), and repeat testing within 6-months in higher-risk MSM (>5 male partners in the preceding 3 months). Other co-variates included in the model included demographics and risk behaviours.
**Results:** The total number of HIV tests conducted in the 3-year study period was 14827 and 278 new HIV infections detected. Of these, 9121 HIV tests (62%) were conducted in the express clinic and 44 new infections were detected (0.48% positivity) (16% of all new HIV infections). Testing at the express clinic resulted in the centre increasing the total HIV tests done by over 2-fold; from 2908 in 2010 (year before Xpress was implemented) to 6470 in the final year of the express period. Among high-risk MSM, attending the express clinic was independently associated with retesting within 6 months of an initial test (adjusted OR (AOR)=2.59,95%CI:2.14-3.13, p< 0.001) compared to attending the routine clinic only.
**Conclusions:** In conclusion we found that introduction of an express testing service increased the capacity of the centre to offer substantially more HIV/STI testing, more infections were detected and higher-risk men were two-times more like to undergo HIV retesting. Optimising current services by introducing express testing services should be adopted more widely to help achieve public health goals of increasing HIV testing frequency and detection of infections.

## TUPEE455

### ACHIEVING UNAIDS FIRST 90: USER PREFERENCE'S FOR HIV TESTING IN UGANDA

S. Asiimwe[1,2], J.C. Wurst[3], S. Xiao[4], J. Oloya[4], C.C. Whalen[4]
*[1]Integrated Community Based Initiatives (ICOBI), Kabwohe-Itendero, Uganda, [2]Kabwohe Clinical Research Center (KCRC), Kabwwohe-Itendero, Uganda, [3]Terry College of Business University of Georgia, Marketing Department, Athens, United States, [4]College of Public Health University of Georgia, Epidemiology and Biostatistics, Athens, United States*
*Presenting author email: asiimwes@icobi.or.ug*

**Background:** Despite availability, many at risk of HIV cannot access prevention and care services due to low uptake of HIV Testing. Using trade-off (conjoint) analysis to inform relative preferences for the different modes of HIV testing, we estimated and simulated the probability of HIV test uptake in Uganda using stated preferences.
**Methods:** We surveyed 246 high-risk fisherfolk from western Uganda. We defined five important attributes of HIV tests and their levels (mode of HIV test and specimen collection method, location of HIV test service, price, availability of counseling services, timeliness and accuracy). A fractional factorial design was used to develop scenarios that consisted of combinations of attribute levels. Respondents were asked 10 questions about whether they would choose between 5 alternatives each, including 'none'. A multinomial conditional logit and hierarchical bayes model were used to estimate utilities for HIV testing attributes.
**Results:** Out of the 2,214 random choices presented, oral HIV self-testing using oral swab had the highest utility within the mode of testing attribute. A home-based location, no cost, talking to a counselor with access to immediate and accurate results all had the highest utility within attribute respectively. Importance in informing respondent preferences for HIV testing was highest with timeliness and accuracy (30.2%), price (29.7%) and counseling (17.5%) respectively. Compared to persons who had never tested, previous HIV testers had a higher mean attribute importance scores for mode of HIV test (12.1% vs. 10%, p=0.04) and test location (11.5% v. 9.1%, p=0.02) respectively. Mean attribute importance scores were no different by age, sex and income. Given no costs of service, a home-based HIV self-test had the

largest share of preference (24.5%), twice that of the rapid testing currently done at public clinics. The share of preference drops to 9.9% when a $2 fee is included.
**Conclusions:** HIV test timeliness and accuracy, price and counseling availability are key determinants of individual preferences for HIV testing in a high-risk community of fisherfolk in Uganda. An oral HIV self-test with highly accurate and immediate results offered at no fee with counseling support could increase HIV test uptake.

## TUPEE456

### PEER-BASED SERVICE DEVELOPMENT: A STRUCTURED AND TIMED EXPANSION OF COMMUNITY-BASED HIV TESTING FOR GAY MEN IN A HIGH-INCOME SETTING

J. Gray[1], K. Price[1], B. Clifton[1], J.T. Lockwood[2], A. McNulty[2,3], C.C. O'Connor[4,5,6], P. Read[5,7], P. Keen[5]
*[1]ACON Health, Sydney, Australia, [2]Sydney Sexual Health Centre, South Eastern Sydney Local Health District, Sydney, Australia, [3]School of Public Health and Community Medicine, UNSW Australia, Sydney, Australia, [4]Sexual Health Centre, Sydney Local Health District, Sydney, Australia, [5]The Kirby Institute for Infection and Immunity in Society, UNSW Australia, Sydney, Australia, [6]Central Clinical School, University of Sydney, Sydney, Australia, [7]Kirketon Road Centre, South Eastern Sydney Local Health District, Sydney, Australia*
*Presenting author email: jgray@acon.org.au*

**Background:** Rapid HIV tests have been licensed for diagnosis and/or screening at the point of care in most countries for many years, but were first licensed for this use in Australia only in December 2012. With historically high levels of testing through laboratory tests it took significant advocacy to facilitate their approval in Australia. This provided an opportunity to not just trial a 'new' technology, but to also develop models of service delivery that increase the testing options for gay and bisexual men in New South Wales (NSW), Australia.
**Description:** A new multidisciplinary testing service incorporating trained peer educators and sexual health nurses was first developed in partnership by ACON, NSW's leading community-based HIV and LGBTI health organisation, and Sydney Sexual Health Centre, the largest publically funded sexual health clinic in NSW. Trained peer educators perform rapid tests and provide results, explain STI specimen collection, while the nurse provides clinical supervision and collects venepuncture blood specimens for parallel HIV laboratory. Since mid-2013, capacity has increased from 12 appointments per week, to 241 per week across four sites.
**Lessons learned:** A staged expansion was essential to the success of the service in order to develop partnerships between the services and ensure that resources were used efficiently. Expansion to new sites was largely predicated on the existing services reaching capacity and the need to increase geographic coverage. The service has performed close to 10,000 tests with an HIV positivity rate of close to 1% and approximately 10% of clients have had at least one STI. Client feedback surveys with 374 clients have showed that 99% of clients liked peer-led testing and would return and recommend these services.
**Conclusions/Next steps:** A careful, staged expansion has allowed a community based rapid HIV testing service to go from being niche to one of the biggest HIV testing services for gay men in NSW in less than three years. The peer-based approach with the backing of clinical governance and expertise from specialist sexual health services has provided a popular and successful new service model, with 8% of gay men in a community survey reporting having used the service in 2015.

## TUPEE457

### WORKPLACE-BASED WELLNESS PROGRAMMES PROVIDE ACCESS TO A SAFE SPACE FOR HIV TESTING

S. Badul
*KwaZulu-Natal Provincial Administration, Office of the Premier, South Africa, South Africa*
*Presenting author email: sanoosha.badul@kznpremier.gov.za*

**Background:** The KwaZulu-Natal provincial government employs approximately 195 294 employees, 68% of whom are female. Given the high burden of HIV in the country and this province, the Department of Public Service and Administration introduced a workplace based HIV Counselling and Testing Campaign Nationally to encourage all employees to know their HIV status with flexibility on how each department implemented the campaign. One option that was utilized was the integration of HIV testing into a general wellness screening programme.
**Methods:** On-site workplace place health screening was offered to all employees from April 2012 to March 2015. Voluntary and confidential testing was conducted by nurses using standard procedures and documented on health screening forms. All employees who tested positive were either referred to the employee health and wellness practitioner or a health care provider. Uptake of services was compared over a 3 year period: April 2012 - March 2013, April 2013 - March 2014 and April 2014 - March 2015.
**Results:** Over the three year period, a total of 35 283 (18.1%) employees participated in the programme, 26.7% (9444) of whom were female. Overall, 13658 (38.7%) employees had an HIV test, 34740 (98.5%) had a cholesterol test, 34709 (98.4%) had a blood glucose test and 34336 (97.3%) had their blood pressure checked.
Uptake of HIV testing by females in 2012/12, 2013/4 and 2014/5 was 74.1%, 66.3% and 67.3% respectively in comparison to males was 25.9%, 33.7% and 32.6%. The total HIV prevalence increased from 3.9% in year 1, to 5.1% in year 2 to 5.8% in year 3. The HIV prevalence rates in men (5%, 4.8% and 3.9%) and women (6%, 5.1% and 3.8%) was similar.
**Conclusions:** On-site workplace testing provides a platform for employees to access services and manage their health and wellbeing by conducting regular health screening. Further research needs to be undertaken to understand why the uptake of HIV testing was so low compared to other chronic health conditions.

## TUPEE458

### KNOW IN ORDER TO ACT: TAKING HIV TESTING SERVICES TO VULNERABLE WORKERS

I. Chimedza[1], R. Mundingi[2], F. Munhuwei[3], R. Ameur[4], S. Mabhele[4]
*[1]International Labour Organization, ILOAIDS, Harare, Zimbabwe, [2]SAfAIDS, Harare, Zimbabwe, [3]ZAPSO, Harare, Zimbabwe, [4]International Labour Organization, Pretoria, South Africa*
*Presenting author email: chimedza@ilo.org*

**Background:** In Zimbabwe, only half of those living with HIV know their status. Women and men in precarious informal employment typically work long hours and are unable to leave their operations to access health services unless they fall sick. This is particularly the case for men, who generally have poor health-seeking behaviour.
**Description:** A partnership between the private sector, civil society, and national service providers - under the ILO's VCT@WORK campaign - took voluntary HIV testing and counselling services (VCT) to hard-to-reach workers, using a sectoral approach to encourage workers to know their HIV status. The targeted sectors were agriculture and small-scale mining operations, where many informal workers are employed. The focus of the 3-month campaign was on:
- small-holder sugar farming estates in Mkwasine;
- operators in the informal economy who run individual small enterprises at designated sites in Harare; and
- small-scale mining operators involved in open-cast gold mining in the Bubi district.

Mobilization was done through dissemination of IEC material and "edutainment", using music and sport. Group education provided information on the importance of knowing one's HIV status, and on the modes of HIV transmission, prevention and treatment. Post-test counselling was done individually based on results. Workers welcomed the mobile VCT services at their workplaces, as illustrated by increased uptake of services. The campaign reached 31,060 workers with HIV prevention messages. A total of 13,368 workers undertook HIV testing, and 844 workers who tested positive were referred for care and support services.
**Lessons learned:**
1. The "one-stop shop" concept integrating HIV testing services with other health services is an effective and efficient way to reach farming, mining, and other communities in the informal economy.
2. Health education on HIV prevention focusing on perceived vulnerabilities, risks and perceived benefits increases uptake of HIV testing services.

**Conclusions/Next steps:** The partnership will work to strengthen linkages between marginalised working populations and the public health system for the extension of regular health services. In particular, the partnership will focus on integrating HIV testing services (HTS) with sexual and reproductive health rights and anti-drug abuse programmes, particularly for vulnerable young workers and women.

### ADDRESSING HIV/HCV CO-INFECTION AMONG INJECTING DRUG USERS IN JAKARTA, INDONESIA, USING PEER-DRIVEN INTERVENTION

E. Agustian[1], C. Stoicescu[2], L. Pramitasari[3], S. Sugiharto[1]
*[1]Persaudaraan Korban Napza Indonesia, Jakarta Selatan, Indonesia, [2]Oxford University, Social Policy and Intervention, Oxford, United Kingdom, [3]Yayasan Rumah Singgah PEKA, Bogor, Indonesia*
*Presenting author email: edoagustian@gmail.com*

**Background:** Co-infection with HIV and HCV is common among injecting drug users and can lead to various negative health outcomes, including long-term illness and death. In the Indonesian context, programme data indicates that HIV/HCV co-infection rates among IDU may range from 60% to 90%. In the absence of national surveillance data on HCV and HIV co-infection and low HCV testing and treatment rates, the Indonesian Drug Users Network implemented a peer-led intervention aimed at

1. Improving IDU knowledge of HCV,
2. Providing free HIV/HCV testing in a community setting, and
3. Improving access to prevention, treatment and support services.

**Description:** Peer-driven intervention is an outreach model that relies on existing peer networks to reach and educate one another. Between August and December 2015, IDUs were recruited from urban sites in Jakarta using a coupon-referral system by which an initial community participant ('seed'), after being recruited to the project, was then provided with recruitment coupons and trained to educate and enlist additional peers. Participants were interviewed by trained peer fieldworkers using a structured questionnaire, provided HIV and HCV prevention, treatment and care information and materials, and offered free HIV and HCV testing and counseling.
**Lessons learned:** Of a total 326 IDUs participating in the intervention, the majority were male (86.2%; N=281) and unemployed (57.6%; N=188). Among those who agreed to be screened for HIV (N=321), seropositivity was 52.6% (N=169), with slightly higher rates among men (53.9%; N=149) than women (44.4%; N=20). Nearly 9 in 10 participants (87.2%; N=282) were HCV antibody positive. Men had higher levels of HCV (89.5%; N=247) than women (77.7%; N=35). At least 1 in 2 male IDU (52.8%; N=146) and 1 in 3 female IDU (37.7%; N=17) was HIV/HCV co-infected.
**Conclusions/Next steps:** The PDI model effectively utilized peer networks to reach, educate and test IDU groups who had not previously accessed prevention services. This suggests that the active role of the drug user community in recruiting, educating and referring their peers is central to achieving better HIV/HCV service coverage, reducing injecting risk behavior leading to blood borne virus transmission, and improving treatment access.

## TUPEE460

### MOVING TOWARDS THE SECOND 90: LINKAGE TO CARE AND THE ROLE OF A COMMUNITY MODEL OF CARE IN TETE, MOZAMBIQUE

E. Simons[1], T. Ellman[2], R. Giuliani[3], C. Bimansha[1], C. das Dores T.P. Mosse Lázaro[4], R. Nassiaca[4]
*[1]Médecins Sans Frontières, Tete, Mozambique, [2]Médecins Sans Frontières, Southern Africa Medical Unit, Capetown, South Africa, [3]Médecins Sans Frontières, Maputo, Mozambique, [4]Provincial Health Department, Tete, Mozambique*
*Presenting author email: esimons4@gmail.com*

**Background:** Community-based HIV testing and counseling (HTC) is an essential WHO-recommended complement to facility-based testing. Médecins Sans Frontières and the Mozambican Ministry of Health in Tete introduced Community ART groups (CAGs), a community-based strategy to simplify ART access, in 2008. Since 2012, the potential of CAGs to promote community testing and linkage to care has been explored at the community-level, including immediate connect of positive clients to CAG members and health facilities. The purpose of the analysis is to describe the linkage to care among individuals who tested positive in the community.
**Methods:** Retrospective analysis of routinely collected data included persons who tested positive in the community between July 2012 and December 2014. Individuals recorded in community testing registers were matched to electronic medical registers of facilities in Changara district. Linkage to care was defined as opening of a matched HIV file at a district facility within 6 months of test date. The linkage outcome was stratified by age, sex and testing referral method: immediate CAG family member (spouse, sibling, child or parent), other CAG contact (non-immediate family member or neighbor), other referral (community leader, community health worker or activist referral) or self-referral.
**Results:** Analysis included 772 positive persons, excluding forty individuals who had evidence of linkage prior to community testing. 77 % (597/772) linked within 6 months, including 82% in 2012, 70% in 2013 and 82% in 2014. 84% of children (< 15), 75% of youth (15-24), and 78% of adults (≥25) linked to care within 6 months. Self-referrals had higher linkage (85%) compared to patients referred by immediate family members in CAGs (79%), other CAG contacts (77%) or other referral (73%). Among 435 patients linked within 6 months and initiated on treatment before April 2015, the retention in care at 6 months was 88%.
**Conclusions:** Community testing with support from CAGs showed high levels of linkage to care regardless of approach to referral and has great potential to help achieve '90-90-90' targets. Further studies are needed to compare this approach with testing strategy at the health facility and community testing in areas without CAGs.

## TUPEE461

### DEMOGRAPHIC REACH AND COSTS ASSOCIATED WITH 3 MODELS OF COMMUNITY HIV TESTING IN RURAL KWAZULU-NATAL

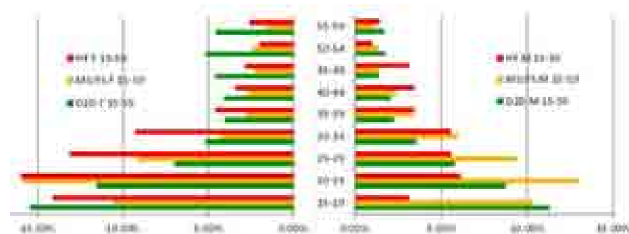
R. Bedell[1,2], A. Niyibizi[2], G. Martinez Perez[2], G. van Cutsem[2], S. Steele[2], G. Arellano[2], A. Shroufi[2]
*[1]University of British Columbia, Family and Community Medicine, Global Health, Vancouver, Canada, [2]Médecins Sans Frontières, Operational Centre Brussels, Cape Town, South Africa*
*Presenting author email: bedellrichard@gmail.com*

**Background:** The UNAIDS 90-90-90 targets demand HIV testing and counseling (HTC) for all sectors of the population at risk of HIV acquisition. Community testing modalities may offer better access than HTC at health facilities to some difficult-to-reach groups but at additional cost, which requires justification.
**Description:** MSF implemented 3 modalities of community HIV testing in uThungulu District beginning in 2012: Fixed Sites (FS), Mobile Sites, (MS) and Door-to-Door (D2D). An ingredients approach was used to analyze costs associated with these testing modalities for 2014. Client structures were analyzed for men and women 15-59 years of age for each testing modality, and compared to those of health facilities (HF).
**Lessons learned:** Costs per client varied from ZAR 192.55-249.70; D2D testing had the lowest cost per client (Table 1).

| Ingredients | | Fixed sites | Mobile sites | Door-to-Door |
|---|---|---|---|---|
| Total Tests (% positive) in 2014 | | 7065 (6.6%) | 11554 (3.3%) | 15112 (3.3%) |
| Category | Items | Cost/test | Cost/test | Cost/test |
| 1. HIV test supplies | Test kits HIV-/HIV+* | 7.9 / 24.9 | 7.9 /24.9 | 7.9 / 24.9 |
| | Testing supplies HIV-/HIV+ | 9.8 / 11.2 | 9.8 / 11.2 | 9.8 / 11.2 |
| 2.Salaries | Lay Counselor/ Community Health Agent(D2D) | 52.42 | 48.56 | 112.68 |
| | Support staff | 130.83 | 79.99 | 61.39 |
| 3. Logistics | Sensitization, phones, equipment, transport | 12.09 | 74.33 | 7.93 |
| Total cost | HIV- and HIV+ tests | 1,513,646.00 | 2,678,751.00 | 2,919,025.00 |
| Unit cost | Cost per test: HIV- / HIV+ | 212.95/ 231.44 | 231.21/ 249.70 | 192.55/ 211.04 |

*[Cost analysis for 3 modalities of Community HIV Testing. All costs in South Africa Rand (2014); *all have test 1, only HIV+ have test 2]*

HF testing costs ZAR 81.00-346.00 per client. The demographic reach of each modality differs. Both FS and MS see men and women of all ages, but age differs markedly depending on MS site: MS at commercial sites see similar clients to FS, but MS at high schools see predominantly younger clients up to 24 years of age (not shown). Both FS and MS are most effective at reaching men, especially 15-29, when compared with HF testing. Door-to-door testing reaches both sexes but with fewer men 20-34 than FS or MS commercial sites (Figure 1).



*[Client Structure of Community Testing Modalities compared to HF, proportion of all clients 15-59 for each modality; Female (left), Male (right) for HF]*

**Conclusions/Next steps:** Approaching the UNAIDS targets will require community testing modalities in addition to HTC at HF. Community testing increases testing of hard to reach and priority groups at affordable cost.

### LESSONS LEARNT FROM HIV TESTING RAPID RESULTS INITIATIVE (RRI) CAMPAIGN, KENYA, 2014

J. Wamicwe, J. Odhiambo, L. Nyagah, L. Dudah, P. Mwololo, M. Sirengo
*Ministry of Health, Preventive and Promotive Health, Nairobi, Kenya*
*Presenting author email: jwamicwe@yahoo.co.uk*

**Background:** The Kenya AIDS Indicator Survey (KAIS) 2012, showed that 53% of Kenyans with HIV were unaware of their HIV infection and a third of HIV-infected women, had taken their children for HIV testing. Targeted HIV testing is a key strategy that is outlined in the Kenya HIV Testing Guidelines (HTS).
**Description:** We conducted a 100 days rapid results initiative (RRI) campaign dubbed "Test and Link" that began in September 2014. Selected facilities throughout the country were purposively sampled based on programme HIV positivity yield data. HIV testing using rapid test kits was offered for all contacts of unknown status of index HIV-infected patients accessing HIV care clinics. HIV exposure was assessed for all infants accessing the Maternal Child Health (MCH) settings and subsequent collection of blood for Polymerase Chain Reaction (PCR) testing offered to all those whose exposure status could not be ascertained. Standard data collection tools were used to collect and collate data at facility level and transmit to the sub-county level and subsequently to the national level.
**Lessons learned:** HIV testing was carried out on 86% (n = 763,853) of the set target of 893,398 people. Of these, 67% (n = 601,032) comprised of contacts of index HIV-infected patients with 3.4% (n = 20,010) being HIV positive and 95% (19,017) of these being enrolled in care.
On average one contact was identified per index client and 38% of all identified contacts self-reported knowledge of their status. At the MCH setting, 17% (n = 150,287) mothers with unknown HIV status were tested with a positivity rate of 6%. Of the 1.5% (13,705) infants tested, 7.4% (n = 1,008) were HIV- infected and enrolled into care.
**Conclusions/Next steps:** The overall positivity rate from 2014 HIV testing programme data was 4.4%. Testing of contacts of index clients at the HIV care clinic yielded a lower positivity rate. However, testing of mothers with unknown HIV status accessing the MCH and infants with unknown HIV exposure status yielded a 36 - 68% more positivity rate than observed from the programme data. Testing at MCH setting should be optimized when implementing targeted testing at a health facility.

## GENDER-RESPONSIVE HIV PROGRAMMING

## TUPEE463

### GENDER INTEGRATION IN VMMC TO IMPROVE OUTCOMES: INVOLVING FEMALE PARTNERS

T. Harb Faramand[1], J. Byabagambi[2], A. Lawino[2], A. Twinomugisha[2], E. Njeuhmeli[3]
*[1]WI-HER, LLC, Vienna, United States, [2]USAID ASSIST Uganda, Kampala, Uganda, [3]USAID, Crystal City, United States*
*Presenting author email: atwinomugisha@urc-chs.com*

**Background:** The USAID Applying Science to Strengthen and Improve Systems (ASSIST) Project integrates gender as part of its work to strengthen health systems and build improvement capacity. Gender integration rests on the understanding that achieving sustained and equitable improvement requires a gender-sensitive approach that takes the different needs, constraints, and opportunities of women, men, girls, and boys into account and responds to them strategically in program design, implementation, and evaluation.
**Description:** ASSIST partner WI-HER, LLC developed an innovative and effective six-step approach to integrate gender throughout the program cycle to improve health outcomes. The approach has been tested in a variety of programs and improved outcomes. In VMMC programs, it led to female partner involvement in the form of group education, couples HCT, offering health services for women such as HIV testing, counseling and cervical cancer screening, and community mobilization and education. In looking at quality of care, our improvement approach allows for the consideration of cultural and gender norms, and helps to identify unintended negative results from changes introduced.
**Lessons learned:** In Uganda, ASSIST improvement efforts in VMMC led to adherence to international standards of care and procedures. Integrating gender by involving female partners resulted in increased adherence to the WHO-recommended 48-hour (98%) and 7-day (96%) follow-up and a decrease in adverse events. Our approach led to incorporating gender in VMMC assessment tools at the national level in Uganda and identifying the unintended negative consequences of prioritizing couples at VMMC services to encourage partner involvement (leaving single clients at a disadvantage), and newly circumcised boys dropping out of school (due to their new identity as men).
**Conclusions/Next steps:** Female involvement should become a standard aspect of VMMC programs, though more research is necessary to determine why we have not seen the same level of improvement for adherence to the 6-week visit or post-operative abstinence. Future improvement work must include consideration and research of long-term consequences like these, as well as issues of consent and coercion; by examining power dynamics and cultural and gender norms that influence circumcision, we can work to ensure the true consent of the client.

## TUPEE464

### "SOME OF THE THINGS I SAID...I WAS SAYING THEM FOR THE FIRST TIME": ADOLESCENT BOYS' EXPERIENCES PARTICIPATING IN A SPLIT-SEX HIV PREVENTION PROGRAMME IN SOUTH AFRICA

S. Dringus[1], J.H. Hargreaves[2], I. Warwick[3], A. Mbanga[4,5], P. Jibane[5], Z. Adam[5,6], L. Maloni[5], R. Hershow[7], Z.A. Kaufman[8], J. Decelles[5,9], E. Venables[10], D.A. Ross[11]
*[1]London School of Hygiene and Tropical Medicine, Department of Social and Environmental Health Research, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, Centre for Evaluation, London, United Kingdom, [3]University College London, UCL Institute of Education, Department of Education, Practice and Society, London, United Kingdom, [4]University of the Western Cape, Cape Town, South Africa, [5]Grassroot Soccer, Cape Town, South Africa, [6]Nelson Mandela Metropolitan University, Grahamstown, South Africa, [7]University of North Carolina, Gillings School of Global Public Health, Department of Health Behaviour, Chapel Hill, United Kingdom, [8]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [9]University of North Carolina, Gillings School of Global Public Health, Department of Health Policy and Management, Chapel Hill, United States, [10]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [11]London School of Hygiene and Tropical Medicine (Currently at WHO, Geneva), MRC Tropical Epidemiology Group, London, United Kingdom*
*Presenting author email: stefanie.dringus@lshtm.ac.uk*

**Background:** The importance of engaging adolescent boys in HIV prevention has come to the forefront of the global agenda. We explored adolescent boys' experiences and perceived relevance of participating in the Utshintsho programme, a split-sex curriculum focused on shifting male-dominant gender norms, implemented by the NGO Grassrooot Soccer and delivered by community facilitators in South African high schools.
**Methods:** As part of a larger process evaluation conducted alongside a cluster-randomised trial, six focus group discussions (FGDs), three each in Cape Town and Port Elizabeth township communities, were conducted with adolescent boys between October and December 2014. FGDs were conducted in Xhosa by local research assistants, audio-recorded, translated and transcribed. A thematic analysis approach was employed, transcripts were coded using an inductive and iterative process.
**Results:** Overwhelmingly, adolescent boys enjoyed the split-sex curriculum, saying that it provided a safe space where they could comfortably discuss and seek advice on issues that they were not otherwise able to talk about. However, they wished that the programme provided the opportunity for more joint sessions with adolescent females, so they could better understand female perspectives and exchange views and expectations regarding relationships. Topics that were cited as the most useful revolved around learning how to respect and interact with a partner, as well as developing more self-respect and self-efficacy. The most common suggestions for improving the programme included: increasing the length and number of sessions; starting earlier in their adolescent years; addressing other issues that they faced in everyday life such as gangsterism; and including the opportunity for parents and friends to be involved. Boys thought that these factors could increase the extent to which they could translate what they had learned in the programme into something meaningful for their lives.
**Conclusions:** This work builds on other literature that discusses the pros and cons of split-sex sexual and reproductive health education for adolescents. Boys perceived the split-sex curriculum to be engaging and relevant to their needs, but highlighted the need for it to include more space for dialogue with adolescent girls. Reaching adolescent boys at a young age with relevant, split-and-combined sex programmes is a critical opportunity.

## TUPEE465

### "HE CAN'T SAY A MAN'S STUFF TO A WOMAN..." MASCULINITIES AND MALE COMMUNITY HEALTH WORKERS IN CAPE TOWN, SOUTH AFRICA

L. Gittings[1,2]
*[1]University of Cape Town, AIDS and Society Research Unit (ASRU), Cape Town, South Africa, [2]University of Cape Town, Social and Behavioural Sciences Division, School of Public Health and Family Medicine, Cape Town, South Africa*
*Presenting author email: lesley.gittings@gmail.com*

**Background:** South African men seek HIV treatment less and at a later stage, have lower testing rates, and are more likely to be lost to follow-up or die on antiretroviral treatment (ART) than women. Norms of masculinity make it harder for men to access care because it is seen as a sign of weakness and femininity. Institutional supply-side barriers also contribute to men's poor rates of testing and treatment.
Recent evidence demonstrates that many South African men prefer to go to male-friendly clinics where they can be seen by male nurses and counsellors. In spite of the growing literature on clinic-based male-friendly services, there is a paucity of research on masculinities and HIV community health workers (CHWs).
CHWs play a central role in the provision of primary health care in South Africa. The deployment of an additional 20,000 CHWs is planned as part of the roll-out of National Health Insurance.
**Methods:**
· Multiple in-depth interviews with CHWs (N=8, 2 female and 6 male) and HIV and masculinities community experts (N=2) over a six-month period;
· Work-shadowing of CHWs, including observational home visits;
· In-depth joint interviews with male clients and their CHWs (N=3);
· Literature review of academic and grey literature on masculinities and HIV health care provision.
**Results:** Many HIV-positive men may prefer gender concordant CHWs. Improved adherence and health outcomes was reported among men with gender concordant CHWs.
In agreement with the literature on male-friendly clinic services, the rationale for male client preferences for gender-concordant CHWs included:
(1) comfort in sharing intimate health information with another man, and in some cases,
(2) the perception of female CHWs as untrustworthy gossips.
**Conclusions:** This research contributes to the small yet critical body of literature on masculinities and HIV care work. It shines light on the potential of male CHWs to improve health outcomes among men living with HIV. In view of the impetus towards meeting the targets of '90-90-90' and the increasing use of CHWs in delivering primary care, this research makes a compelling case for the role of male CHWs in supporting HIV-positive men.

# MODELLING, DEVELOPMENT, IMPLEMENTATION, AND EVALUATION OF HIV-RELATED POLICIES

### GENERATING MICRO-LEVEL HIV/AIDS ESTIMATES IN NIGERIA: FEDERAL CAPITAL TERRITORY AS CASE STUDY

M.C. Morka[1], E.N. Ngige[1], E.O. Abatta[1], B. Udu[2]
*[1]Federal Ministry of Health, Public Health, HIV/AIDS Division, Abuja, Nigeria, [2]Federal Capital Territory Administration, Human Services Secreteriat, Abuja, Nigeria*
*Presenting author email: nenyemercy@gmail.com*

**Background:** Estimates are generated to provide programme managers with approximation of persons needing certain services in a given population. In the face of dwindling resources to fight HIV/AIDS, many countries including Nigeria now focus intervention at the most burden populations. To achieve this, modelling of HIV estimates at micro-level has become necessary. In Nigeria, the burden of HIV differs from one location to the other. In many states of the country, the local government areas (LGA) have disproportionate burden of HIV due to the varying HIV prevalence and the population sizes. Presently, there are HIV estimates for all the states in Nigeria but they are not further disaggregated by the local government areas. Our focus was to generate local government estimates for HIV using the Federal Capital Territory (FCT) as the demonstration state.
**Description:** Using a Microsoft excel based model, we allocated the estimates generated from spectrum for FCT to the six area councils. HIV surveillance data from antenatal clinics and household surveys were used to generate estimates for FCT. The HIV prevalence trend generated from District Health Information System (DHIS) for PMTCT programme among women attending antenatal care in the six area councils were used to allocate the estimates for FCT to the area councils. Another variable that played key role in the model developed for allocation of HIV estimates to the area councils is the population size of each council.
**Lessons learned:** The estimated number of persons living with HIV (PLHIV) in FCT, number requiring ART and pregnant women needing PMTCT in year 2016 as allocated to the six area councils are shown in the table.

| Year 2016 | Adult 15+ | | Children (0-14) | | |
|---|---|---|---|---|---|
| | HIV+ | Need for ART | HIV+ | Need for ART | Need for PMTCT |
| *FCT* | *138,100* | *103,300* | *7,990* | *4,860* | *7,250* |
| AMAC | 85,600 | 64,000 | 4,950 | 3,010 | 5,050 |
| BWARI | 37,500 | 28,100 | 2,170 | 1,320 | 1,630 |
| KUJE | 6,300 | 4,700 | 360 | 220 | 120 |
| GWAGWA-LADA | 4,100 | 3,100 | 240 | 150 | 300 |
| ABAJI | 2,300 | 1,700 | 130 | 80 | 50 |
| KWALI | 2,300 | 1,700 | 140 | 80 | 100 |

*[FCT estimates allocation to Area Councils]*

**Conclusions/Next steps:** Micro-level estimates can be generated for the 36 states in Nigeria and FCT. These estimates will help to prioritize LGA most burden by HIV. Caution should be applied while programming based on the estimates since PLHIV access services across LGAs.

## TUPEE467

### HIV PATIENTS' BARRIERS TO START ANTIRETROVIRAL TREATMENT (ART): THE GREEK EXPERIENCE

P. Panagopoulos[1,2], V. Papastamopoulos[3], P. Gargalianos-Kakolyris[4], M.-K. Lazanas[5], S. Metallidis[6], P. Nikolaidis[6], J. Fehr[7], D. Nicca[8], I. Katsarolis[9], J.-C. Goffard[10], V. Paparizos[11], G. Petrikkos[2], H. Sambatakou[12], A. Skoutelis[3], B. Ledergerber[7]
*[1]University General Hospital of Alexandroupolis, Alexandroupolis, Greece, [2]ATTIKON University Hospital, Athens, Greece, [3]Evangelismos General Hospital, Athens, Greece, [4]General Hospital 'Georgios Gennimatas', Athens, Greece, [5]'Korgialenio-Benakio' Red Cross General Hospital, Athens, Greece, [6]University General Hospital of Thessaloniki AHEPA, Thessaloniki, Greece, [7]Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland, [8]Division of Infectious Diseases and Hospital Epidemiology, Cantonal Hospital of St. Gallen, St Gallen, Switzerland, [9]Gilead Sciences Greece, Hellinikon, Greece, [10]Internal Medicine AIDS Reference Centre, ULB-Hôpital Erasme, Brussels, Belgium, [11]Andreas Syggros' Hospital of Cutaneous & Venereal Diseases, Athens, Greece, [12]Hippokration General Hospital, Athens, Greece*
*Presenting author email: ppanago@med.duth.gr*

**Background:** To assess the degree of discordance of perceived barriers to treatment initiation between physicians and treatment-naïve HIV(+)individuals and to investigate possible physician and patient-described reasons for deferring treatment initiation.
**Methods:** Treatment-naïve HIV(+)individuals and their physicians from 8 sites in Greece completed independently a 59-item questionnaire about barriers and readiness to start/defer ART, assessing 11 domains. This is a sub-group analysis of the multi-national study of 442 patient-physician pairs in Australia and 9 European countries for the period 12/2011-10/2012. Regarding the readiness stages, concordance was measured using Kappa statistics. Answers were measured using a 5-point Likert-scale and discordance scores were calculated using the absolute difference between patient-physician answers. This score varied between 0(same answer) and 3(opposite answer). A score≥2 defined discordance. Logistic regression was used to analyze factors associated with discordance.
**Results:** Between 3/2012-10/2012, 138 pairs of patients' and physicians' questionnaires were completed. 127/138 patients (92.3%) were male and 54% completed the questionnaire between 1-5 years since first HIV-positive test (median age 37 ys-MSM 74%). Physicians were very experienced (82.4% cared for >50 patients and had>5ys of experience). In Greece patients had higher readiness to start medication (24.15% replied "don't need HIV meds at the moment" vs. 75.7% in total cohort, Fisher-exact 0.270) and concordance regarding patients' readiness was higher (Kappa:0.3421 vs 0.2736, indicates fair agreement). Most important reasons for patients not to start ART were "I am scared of the side effects it may cause" and "Worried my body shape might change if I start"(ART beliefs domain) and "I don't want to think about HIV". Discordance between physicians and IDUs was greater than that observed for MSM, stemming from health beliefs domain (similar to the total cohort) plus provider communication issues and social circumstances domains.

Tuesday 19 July Poster Exhibition

Wednesday 20 July

Thursday 21 July

Friday 22 July

Late Breaker Posters

Author Index

**Conclusions:** Probable side effects and body awareness are the most common barriers to start ART for patients. Discordance between patients' views and physicians' perceptions regarding ART initiation was substantial, especially in IDUs. Communication and understanding between physician and patient is important to overtake obstacles regarding ART initiation, especially in the context of the local recent epidemiology and changes in guidelines concerning earlier ART initiation.

## TUPEE468

### MORTALITY ASSOCIATED WITH FASTER TRANSITIONS ALONG THE CASCADE OF CARE IN KWAZULU NATAL, SOUTH AFRICA

N. Haber[1,2], J. Salomon[1], D. Pillay[2], T. Bärnighausen[1,2]
*[1]Harvard TH Chan School of Public Health, Global Health and Population, Boston, United States, [2]Wellcome Trust Africa Centre for Population Health, Mtubatuba, South Africa*
*Presenting author email: noahhaber@gmail.com*

**Background:** While major international HIV/AIDS agendas, such as UNAIDS' "90-90-90," call for quickening movement along the cascade of care, little is understood about risk of mortality differences among those who select into transitioning faster vs slower. While individuals who link to care faster are more likely to receive treatment, they also may be entering care due to already poor HIV-related health. There are therefore opposing "illness" and "treatment" effects with regard to the relationship between speed of transition and mortality.

**Methods:** This study utilizes the Wellcome Trust Africa Centre Demographic Information System in rural KwaZulu-Natal, South Africa, a longitudinal health and demographic surveillance system composed mainly of annual household and individual survey data linked with HIV-related clinical records and laboratory results. We utilized longitudinal data from individuals who were first tested positive in surveillance HIV testing from 2006-2011, and define linkage to care as the first time an individual has an HIV-related clinic visit, such as a CD4 test. We utilized survival analytic methods to estimate mortality differences among those who transitioned from first testing positive faster, slower, or never.

**Results:** 3,106 individuals met our criteria, with 410 recorded deaths among them. Contrary to expectations, those who were faster to transition had 1.34 (95%CI: 0.99-1.81) times the hazard of mortality compared to those care more quickly. However, the relationship between speed of transition and mortality is complicated. Those who were in the slowest to transition quartile had 0.62 (95%CI: 0.41-0.95) times the hazard of mortality compared to those who were never linked to care, while those in the fastest to transition quartile had 1.66 (95%CI: 1.16-2.38) times the hazard of mortality.

**Conclusions:** In this population, the illness effect outweighs the treatment effect in the relationship between faster transition to care with mortality. This suggests that improving and shortening linkage to care would have less of an impact on mortality among those who would not have otherwise self-selected into care. While this study is limited to mortality as an outcome, earlier linkage to care may have additional beneficial effects across other health and well-being outcomes.

## TUPEE469

### DO PATIENTS PREFER RECEIVING ANTIRETROVIRAL THERAPY AT A PRIMARY CARE FACILITY? EVIDENCE FROM A CHOICE EXPERIMENT IN NORTHEAST THAILAND

T. Kitajima[1], N. Leeratanapetch[2], V. Wattananamkul[3], S. Muadthong[4], K. Muangyim[5], T. Khotphuwiang[2], N. Krucien[6], Y. Kobayashi[7], S. Naprasert[2], R. Prommueang[2]
*[1]Kyorin University, Faculty of Social Sciences, Tokyo, Japan, [2]Khon Kaen Hospital, Khon Kaen, Thailand, [3]Khon Kaen University, Khon Kaen, Thailand, [4]Sirindhorn College of Public Health, Khon Kaen, Thailand, [5]Sirindhorn College of Public Health, Chonburi, Thailand, [6]University of Aberdeen, Health Economics Research Unit, Aberdeen, United Kingdom, [7]University of Tokyo, Graduate School of Medicine, Tokyo, Japan*
*Presenting author email: kitajima@ks.kyorin-u.ac.jp*

**Background:** In Thailand as in many other countries, public hospitals play a major role in providing antiretroviral therapy (ART); however, it is becoming difficult for them to fully address the needs of the growing number of patients receiving ART. In order to continue expanding the coverage effectively, shifting a task of providing ART from hospitals to primary care facilities (PCFs) should be a policy option. It is not clear, however, whether patients prefer to receive ART at PCFs and what factors might promote them to have such preference. Information is necessary for designing the delivery system of ART. This study explored patients' preference for receiving ART at PCFs.

**Methods:** We conducted a labeled discrete choice experiment (DCE) with patients who were receiving ART at a tertiary hospital in northeast Thailand. DCE is an attributed-based survey method for measuring preferences. The patients were asked to choose between two scenarios of ART provision, at the hospital or at PCFs located in the vicinity of the hospital. ART provisions differed in five attributes: (1) type of clinic (special clinic for ART/general clinic), (2) service hours, (3) length of waiting time, (4) type of physician (general physician/HIV specialist), and (5) the amount of out-of-pocket payment. Data were analyzed using a conditional logistic regression model.

**Results:** Of 357 respondents, the average age was 41.2±7.5 and 52% were female. All attributes except service hours were significant in their decision to choose PCFs. Type of clinic, waiting time, and type of physician were relatively important attributes. Compared with a scenario comparable to the current situation where they have to wait for 4 hours to see an HIV specialist at the hospital, 43% of them prefer PCFs if a general physician can provide ART with less than 1 hour of waiting time.

**Conclusions:** This study showed that patients prefer to receive ART at PCFs, but their preference varied depending on the attributes of PCFs. Such information is valuable to facilitate policy making of shifting the task of providing ART from the hospital to PCFs in future.

## TUPEE470

### HOW INEXPENSIVE DOES PREP NEED TO BE IN ORDER TO DELIVER FAVORABLE VALUE IN RESOURCE CONSTRAINED SETTINGS

E.R. Stevens[1,2], K.A. Nucifora[1], J. Kessler[1], R.S. Braithwaite[1]
*[1]New York University School of Medicine, Population Health, New York, United States, [2]NYU College of Global Public Health, New York, United States*
*Presenting author email: elizabeth.stevens@nyumc.org*

**Background:** Pre-exposure prophylaxis (PrEP) has been shown to prevent HIV infection if taken consistently and adherence to PrEP has been demonstrated as feasible in resource limited settings. However, in spite its potential health benefit, PrEP is not implemented due to its cost. Our objective was to use a computer simulation to determine the cost necessary for PrEP to become cost-effective in limited resource settings.

**Methods:** We developed a deterministic computer simulation to inform HIV prevention decisions in Kenya. This simulation is composed of a probabilistic microsimulation of HIV progression and a deterministic compartmental model of HIV transmission in a hypothetical population. We conducted a simulation to estimate the health benefits, costs, and cost-effectiveness ratio over a twenty year time horizon for availability of PrEP compared to no PrEP for individuals with multiple concurrent sexual partners, explicitly considering adherence levels observed in clinical trials. In baseline analyses the cost of PrEP was estimated at $165/person per year, and in sensitivity analyses we identified the cost of PrEP necessary to bring the incremental cost effectiveness ratio (ICER) down to that of other programmatic priorities, in particular those consistent with WHO recommendations (willingness to pay threshold of $2,600/QALY).

**Results:** In the reference scenario the model predicted 1,513,474 new HIV infections over 20 years, with associated cost of care and treatment for all infected persons estimated at $9.7 billion ($0.49 billion per year). The implementation of PrEP would avert 788,560 new infections over 20 years, for a total of 1,248,164 QALYs gained. At its current cost of $0.42 billion per year, PrEP has lower value than other programmatic priorities (ICER $19,322). The cost of PrEP would need to decrease to $29 for it to have favorable value consistent with willingness to pay thresholds (ICER $2600/QALY). If targeted at those with the highest number of concurrent sexual partners (i.e. sex workers), PrEP would have favorable value at $57.

**Conclusions:** If the price of PrEP came down to $29, it would have favorable value and could become a key strategy for HIV prevention in East Africa. Further targeting to high risk groups would enhance its value.

## TUPEE471

### RESULTS OF TESTING COST-YIELD PRIORITIZATION MODEL FOR TEST AND TREAT IN BOTSWANA

S. Procter[1], H. Phillips[2], W. Mosime[3], B. Nkomo[4], A. Avalos[3], E. Mmatli[4], C. Petlo[4], P. Loeto[5], E. Hulela[4], M. Mine[4]
*[1]Clinton Health Access Initiative, Boston, United States, [2]UNAIDS, Gaborone, Botswana, [3]Careena Centre for Health, Gaborone, Botswana, [4]Botswana Ministry of Health, Gaborone, Botswana, [5]Centers for Disease Control and Prevention, Gaborone, Botswana*
*Presenting author email: sethprocter@gmail.com*

**Background:** The Government of Botswana is considering the adoption of a test and treat program that will achieve epidemiological control of HIV by 2020. The initiative will require treating an additional 129,000 patients by 2020, which amounts to retaining 95% of People Living with HIV (PLHIV) on treatment. In order to achieve this target it will be necessary to expand current HIV testing services (HTS) and in-

troduce HIV Self-Testing (HIVST), to intensify index testing, and to ensure universal routine HIV testing at key entry points.
**Description:** A comprehensive HTS model was developed and populated, drawing on government data and published literature to construct a cost per patient identified and linked to treatment using 20 unique testing approaches. The cost per patient linked to treatment was primarily a function of the expected proportion of positive test results (yield), the rates of linkage to care, and the cost per test under each testing approach. Testing approaches were prioritized based on their cost and efficiency with consideration for the maximum number of patients that could be identified using each testing strategy.
**Lessons learned:** In the first year, 2016, the cost per patient linked to treatment ranges from $17 to $282. Index testing, sex worker outreach, and TB screening all cost less than $21 per patient identified. The most expensive strategies are campaign and outreach for young woman and outreach to men who have sex with men (MSM). With declining testing yields as the number of patients on treatment increases, identifying and linking additional patients in later years will require more tests, even with the highest yield and most cost-effective strategies used. By 2020, the minimum cost per patient linked to treatment will rise to $44, with the maximum cost at over $1,000.
**Conclusions/Next steps:** Reaching the treatment targets by 2020 will require increasing the total number of HIV tests conducted in 2020 by 2.4 times from the number completed in financial year 2014-2015, from approximately 400,000 to 950,000. In order for the health system to conduct this many additional tests HIVST will need to account for nearly half of all HIV tests conducted by 2020.

## TUPEE472

### SIMPLE RULES FOR THE STRATEGIC ALLOCATION OF HIV PREVENTION INTERVENTIONS ACROSS GEOGRAPHIES

S.-J. Anderson[1], P.D. Ghys[2], T.B. Hallett[1]
*[1]Imperial College London, London, United Kingdom, [2]UNAIDS, Geneva, Switzerland*
*Presenting author email: sarah-jane.anderson@imperial.ac.uk*

**Background:** Geographical heterogeneity in the HIV epidemic provides the opportunity to tailor intervention choices to local epidemiology and prioritise resources to those at highest risk. Such geographical prioritisation is increasingly being deployed in an attempt to make HIV prevention spending more efficient. Here, we compare candidate simple rules for the allocation of HIV prevention interventions across geographies to inform application of this strategy.
**Methods:** We explore different methods for the allocation of male circumcision, behaviour change, early ART and PrEP interventions across counties and cities ('locations') in Kenya. These strategies include:
1. 'Restriction to priority locations'- locations are classified into prevalence categories (very high, high, medium and low prevalence) and all interventions are provided at maximum levels in locations of a prevalence category before moving to lower categories.
2. 'Simple division' approaches, where the total budget is divided across locations proportional to the number of PLHIV in each location. The subsequent intervention choices are either based on a national policy or tailored to the local epidemic.
We compare the impact of these geographically tailored strategies with a nationally uniform approach, i.e. identical interventions across all locations, at a number of prevention budget levels using dynamic transmission modelling. We assess whether such geographically specific approaches perform better than country-wide policies.
**Results:** The 'restriction to priority locations' approach may avert up to 39% fewer infections than the nationally uniform approach. This is as interventions are provided to only a small number of locations, restricting the impact that is possible through not gaining the benefits of highly cost effective interventions in lower prevalence areas. The 'simple division using national policy' approach performs similarly to the nationally uniform approach as intervention choices are not tailored to local epidemiology. In contrast, the 'simple division using local strategies' approach performs consistently stronger, with up to 15% more infections averted compared to the nationally uniform approach through targeting resources to high burden locations and tailoring intervention choices.
**Conclusions:** The greatest impact is achieved through the 'simple division using local strategies', suggesting that prioritisation should take into account local epidemiology and not be restricted only to a small number of priority locations.

## TUPEE473

### NEW CASE DETECTION THROUGH COMMUNITY HIV TESTING AND COUNSELING

K. So
*Khmer HIV/AIDS NGO Alliance (KHANA), Program Management Department, Phnom Penh, Cambodia*

**Background:** Cambodia's Integrated Bio-Behavioral Survey (IBBS) in 2014 indicated that an estimated 75,000 people currently live with HIV. The Cambodian government has put efforts into ensuring that 90% of these individuals will know their HIV status by 2020. The current programme is facing challenges in reaching key populations (KPs), including MSM, TG, EW and PWID to receive HIV testing and counseling (HTC).
**Methods:** As part of the Flagship Consortium, KHANA collaborates with the National Center for HIV/AIDS, Dermatology and STD (NCHADS) of the Ministry of Health to deliver training for outreach workers from Implementing Partners (IPs) and Centers of Excellence. Joint monitoring visits from national counterparts and Flagship teams are conducted regularly to make sure IPs can perform HTC properly. Reactive cases are referred to complete confirmatory tests at health facilities and followed-up with support for enrollment in care and treatment. Both community and health facilities work together to detain PLHIV in care service till viral load suppression.
**Results:** Based on the programmatic report from Flagship and the Implementing Partners from January 2014 to September 2015, 71% of 37,185 of EW, 51% of 13,431 MSM, 29% of 1,829 TG, and 48% of 376 PWID were reached and provided with HTC (through community-based finger prick testing). It is of note that HIV positivity is (0. 5%, 0.5%, 1.9%, 5.5% among EW, MSM, TG, and PWID respectively). It is recommended that the client tracking system, information update on new HIV cases and new case detection procedure (including HTC) be swiftly improved, regularly monitored and widely disseminated among key stakeholders to ensure timely and effective response.
**Conclusions:** The number of KPs having access to HTC is still low due to some factors, such as mobility of KPs, perceived lack of trust in and confidentiality of HIV test results, and unwilling to disclose HIV status because of stigma and discrimination. NCHADS and IPs also introduce a new approach called "IRIR" (Identify, Reach, Intensify and Retain) aiming at reaching KPs to increase HIV testing, strengthens new case detection, and promoted health service update.

## TUPEE474

### RESULTS FROM A PROCESS OF EVIDENCE SYNTHESIS AND POLICY DIALOGUE FOR COMPREHENSIVE HIV PREVENTION AND CARE FOR TRANSWOMEN IN PERU: A CASE STUDY

C.F. Caceres[1], X. Salazar[1], A. Borquez[2], A. Silva-Santisteban[1], A. Motta[1], A. Nunez-Curto[1], J.V. Guanira[1], P. Bracamonte[3], C. Benites[4], P. Caballero[5]
*[1]Universidad Peruana Cayetano Heredia, Center for Interdisciplinary Studies in Sexuality, AIDS and Society, Miraflores, Peru, [2]University of California, San Diego, San Diego, United States, [3]UNAIDS, Regional Office for the Andean Area, Lima, Peru, [4]Ministry of Health of Peru, National HIV Strategy, Lima, Peru, [5]Ministry of Health of Peru, Division of People's Health, Lima, Peru*
*Presenting author email: carlos.caceres@upch.pe*

**Background:** Transwomen (TW) in Peru remain, by far, the community most affected by HIV, with prevalences over 20%, and low access to prevention, testing and care, resulting from stigma and social exclusion. However, a transition from traditional to combination prevention for key populations had not occurred. In 2014 an initiative emerged, consisting of a process of evidence synthesis for decision-making, and a policy dialogue among stakeholders, including the Ministry of Health (MoH), academia, civil society, TW leaders and international agencies, Such initiative supported the development and implementation of the first Plan for Comprehensive HIV Prevention and Care among TW in Peru.
**Methods:** A mixed-methods study to gather evidence for combination HIV prevention investigated stakeholders' perspectives on existing and novel HIV prevention methods, assessed health systems' needs and overall costs, and used mathematical modelling to estimate impact and cost-effectiveness of specific intervention combinations to reduce the HIV incidence burden among TW, with emphasis on sex workers, taking the system's capacity into account. A community-led mapping of TW sex work settings was also conducted.
**Results:** Information about combination prevention is limited among communities and providers alike, and misconceptions lead to resistance to change; health facilities require improved processes to respond to new needs. The Mathematical Modeling predicted higher effectiveness and cost efficiency for various combinations of prevention strategies. Policy dialogue was fostered through a National Consultation which allowed for discussion of new evidence and avenues for change. From this platform, a new plan was devised, which includes new National Guidelines for HIV prevention, care and support; and country-level investment in infrastructure and equipment. In addition to biomedical strategies (i.e. enhanced testing linked to care, test and offer, improved condom provision; potentially PrEP), the plan ac-

knowledges the need of, and incorporates, structural strategies (community capacity building; advocacy for official recognition of name/gender of choice; dedicated TW clinics offering complementary services).
**Conclusions:** This study shows how evidence-informed political will and multisectoral collaboration can lead to policy change based on sound public health and human rights principles, aiming to tackle the HIV needs and other health and social burdens that still characterize the experience of transgender women in Peru.

## TUPEE475

### USING MATHEMATICAL MODELING TO INFORM POLICY PLANNING, IMPLEMENTATION AND MONITORING: THE EXAMPLE OF VMMC SCALE UP IN EASTERN AND SOUTHERN AFRICA

E. Njeuhmeli[1], A. Vazzano[2], P. Stegman[3], K. Kripke[3], M. Schnure[2], D. Castor[1], B. Lori[3], J. Stover[3], S. Forsythe[3], C. Hankins[4]
*[1]US Agency for International Development, Washington, DC, United States, [2]Project SOAR, Palladium, Washington, DC, United States, [3]Project SOAR, Avenir Health, Washington, DC, United States, [4]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands*
*Presenting author email: enjeuhmeli@usaid.gov*

**Background:** Modeling can be a critical tool for HIV program planning, allowing users to estimate outcomes, such as HIV incidence, that are otherwise impossible to measure. In 2007, in light of evidence that voluntary medical male circumcision (VMMC) reduces HIV acquisition in men, WHO and UNAIDS prioritized 13 countries for rapid scale-up to 80% MC prevalence. Since then, models such as the Decision Maker's Program Planning tool (DMPPT) and the DMPPT 2 have been used to describe the epidemiologic impact and cost associated with MC scale-up. The authors explore the influence of these models on VMMC policies and programs at country and global levels.
**Description:** In 2011, results from the DMPPT, a Microsoft-Excel-based modeling tool, demonstrated that VMMC scale-up would result in substantial reductions in HIV infection and lower health system costs. The analysis informed advocacy that led all priority countries to commit to reaching this goal, and was incorporated into the WHO-UNAIDS Joint Strategic Action Framework for VMMC in December 2011. In response to questions arising from implementation experience, a revised model (DMPPT 2) enabled analyses of impact and cost-effectiveness by age group and subnational region starting in 2013. Results were incorporated into operational and strategic plans in Tanzania, Malawi, Uganda, South Africa and Swaziland, and informed global guidance from PEPFAR and UNAIDS. A new version (DMPPT 2.1) allows countries to better monitor their progress by generating targets, assessing impacts to date, and disaggregating estimates by age and district. This information is critical to countries to move from scaling up VMMC to maintaining coverage levels, and to PEPFAR for Country Operational Planning.
**Lessons learned:** Modeling can be an effective tool for advocacy as well as strategic planning and monitoring. It is most useful when it is conducted in collaboration with country teams and addresses country-generated questions. Country ownership helps to ensure model results are incorporated into national strategies and implementation plans.
**Conclusions/Next steps:** Models can be used to mobilize, strategically implement, and monitor key programmatic elements in an HIV response. The ways in which modeling has informed VMMC programs and policy may be applicable to other HIV program areas and interventions.

## TUPEE476

### PEPFAR IN NIGERIA: PROMISE, PITFALLS AND POLICY

O. Omole[1], O. Falope[2], T. Folaranmi[3], B. Adenuga[1]
*[1]Howard University Hospital, Community and Family Medicine, Washington DC, United States, [2]University of South Florida, College of Public Health, Tampa, United States, [3]Stream Insight Inc, Lagos, Nigeria*

**Background:** Approximately 3.5 million Nigerians live with HIV and only about 27% of individuals who need HIV medication get them through the US government funded PEPFAR program . Many reasons have been adduced for the inability of Nigeria to support the medication needs of its PLWHA.
With the recent rebasing of the Nigerian economy, Nigeria is now a middle income country with the potential to raise local funds and self fund its HIV programs but this is not happening yet. The US government has supported Nigeria's PEPFAR program since 2004 but questions have been asked about how long the support would continue. There is also an ongoing aid effectiveness policy debate with regards to HIV/AIDS. The recent drop in oil prices has also raised questions about the ability of Nigeria to begin to transition to self fund its HIV/AIDS programs.
**Description:** Using questionnaires and conducting Interviews with critical stakeholders such as the Ministry of Health, Development Partners, Donors, and Non-Governmental Organizations, we analyze the PEPFAR program in Nigeria. We also conducted a critical review of relevant literature involving PEPFAR donations to Nigeria. We also reviewed literature on the reports of donors, Country Aid Effectiveness reports and evaluations with a focus on Nigeria, From these we analyse the promise and pitfalls of the PEPFAR program in Nigeria. We also suggest policy change with regards to HIV/AIDS policy
**Lessons learned:** From our analysis, we suggest effective coordination and accountability efforts which can help to transition from a PEPFAR supported program to a locally owned and directed program. More specifically,we highlight the technical, managerial, and political capacities required for effectively developing a self funded program for HIV/AIDS medications in Nigeria.
**Conclusions/Next steps:** Nigeria must begin to pay attention to domestic and alternative sources of raising funds to fund its HIV/AIDS programs and depend less on donors. This would potentially lead to improved access for people living with HIV/AIDS who need medication.

# PROCUREMENT AND SUPPLY CHAIN MANAGEMENT

## TUPEE477

### USE OF AN HIV AND AIDS COMMODITY MANAGEMENT TOOL (DASHBOARD) TO IDENTIFY THE RISK AND PREVENT STOCK-OUTS OF ARVS IN WEST AFRICA: THE TOGO EXPERIENCE

J.B. Evi[1], A.K. Assimadzi[2], S. Doumbia[3], D. Mabirizi[3], A. Tokofai-Singo[2], F. Aboagye-Nyame[3], L. Kapesa[4]
*[1]Management Sciences for Health (MSH), USAID-funded Systems for Improved Access to Pharmaceuticals and Services Program (SIAPS), Accra, Ghana, [2]Programme National de lutte contre le SIDA et les IST (PNLS - Togo), Lome, Togo, [3]Management Sciences for Health (MSH), USAID-funded Systems for Improved Access to Pharmaceuticals and Services Program (SIAPS), Arlington, United States, [4]Unites States Agency for International Development (USAID), West Africa Regional Health Office, Accra, Ghana*
*Presenting author email: bevi@msh.org*

**Background:** Alerts on stock-outs of lifesaving antiretrovirals (ARVs) emerged in a number of countries in the West African region in 2012/2013. Several root causes have been identified, such as the lack of tools to improve the sharing of HIV and AIDS commodity information among stakeholders for faster decision making. Togo lacked the tools to estimate the number of patients at risk of missing their ARVs when stock-outs occurred.
**Description:** The USAID-funded SIAPS Program has developed and deployed the HIV and AIDS dashboard known as OSPSIDA in six West African countries. In December 2014, Togo was alerted to the risk of a stock-out of ARVs. SIAPS supported the National AIDS Control Program to use the dashboard to incorporate patient and commodity data to assess the impact of a potential stock-out on patients receiving ARVs.
**Lessons learned:** Updating OSPSIDA with 2014 data revealed that 71% of ARVs in use at Togo were at high risk of stock-out at the national level (months of stock was less than six months) putting 96% of patients at high risk of treatment interruption. The data in the dashboard showed that this risk should have been identified 6-9 months earlier. The improved use of data for decision making using this dashboard has resulted in detection of impending stock-outs up to six months earlier. The percentage of patients at high risk of treatment interruption (table 1) was reduced from 96% to less than 1% in November 2015.

| Month | Dec 14 | Jan 15 | Feb 15 | Mar 15 | Apr 15 | Jun 15 | Aug 15 | Sep 15 | Nov 15 |
|---|---|---|---|---|---|---|---|---|---|
| % of ARVs at high risk | 71 | 69 | 59 | 53 | 33 | 24 | 11 | 11 | 5 |
| % of patients at high risk | 96 | 92 | 88 | 79 | 74 | 61 | 2 | 2 | <1 |

*[Table 1. Risk Assessment in Togo]*

**Conclusions/Next steps:** Deploying OSPSIDA in Togo has significantly enhanced the visibility of supply chain data for timely and evidence-based decisions that have contributed to the increased availability of HIV and AIDS products within a year. We strongly encourage other countries to use the dashboard as a tool to assess the number of HIV positive patients at risk of missing their ARVs to make the right decisions at the right time to prevent the hurried choices that are frequently made when a stock-out occurs.

## TUPEE478

### "SELF-INITIATIVE SCM STRENGTHENING" APPROACH USED IN DECENTRALISATION OF ARV MANAGEMENT TO DISTRICT LEVEL TO INCREASE ACCESS OF ART FOR PEOPLE LIVING WITH AIDS: PILOT IN TWO PROVINCES IN INDONESIA

S. Nadia[1], H. Masoed[2], D. Wahu[3], S. Suparan[4], N. Sukasediati[4], R. Vogel[4]
*[1]Minister of Health, Subdit HIV/AIDS, Communicable Diseases, MOH, Jakarta, Indonesia, [2]Ministry of Health, Indonesia, Directorate of Public Medicine, MoH, Jakarta, Indonesia, [3]Ministry of Health, Subdit HIV/AIDS, Communicable Diseases, MOH, Jakarta, Indonesia, [4]PtD Forum Indonesia, Jakarta, Indonesia*
*Presenting author email: russjsi2009@gmail.com*

**Background:** Since the National HIV/AIDS Program's establishment in the 1990s, the ARV supply chain for 14 drugs was managed at the central level. To expand coverage throughout this large country and address the growing number of service points, the HIV/AIDS Program launched the "SUFA" activity in 2013, which decentralised the HIV/AIDS Program to the district level. A Pilot was initiated in 2014 to insure ARV SCM good practices at the district level.
**Description:** Critical issues regarding ARV decentralization were anticipated, including the need for:
1) strong district health office (DHO) commitment,
2) proper staff technical capability, and
3) standard drug storage facilities to manage 14 types of ARVs.
These critical issues must be addressed for smooth ARV decentralisation. In 2014-2015, the MOH initiated a Pilot in two provinces, Bali, on one island, and Riau, on eight islands, covering 12 districts, to identify methods for good ARV district decentralisation.
The Pilot used a locally developed "Self-Initiative SCM Strengthening" approach (SI-SCM-S) that is now institutionalized at the MOH as one means to strengthen SCM good practices.
This SI-SCM-S approach starts with building commitment among DHO staff for SCM. Second, a joint district SCM self-assessment by drug management and HIV Program staff is undertaken to identify SCM strengths and weaknesses. Third, the SCM self-assessment results are placed in a joint SCM "Corrective Action Plan" (CAP), consisting of planned activities to address SCM problems. Lastly, a training workshop is held to provide knowledge to address key SCM problems.
**Lessons learned:** The SI-SCM-S approach did increase awareness and commitment of senior officers at DHOs for decentralisation of ARVs, included immediate improvements to storage facilities, and breakthrough policies regarding insufficient SCM human resources.
Also, a SI-SCM-S approach has significant, positive impact on the SCM good practices.
Finally, the SI-SCM-S can strengthen coordination and communication among staff.
**Conclusions/Next steps:** DHOs with high commitment will more likely establish necessary coordination among program and drug managers, maintaining good SCM practices.
SI-SCM-S helped all 12 Pilot districts achieved 80% of the Pilot indicators for SCM good practices and is now being used in other districts.

## TUPEE479

### SUPPLY CHAIN CONSIDERATIONS WHEN ROLLING OUT 'TEST AND TREAT' APPROACHES: A CASE STUDY OF UNIVERSAL TREATMENT FOR CHILDREN UNDER 15 YEARS IN UGANDA

V.S. Mulema[1], A. Kabbale[1], M. Amuha[2], I. Lukabwe[2], B. Asire[2], E. Magongo[2], C. Katureebe[2], P. Elyanu[3]
*[1]Clinton Health Access Initiative, HIV Access Team, Kampala, Uganda, [2]Ministry of Health, STD/AIDS Control Program, Kampala, Uganda, [3]University of Texas, School of Public Health, Houston, United States*
*Presenting author email: vivmulema@gmail.com*

**Background:** Following a review of the 2013 WHO recommendations and national data in August 2013, Uganda decided to treat all children under 15 years - or 'Test and Treat' - regardless of CD4 count or WHO staging. A total of 21,000 children in chronic care became newly eligible for treatment. The country also adopted Abacavir-based regimens as the preferred first line therapy for HIV-infected children. CHAI set out to support the MoH to roll out these guidelines with minimal stock disruptions.
**Description:** The pediatric ARV quantification methodology was revised to include age and weight band breakdown thereby generating a more accurate forecast. Orders were placed in September 2013 in order to have stock in-country in time for the start of the roll out in June 2014. Training was conducted at facilities rather than in workshop settings which cut costs and ensured that more health workers received the information. Health facilities used the 'pull' method during the regular warehouse order schedule to obtain stock. Patient numbers to order for were derived using a tool developed by CHAI to mitigate prescriber preferences. A free online survey tool was used to monitor the number of facilities trained and this information was correlated with facility orders.
**Lessons learned:** There were no stock outs of pediatric formulations at national level between June and December 2014. Stock availability at facilities ranged between four and seven Months of Stock. Over 10,000 children in Pre-ART had been initiated on treatment by September 2015. Furthermore, these children were initiated on the preferred Abacavir formulations as compared to Zidovudine in line with the national quantification as shown by an increase in the number of packs consumed.
**Conclusions/Next steps:** It is feasible to forecast accurately and mitigate prescriber preference by providing targeted quantification data to facilities. Where data isn't available, consider collecting information from high-volume facilities that drive consumption. This is important where large numbers of people are expected to be put on treatment in a short time such as in 'Test and Treat' policies. Commodities for patients in care and anticipated to start treatment should be in-country before roll out to avoid stock outs.

## TUPEE480

### INVENTORY MANAGEMENT SYSTEM- LEVERAGING IT BASED PLATFORM TO STRENGTHEN SUPPLY CHAIN: EXPERIENCE FROM INDIA

M. Bamrotiya[1], P. Gupta[2], S. Chaudhury[2], B.B. Rewari[3], S. Kumar[1], A. Sinha[1]
*[1]National AIDS Control Organization, Ministry of Health and Family Welfare, New Delhi, India, [2]Clinton Health Access Initiative, New Delhi, India, [3]WHO India, New Delhi, India*
*Presenting author email: bamrotiya.manish@gmail.com*

**Background:** ART programme in India is currently providing free ART to 919141 PLHIV. Commodities are centrally procured and supplied to 1584 service delivery sites. Diverse geography, varying logistics infrastructure and technology among different states poses challenges to maintain effective supply chain of ARV drugs.
**Description:** In 2013, NACO conceptualized a technology based initiative for improved access to HIV commodities for patients across India. The Inventory Management System (IMS) leverages bar-coding and web-based technologies to introduce an asset light, scalable solution for addressing the supply chain issues. It tracks inventory from supplier to individual patient dispensation in real time. The system has been successfully implemented across all ART centers, State ware houses and Suppliers.
**Lessons learned:** The implementation of IMS at the ART centres has positive impact not only on procurement and supply chain but also on patient management. The system has provided programme more visibility till grass root level.
Consistent usage of IMS across all inventory points, including dispensation has provided significantly improved understanding of inventory requirements across the country. With data on consignment through the inventory points, programme has a better appreciation of constraints faced in logistics and distribution of HIV commodities. Programme is now in the process of optimizing storage space and inventory handling processes to strengthen logistics.
The availability of patient appointment, dispensation and regimens details can be effectively used to predict requirements and recommend effective relocation to minimize losses and wastage. Demand forecasting also can be done more efficiently by developing forecasting algorithms based on inventory classification, rate of consumption, drug criticality and inventory replenishment policies.
The real time visibility to standardized data of 2.1 million patients has been leveraged by programme to get insights into retention cascade analysis, regimen based analysis, treatment effectiveness through adherence analysis, survival analysis, impact on treatment due to patient migration etc.
**Conclusions/Next steps:** To achieve targets of 90-90-90 and ending AIDS as public health threat by 2030, maintaining uninterrupted supply chain and adherence becomes a necessity for any HIV programme. Use of IT based platforms can have a huge impact on resolving issues around supply chain, maintaining and monitoring adherence and patient portability.

## TUPEE481

### BIG DATA ANALYTICS FOR CONTRACT MANAGEMENT: STRENGTHENING MEDICINE SUPPLY SECURITY IN THE WORLD'S LARGEST HIV TREATMENT PROGRAM

G. Steel[1], J. Stokes[1], N. Jagaroo[1], L. Kgomo[1], A. Jezile[1], N. Singh[2], R. Ojageer[2], H. Musariri[2]
*[1]South African National Department of Health, Pretoria, South Africa, [2]Clinton Health Access Initiative, Pretoria, South Africa*

**Background:** The South African National Department of Health (NDOH) manages the suppliers of antiretroviral medicines for the largest antiretroviral therapy programme in the world. The RSA Pharma-Database, a web-based reporting platform,

enables standardised reporting of all transactions from these suppliers. This information is used to generate supplier performance score-cards to inform proactive, remedial contract management actions.

**Description:** In 2013 the NDOH initiated routine contract management meetings with antiretroviral suppliers, creating a platform for transparent communication and problem-solving. This initiative soon expanded to include all pharmaceutical suppliers. The NDOH team identified the need for a standard system with which to measure and report on supplier performance. In support of this initiative, a standard reporting template was developed for suppliers to submit. Monthly reports of all transactions for 11 'clients' on over 1000 line items were submitted in excel from approximately 89 suppliers. These reports were cleaned and collated in a time-consuming manual process.

To address this challenge, in 2014 NDOH developed a web-based system to automate the reporting process. Three supplier score cards were then developed to assess supplier compliance with

a) delivery lead-times,

b) delivery on time in full (OTIF) and

c) reporting requirements.

A composite scorecard was also developed incorporating the three performance measures. Thresholds were developed for each measure by reviewing the distribution of baseline performance.

**Lessons learned:** The standardised performance tools have allowed the contract management team to engage proactively and assertively with pharmaceutical suppliers, both during supplier meetings and in the instance of supply challenges. The use of the scorecards has also resulted in improved co-operation from suppliers, with greater acceptance of responsibility and accountability.

In December 2015 the composite performance scores for the nine contracted antiretroviral suppliers were:

| Poor (Red) | Average (Amber) | Good (Green) |
|---|---|---|
| Three | Five | One |

*[Antiretroviral supplier performance, December 2015]*

**Conclusions/Next steps:** The availability of 'big data' has enabled the implementation of objective supplier performance scorecards. With these tools the NDOH contract management team can engage suppliers proactively regarding poor performance that impacts on medicine availability.

## TUPEE482

### USING MHEALTH TO IMPROVE MEDICINE AVAILABILITY AND SUPPLY CHAIN RESILIENCE: THE CASE OF LOPINAVIR/RITONAVIR

A. Pillay, G. Steel, J. Stokes, N. Mandimika, D. Sandberg, R. Kettledas

*South African National Department of Health, Pretoria, South Africa*

**Background:** The National Department of Health (NDOH) manages the contracted suppliers of antiretroviral medicines for the largest antiretroviral therapy programme in the world. Guided by international recommendations, the NDOH is creating a Visibility and Analytics Network (VAN), to provide end-to-end visibility in the public sector medicine supply chain. The Stock Visibility System (SVS), a mHealth intervention, provides visibility in the 'last mile' of this supply chain and contributes to the overall VAN project. The objective of SVS is to access real-time data regarding medicine availability at primary health care (PHC) clinics. This enables proactive medicine supply management for improved supply chain resilience, and medicine availability.

**Description:** The SVS is a mobile application used to communicate data regarding the availability of antiretroviral and antituberculosis medicines, and vaccines at PHC clinics into a web-based platform. This information can be used in standardised or dynamic reports at National, Provincial and District levels. The SVS project initiated in 2014 and is active in KwaZulu-Natal, Gauteng, Limpopo and Eastern Cape Provinces at 1 249 PHC clinics, servicing an estimated 1,4 million ART patients.

**Lessons learned:** During October-December 2015 NDOH used SVS to respond to nation-wide supply constraints of Lopinavir/Ritonavir. By triangulating stock-on-hand data from SVS with other data sources, 245 priority clinics were identified for expedited direct-deliveries of the limited supply. A hotline number for reporting supply challenges was also disseminated to PHC clinics through SVS. The hotline communicated with 171 clinics in SVS provinces, where any reported supply challenges were resolved within an average of 3.75 days.

**Conclusions/Next steps:** The SVS provided NDOH information to support targeted remedial action in the face of nation-wide supply constraints. It also provided a platform for bi-directional, real-time dissemination of emergency information. In the future SVS will be expanded to all PHC facilities, and monitoring will include all PHC medicines on national contracts. Reports and escalation protocols are under review to improve usability, and acceptability. These changes will improve data availability, and progress towards the realisation of a fully functional VAN. The SVS has contributed directly to improved supply chain resilience and medicine availability.

# STRATEGIES TO IMPROVE UPTAKE AND OUTCOMES IN HIV-INFECTED CHILDREN AND ADOLESCENTS

## TUPEE483

### IMPLEMENTATION OF AN ACTIVE CASE MANAGEMENT NETWORK TO IDENTIFY HIV-INFECTED INFANTS AND ACCELERATE THE INITIATION OF ANTIRETROVIRAL THERAPY, THAILAND 2015

R. Lolekha[1], P. Pavaputanondh[2], T. Puthanakit[3], P. Kosalaraksa[4], W. Petdachai[5], T. Borkird[6], R. Hansudewechakul[7], A. Rojanawiwat[8], S. Boonsuk[9], T. Samleerat[10], H. Thaisri[8], T. Naiwatanakul[1], S. Ongwandee[2], on behalf of the ACC Working Group

*[1]Global AIDS Program Thailand/Asia Regional Office, Thailand Ministry of Public Health-U.S. CDC Collaboration, Nonthaburi, Thailand, [2]Bureau of AIDS, TB and STIs, Ministry of Public Health, Nonthaburi, Thailand, [3]Faculty of Medicine, Chulalongkorn University and HIVNAT, Thai Red Cross AIDS Research Center, Department of Pediatrics, Bangkok, Thailand, [4]Srinagarind Hospital, Khonkaen, Thailand, [5]Phrachomklao Hospital, Petchburi, Thailand, [6]Hatyai Hospital, Songkla, Thailand, [7]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand, [8]Ministry of Public Health, Department of Medical Sciences, Nonthaburi, Thailand, [9]Ministry of Public Health, Department of Health, Nonthaburi, Thailand, [10]Faculty of Associated Medical Sciences, Chiang Mai University, Department of Medical Technology, Chiang Mai, Thailand*

**Background:** Early initiation of antiretroviral therapy (ART) among HIV-infected infants can reduce HIV/AIDS associated morbidity and mortality. In Thailand in 2012, only 52% of HIV-infected infants received ART in the first year of life. We implemented a National Active Case Management (ACC) Network to promote early ART initiation in August 2014.

**Methods:** Thailand's 2014 HIV Treatment Guidelines recommend that HIV-exposed infants have HIV PCR testing at birth, 1 and 2-4 months. When an HIV-infected infant (HIV PCR+) is identified, lab staff sends the result to the hospital. In addition, as part of the ACC, lab staff alert a regional case manager (CM) who contacts hospital staff to provide technical support, ensure prompt ART initiation, and support ART adherence among HIV-infected infants and mothers. We analyzed national data collected on HIV-infected infants by the ACC Network.

**Results:** During August 2014-December 2015, 101 infants had at least one positive HIV PCR. Mean age at first positive PCR was 93 days (range: 0-424) and 60 (59%) were female. Thirteen (13%) had a positive PCR result at birth; mean age 2.5 days (range: 0-8), and 88 (87%) had a positive result at other visits; mean age 106 days (range: 26-424). Among the 101 infants, 83 (82%) had received ART as of December 2015; 19 (23%) started ART before 2 months, 67 (81%) before 6 months, and 79 (95%) before one year of age. Among 18 infants not receiving ART, 9 (50%) died, 6 (33%) lost to follow-up, and 3 (17%) were diagnosed HIV infection in December 2015. Mean age at ART initiation was 31 days (range: 15-52) for those HIV PCR positive at birth, and 129 days (range: 35-465) for those HIV PCR positive at other visits. The mean time from blood collection to notification of a regional CM about the positive result was 16 days (range: 0-41) and from notification of the CM until the infant started ART was 15 days (range: 0-140).

**Conclusions:** The ACC network has been successfully established and initial results suggest the Network is promoting early ART initiation. This Network may be adaptable to other settings.

## TUPEE484

### INDEX CASE FINDING INITIATIVE FACILITATES IDENTIFICATION AND LINKAGE TO CARE OF CHILDREN AND YOUTH LIVING WITH HIV/AIDS

R.A. Sabelli[1], M.H. Kim[1,2], K. Simon[1,2], E. Kavuta[1], M. Harawa[1], S. Dick[1], F. Linzie[3], P.N. Kazembe[1,2], S. Ahmed[1,2]

*[1]Baylor College of Medicine Abbott Fund Children's Clinical Center of Excellence, Lilongwe, Malawi, [2]Baylor International Pediatric AIDS Initiative at Texas Children's Hospital, Baylor College of Medicine, Houston, United States, [3]Malawi Ministry of Health, Lilongwe, Malawi*

*Presenting author email: rachaelsabelli@gmail.com*

**Background:** Less than a quarter of children with HIV in low- and middle-income countries are receiving lifesaving HIV treatment. Identification of children and youth remains a significant barrier to improving access and increasing coverage. We evaluated the impact of a novel family-centered, index case finding strategy to identify and link HIV-infected children/youth aged 1-24 years to care.

**Methods:** The program was implemented July 2014 to April 2015 at Mponela Rural Hospital, a government-funded facility in Malawi. HIV-infected patients (index cases) enrolled in HIV services at the facility were screened, and those who reported untested household members were offered home or facility-based HIV testing and

counseling (HTC) by a community health worker (CHW). Household members found HIV-infected were enrolled in a follow-up program offering one-on-one home and facility-based follow-ups by CHWs.
**Results:** There were 461 (44.8%; 461/1030) index cases who reported untested household members, of which 431 (93.5%) consented to household HTC. Of these index cases, 140 (32.5%) were male, median age (IQR) was 37 (36.2-38.5), 264 (65.5%) were on antiretroviral treatment (ART) for more than one year, and 279 (64.7%) reported an untested child/youth. CHWs newly diagnosed 28 (yield 4.0%; 28/711) HIV-infected children/youth and identified an additional two HIV-infected not in care. Characteristics of tested children/youth are shown in the table.

| Characteristic | 1-9 years (n=339 (%)) | 10-24 years (n=372 (%)) | Total 1-24 years (n=711 (%)) |
|---|---|---|---|
| **Location of Test** | | | |
| Home-Based | 320 (94.4) | 359 (96.5) | 679 (95.5) |
| Facility-Based | 19 (5.6) | 13 (3.5) | 32 (4.5) |
| **Gender, Male** | 182 (53.7) | 165 (44.4) | 347 (48.8) |
| **Mean age, years (IQR)** | 5 [illegible] | 15 [illegible] | 11 (10.5-11.4) |
| **Relation to Index** | | | |
| Biological Child | 219 (64.6) | 171 (46.0) | 390 (54.8) |
| Sibling | 13 (3.8) | 17 (4.6) | 30 (4.2) |
| Spouse | 0 (0.0) | 9 (2.4) | 9 (1.3) |
| Other | 107 (31.6) | 175 (47.0) | 282 (39.7) |
| **Rapid Test Result** | | | |
| Positive | 15 (4.4) | 13 (3.5) | 28 (3.9) |
| Negative | 323 (95.3) | 357 (96.0) | 680 (95.6) |
| Inconclusive* | 1 (0.3) | 2 (0.5) | 3 (0.4) |

*Inconclusive: [illegible]

*[Table: Characteristics of children and youth HIV tested aged 1-24 years]*

Of the 30 identified, 23 (76.6%) enrolled into HIV services and 18 (90%; 18/20) of those eligible started ART. Median time (IQR) from identification to enrollment into HIV services was 4 days (2.6-18.7) and from identification to ART start was 6 days (2.5-23.1).
**Conclusions:** Our study demonstrates that almost half of HIV-infected patients enrolled in treatment services have untested household members. A family-centered, index case finding approach, coupled with home-based testing and tracked follow-up is acceptable and feasible, and facilitates the identification and timely linkage to care of HIV-infected children and youth.

## TUPEE485

### REMINDING ADOLESCENTS TO ADHERE: ONE-YEAR RESULTS FROM A RANDOMIZED TRIAL OF TEXT MESSAGING FOR IMPROVING ART ADHERENCE

S. Linnemayr[1], H. Huang[2], B. Mukasa[3], A. Kambugu[4], G. Wagner[5]
*[1]RAND Corporation, ESS, Los Angeles, United States, [2]RAND Corporation, Pardee RAND Graduate School, Santa Monica, United States, [3]Mildmay Uganda, Kampala, Uganda, [4]Infectious Diseases Institute, Kampala, Uganda, [5]RAND Corporation, Health, Los Angeles, United States*
*Presenting author email: slinnema@rand.org*

**Background:** The rapid adoption of mobile phones in low-income countries has made SMS a low-cost and scalable tool for health providers to remind/encourage patients to take their medications. While two studies show positive effects of SMS reminders for adherence to antiretrovirals (ART) among adults, the approach has not been tested for youth. In this study, we investigate whether SMS messages improve adherence to ARTs among HIV-positive Ugandan youth, and whether the option of responding to the messages (as opposed to just receiving them) has an added effect.
**Methods:** Starting in April 2014, 332 youth between ages 15-22 in two HIV care facilities in Kampala were randomized into three groups: control, treatment 1 (reminder message only) and treatment 2 (reminder + response option). We use 1 year of adherence data measured using Medication-Event-Monitoring Systems (MEMS) caps, in an intent-to-treat analysis using adherence measures established in the previous literature to allow for comparability with the existing studies.
**Results:** We find no difference in adherence across the treatment and control groups. Mean adherence is 72.1% [95 CI: 67.6, 76.5] for control, 69.9% [95 CI: 65.0, 74.7] for treatment 1, and 71.0% [95 CI: 66.5, 75.5] for treatment 2, with no statistically significant difference across the three categories (p=0.81). 34.6% [95 CI: 30.3, 38.8] of participants in the sample have adherence over 90%, with no statistical difference between groups (p=0.98). Similar results hold when we adjust means for baseline covariates that may be associated with adherence. Furthermore, we find no differential impact by socioeconomic status and age, which we hypothesized to be associated with greater mobile phone use.
**Conclusions:** As SMS is increasingly becoming a popular tool for health practitioners to encourage healthy behaviors, it is critical to assess its effectiveness for different populations, which may have different barriers to adherence and levels of engagement with technology. This study provides evidence that - contrary to the promising results in the literature for adults - standard text messaging did not significantly improve adherence to ART for youth, suggesting the importance of careful targeting of such interventions, and adopting them to address perceived needs of recipients.

*Presenting author email: valeriane.leroy@inserm.fr*

**Background:** We performed a global analysis of the pre-ART retention cascade of HIV-infected children from HIV diagnosis to antiretroviral therapy (ART) initiation within the IeDEA network, from 2004 to 2014.
**Methods:** We pooled data from cohorts of the IeDEA network in the Asia-Pacific, sub-Saharan Africa, and Latin America. We included all HIV-1 infected children, aged 0-19 years and ART-naïve at enrolment into HIV programs. We described the proportions of children initiating ART and the missed opportunities for ART initiation (death, loss to follow-up [LTFU], transfer) since program entry: enrolment or date of confirmed HIV diagnosis if this occurred second. We computed the cumulative incidence functions (CIF) for ART initiation and analysed the determinants, accounting for death and LTFU as competing risks until 24 months.
**Results:** Among the 115,549 children included, 78,374 initiated ART (67.8%), 2.0% died, 4.5% were transferred-out, and 20.8% were LTFU before ART initiation. The 24-month CIF for ART initiation per region was 52.0% (95% Confidence Interval [CI]:50.6-53.3) in Central-Africa, 57.8% (CI:57.1-58.5) in East-Africa, 60.6% (CI:59.5-61.7) in West-Africa, 66.7% (CI:66.4-67.1) in Southern-Africa, 76.2% (CI:74.8-77.6) in the Asia-Pacific, and 76.9% (CI:74.4-79.2) in Latin-America. Median age at ART initiation varied across regions: 5 years in the Asia-Pacific and West-Africa, 7 years in East-Africa and Southern-Africa, 8 years (IQR:3-16) in Latin-America, and 10 years (IQR: 5-15) in Central-Africa (p< 0.01). Median CD4% at ART initiation varied from 10% in the Asia-Pacific, 13% in West-Africa, 14% in Central-Africa, East-Africa, and Southern-Africa, to 15% in Latin-America (p< 0.01). Children aged 15-19 years and those aged < 1 year were those with the lowest ART initiation rates compared to other ages, with an overall CI of ART initiation of 54.3% (95%CI:53.6-55.0) and 61.4% (95%CI:60.6-62.1), respectively. In the adjusted analysis, girls, all regions compared to Latin-America, ages< 10 years and >15 years, enrolled< 2010, low-middle income countries, and CD4≥500 cells/µL were less likely to initiate ART.
**Conclusions:** In 2014, many obstacles to ART initiation remain with substantial inequities. Girls and those at the youngest and oldest ends of the paediatric age spectrum need more effective and targeted interventions to improve their access to ART initiation.

## TUPEE487

### THE IMPACT OF INCENTIVES ON UPTAKE OF HIV TESTING AMONG ADOLESCENTS IN A HIGH HIV PREVALENCE SETTING

S. Dakshina[1], T. Bandason[2], E. Dauya[2], K. Kranzer[3], G. Mchugh[2], S. Munyati[2], P. Chonzi[4], R. Ferrand[3]
*[1]Barts Health NHS Trust, Sexual Health and HIV Medicine, London, United Kingdom, [2]Biomedical Research and Training Institute, Harare, Zimbabwe, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Harare City Health, Harare, Zimbabwe*
*Presenting author email: subadak@yahoo.com*

**Background:** Adolescents face substantial barriers in accessing HIV testing and nearly 70% of HIV-infected adolescents are undiagnosed. Incentivised testing has shown to increase uptake of HIV testing in marginalised groups. We investigated the impact of incentives on HIV testing uptake in adolescents aged 8-17 in Harare, Zimbabwe.
**Methods:** This study was nested within an anonymised community-based HIV prevalence survey. Households with children aged 8-17 years who had not previously undergone HIV testing were referred to primary healthcare clinics for diagnostic HIV testing. Participating households were randomised to receiving nothing (standard of care) or to either enter a prize draw (USD 10, USD 5 or nothing, probability of

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

picking 0.06, 0.07, 0.9, respectively) or receive USD 2 if they accessed diagnostic HIV testing. HIV testing was carried out with guardian consent for those aged < 16 years and participant assent. Uptake of HIV testing was compared across the three groups.
**Results:** A total of 2841 children (79% of all eligible) from 2050 selected households participated. Median age was 12 (IQR 10-15) years and 53% were female. Of those eligible 98% (2796) were referred for diagnostic HIV testing, and of these 35.7% attended for testing.

| | SOC | USD2 | Prize draw |
|---|---|---|---|
| Households randomised | 649 (32%) | 740 (36%) | 661 (32%) |
| Children randomised* | 735 (26%) | 1155 (41%) | 906 (32%) |
| Attended clinic | 110 (15%) | 554 (48%) | 336 (37%) |
| Diagnosed positive | 0 | 4 (0.3%) | 7 (0.8%) |

*[Summary of results]*

*All children aged 8-17 years in a selected household were eligible
**Conclusions:** Overall uptake of HIV testing remained low but significantly more adolescents underwent HIV testing when monetary incentives were offered. Our findings show that incentives may be an effective strategy to improve uptake of HIV testing. These need to be combined with efforts to engage adolescents and their guardians.

## TUPEE488

### ADDRESSING SUPPLY-SIDE BOTTLENECKS TOWARDS 90-90-90 TARGETS FOR PEDIATRIC HIV IN WESTERN AND CENTRAL AFRICA REGION (WCAR): A MULTI-COUNTRY SITUATION ANALYSIS (2014-2015)

L. Tsague[1], E. Nyankesha[1], A. Bacha[1], A. Bollinger[1], M. Oulare[2], D. Chamla[3], C. Kamenga[1]
*[1]UNICEF, Programme, HIV&AIDS, Dakar, Senegal, [2]UNICEF Ethiopia, Addis-ababa, Ethiopia, [3]UNICEF-HQ, New-York, United States*
*Presenting author email: ltsague@gmail.com*

**Background:** Only 13% of children under 15 years living with HIV were receiving ART in 2014 in West and Central Africa Region (WCAR). To identify bottlenecks to pediatric ART, we conducted a multi-country assessment of the program's enabling environment, supply and demand-side bottlenecks. We report on the supply-side bottlenecks and programmatic implications.
**Description:** : During 2014-2015, data collection was conducted in 11 WCAR countries (Cameroon, Congo, Cote d'Ivoire, Gabon, Ghana, Guinea-Bissau, Liberia, Nigeria, Democratic Republic of Congo (DRC), Chad, and Togo) using standardized tools. We applied the Tanahashi framework to identify program bottlenecks across the cascade of comprehensive pediatric HIV programming (case-identification; linkages and ART initiation; retention and transition). Data collection included key informant interviews and data abstraction from registers in a sub-sample of purposively selected health facilities.
**Lessons learned:** A total of 399 health facilities were surveyed in 11 countries. Coverage of early infant HIV diagnosis (EID) services ranged from 1.0% in Chad to 35.4% in Cameroon. Proportion of ART sites providing pediatric ART ranged from 2% in Chad to 56% in Togo. PMTCT was the main entry point for early pediatric HIV case identification (99.5% of all DBS samples in Togo and 93.5% in Ghana). Median turnaround time for EID ranged from 2.2 months in DRC to 3.5 months in Ghana. Coverage of PCR machines was inadequate in most countries (from none in Liberia and Guinee Bissau to 23 in Nigeria). Assessment of final HIV-status at 18 months ranged from 24% in Ghana to 41% in Nigeria. Lack of pediatrics HIV integration within routine Child Health services
(e.g. immunization and hospitalization), adult ART treatment program were reported.
**Conclusions/Next steps:** Low service coverage (both diagnosis and treatment) and lack of integration pediatric HIV interventions into routine MNCH services seem to be the major bottlenecks to pediatric ART. PMTCT remains the main entry point for pediatric HIV case-identification with poor retention by 2 years. Based on these findings, countries' National Pediatric HIV programs are prioritizing pediatric HIV case-finding beyond PMTCT/EID entry points to optimize the yield, while increasing availability of quality ART services through decentralization, task-shifting and linkages with care and support interventions at community level.

## TUPEE489

### ACCELERATING PEDIATRIC HIV CARE AND TREATMENT IN COTE D'IVOIRE FROM LESSON LEARNED TO ACTION PLAN

N. Daries[1], D. Glohi[2], M. Kone[1], L. Tsague[3], A. Kwagny[2], E. Nyankesha[3]
*[1]UNICEF, Abidjan, Cote D'Ivoire, [2]Ministry of Health and Hygiene, Abidjan, Cote D'Ivoire, [3]UNICEF Regional Office, Dakar, Senegal*
*Presenting author email: ndaries@unicef.org*

**Background:** In 2014, 40,000 children aged 0 - 15 were estimated to be living with HIV in Cote d'Ivoire. Pediatric ART coverage was very low at 18% while adult ART was at 76%. Identify and analyze the bottlenecks of the HIV pediatric program to design an acceleration plan to improve access to ART for children living with HIV in Cote d'Ivoire.
**Description:** A cross-sectional survey was conducted in 2015 to collect data and information related to the management of pediatric HIV program with a participatory evaluation. The survey covered the three levels of the health pyramid with 28 facilities (3 tertiary hospitals, 12 general hospitals and 14 health centers). An analysis of the survey data was done using SPSS software.
**Lessons learned:** The number of children on ART has slowly increased from 5,190 in 2010 to 6,932 in 2014. Access to Early Infant Diagnosis (EID) is low with 33% of facilities offering PMTCT services providing DBS sample collection for EID and 3 laboratories performing the PCR test but located in the capital city, Abidjan. Pediatric ART services is limited to 43 % of all PMTCT sites. In the sample of health facilities surveyed, a total of 4,172 children living with HIV were registered in care with only 2,900 (69.5%) on ART. Retention in care at 12 months among children on ART was estimated at 59%. Over two thirds of these children (70%) were followed at tertiary level. Main bottlenecks linked to HIV Pediatric program identified were low decentralization of EID, and pediatric ART, lack of qualified trained health workers, limited integration of pediatric HIV case-findings in other **entry points** than EID/PMTCT.
**Conclusions/Next steps:** The low coverage of Pediatric ART in Cote d'Ivoire is likely due to limited service coverage (both diagnosis and treatment) and lack of integration of pediatric HIV interventions into routine MNCH services. The country is developing an acceleration plan that will prioritize task shifting and decentralization of EID and ART services, while optimizing case-finding of children (< 15 years) through high yield entry points (adult ART program, malnutrition, immunization, hospitalization and tuberculosis program) and engaging parents and communities to improve the performance.

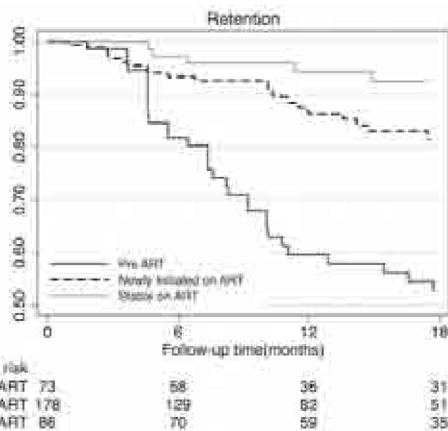
## TUPEE490

### YOUTH ART ADHERENCE CLUBS: OUTCOMES FROM AN INNOVATIVE MODEL FOR HIV-POSITIVE YOUTH IN KHAYELITSHA, SOUTH AFRICA

L. Wilkinson[1], F. Moyo[2], R. Henwood[2], P. Runeyi[2], S. Patel[3], V. de Azevedo[3], P. Tsondai[4], A. Grimsrud[5]
*[1]Médecins Sans Frontières, University of Cape Town, Centre for Infectious Disease Epidemiology & Research, School of Public Health & Family Medicine, Cape Town, South Africa, [2]Médecins Sans Frontières, Cape Town, South Africa, [3]City of Cape Town Health Department, Cape Town, South Africa, [4]University of Cape Town, Centre for Infectious Disease Epidemiology & Research, School of Public Health & Family Medicine, Cape Town, South Africa, [5]International AIDS Society, Cape Town, South Africa*
*Presenting author email: lynneswilkinson@yahoo.com*

**Background:** Retaining youth, both anti-retroviral treatment (ART) ineligible and those on ART, remains challenging with higher rates of loss to follow-up (LTFU) than their adult counterparts. Adjusting the ART adherence club model for youth, enrolling ART ineligible youth to expose them to peers on ART and integrating family planning (FP), may address this challenge.
**Methods:** From March 2012-May 2015 HIV positive youth at a youth clinic (12-25 years old) were enrolled in Youth Clubs (YCs). Those ART-ineligible, newly initiated and stable on ART were combined in groups of ~20. Separate groups were formed for younger school attending and older youth. YCs were facilitated by a lay counsellor with structured session guides. ART supply, FP and HIV clinical management were integrated within the model. We conducted a retrospective cohort analysis with LTFU defined as no YC or clinic contact from June-August 2015. We describe characteristics and retention outcomes using Kaplan-Meier methods stratified by enrolment category.
**Results:** 337 youth (21.7% ART-ineligible, 52.8% newly initiated and 25.5% stable on ART) enrolled in YCs contributing 414.8 person years to the analysis [median 1.2, interquartile range (IQR) 0.5-1.9]. The majority were female (85.76%) with median age at YC enrolment of 22.3 years (IQR 20.3-23.7). 58 (17.2%) attended school clubs. Overall retention at 12-months was 81.7% [95% confidence interval (CI) 76.4-86.0] and varied by enrolment category (p-value< 0.001): 52.9% (95% CI 40.0-64.2) ART-ineligible, 86.4% (95% CI 78.7-91.4) newly initiated and 94.3% (95% CI 85.4-96.8) stable on ART (Figure 1). Over the study period, 1 (3%) died, 101 (30.0%) transferred

out (60 of whom graduated to adult care), and 71 (21.1%) were LTFU. 18 initiated ART and 84 became stable on ART.



*[Retention 18m KM]*

**Conclusions:** The YC model supported high rates of retention among young adults on ART. ART ineligible youth remained difficult to retain despite integration into groups with youth on ART.

## TUPEE491

### DEPRESSION, ANTIRETROVIRAL THERAPY (ART) ADHERENCE (BY PARENTAL REPORT AND PLASMA ANTIRETROVIRAL LEVELS), AND ART RESPONSE IN YOUTH ENROLLED IN THE ADAPTED BLASINI DISCLOSURE INTERVENTION (ABDI) IN HAITI AND DOMINICAN REPUBLIC

K. Loubeau[1], R. Abreu-Perez[2], L. Lerebours-Nadal[3], C. Beck-Sague[4], M.C. Pinzon-Iregui[4], J. Devieux[4], A. Dean[5], R. Wang[6], I. Blasini[7], S. Nicholas[3,8], J.W. Pape[1,9]

*[1]Groupe Haitien d'Etude du Sarcome de Kaposi et des Infections Opportunistes (GHESKIO), Port-au-Prince, Haiti, [2]Robert Reid Cabral Children's Hospital, Teofilo Gautier Comprehensive Care Center, Santo Domingo, Dominican Republic, [3]Clinica de Familia La Romana, La Romana, Dominican Republic, [4]Florida International University, Robert Stempel College of Public Health and Social Work, Miami, United States, [5]University of Miami, Miami, United States, [6]University of North Carolina at Chapel Hill, Clinical Pharmacology & Analytical Chemistry Laboratory (CPAC), Chapel Hill, United States, [7]University of Puerto Rico, Dept. of Pediatrics, San Juan, Puerto Rico, [8]Columbia University, IFAP Global Health Program, College of Physicians & Surgeons, New York City, United States, [9]Weill Cornell Medical College, New York City, United States*

*Presenting author email: krystel.loubeau@gmail.com*

**Background:** Disclosure of their HIV status to perinatally HIV-infected (PHIV) youth is important for transition to independent living, ART adherence and prevention of further HIV transmission. Worldwide, however, few PHIV youth know their status. To assess the impact of structured disclosure using aBDI in PHIV ART patients in Haiti and Dominican Republic (DR), outcomes were compared pre- and post-disclosure in aBDI "completers", and to outcomes in youth who discontinued aBDI participation before disclosure.

**Methods:** Data on depression symptoms using the Child Depression Inventory (CDI) and on ART adherence were collected in one-on-one interviews with 10.0-17.8 year-old non-disclosed youth and their caregivers at enrollment and 3-6 months post-disclosure in three centers (one DR children's hospital and one DR and one Haiti center serving patients of all ages). Plasma efavirenz, nevirapine or lopinavir levels were quantified at enrollment and post-disclosure. Viral load and CD4 count measurements were collected by medical record review at enrollment and 3-6 months post-disclosure (in aBDI "completers") or post-aBDI discontinuation.

**Results:** Of 115 caregiver/youth pairs enrolled, 93 (80.9%) accepted disclosure and were assessed post-disclosure; 22 declined disclosure ("aBDI discontinuation"). At enrollment, 23.3% of youth (34.9% of Haitian, 15.0% of DR youth [P=.02]) met CDI depression criteria. Median viral loads pre- and post-disclosure were higher in youth with sub-therapeutic than those with therapeutic antiretroviral levels (15,509 copies/ml versus < 40 copies/ml; P< .0001), and in youth whose caregivers reported missed doses during the last month than in others (8,614 copies/ml versus 49 copies/ml, P=.04), but did not differ by "perfect" adherence. Depressed youth had higher viral loads (median=5,560 copies/ml) and lower CD4 counts (median=480 cells/mm$^3$) than non-depressed youth (median < 40 copies/ml, P=.049; median=608 cells/mm$^3$; P=.089). Among youth who completed aBDI, depression prevalence was lower post-disclosure (13.4%) than at enrollment, not differing significantly by country (14.3%, Haiti; 12.8%, DR). Median viral load tended to be higher post-aBDI discontinuation than post-disclosure (790 copies/ml versus < 40 copies/ml; P=.19, NS); this difference was statistically significant only in participants in the two non-pediatric centers (38,533 versus 195 copies/ml; P=.016).

**Conclusions:** aBDI completion may be associated with decreased depression and improved viral suppression in pediatric ART patients.

## TUPEE492

### ADDRESSING THE LOW COVERAGE OF PEDIATRIC ART IN TOGO: FINDINGS FROM A NATIONAL SITUATION ANALYSIS, 2014

F. Agbeko[1], O. Tchagbele[1], K.A.R. Segbedji[2], M. Fiawoo[1], K.E. Djadou[1], Y. Atakouma[1], K.D. Azoumah[2], Z. Adam[3], A. Singo[3], K. Abalo[4], E. Nyankesha[5], D.L. Tsague[5], C. Kamenga[5]

*[1]Sylvanus Olympio Teaching Hospital of Lome, Pediatry, Lome, Togo, [2]Teaching Hospital of Kara, Pediatry, Kara, Togo, [3]Ministry of Health, National AIDS Control Programme (PNLS), Lome, Togo, [4]Unicef Togo, Lome, Togo, [5]UNICEF - WCARO, Dakar, Senegal*

*Presenting author email: folyvon@gmail.com*

**Background:** In Togo, there is still a wide gap in access to antiretroviral therapy (ART) between children (16%) and adults (45%). We assessed barriers to pediatric ART in view of informing strategic priorities towards 90-90-90 for children in Togo.

**Methods:** We applied the following pediatric ART program pillars: case identification, linkages and ART initiation, retention and transition. Within each pillar, we assessed gaps, and explored when applicable the barriers related to enabling environment, supply-side, demand-side, and quality of care and treatment services. Standardized questionnaire was used to abstract qualitative and quantitative data. To assess children's outcomes on ART and quality of care, we abstracted data from 26 health facilities purposively sampled from all six regions. Strategic priorities were identified during a validation workshop.

**Results:** Nationally, in 2013, less than 14% of infants exposed to HIV were tested for HIV within their first two months of life. Children (0-14 years) represented 4% of the 254,199 HIV tests registered. Early infant HIV diagnosis (EID) was limited to 28% of the 864 MCH facilities, while routine provider-initiated HIV testing and counseling among sick children and adolescents was performed in only 20 out of 864 MCH facilities. Only 56% of 250 ART health facilities were providing pediatric HIV treatment. In the 26 sites surveyed, children represented 9.4% of all patients on ART. Compliance with national treatment protocols was 100%. Average age at ART initiation was 99 months and 24-month survival on ART was estimated at 61% pointing to late identification and initiation of treatment. Shortage of trained staff for HIV testing and ART management, frequent stock-outs of HIV test kits, limited geographic availability of pediatric ART centers, and complex procedures for enrollment in ART programme were identified as major bottlenecks.

**Conclusions:** Increasing geographic coverage of pediatric HIV testing, care and treatment services is a strategic priority to fast-tract pediatric ART coverage. Scaling-up integration of pediatric HIV case-finding into child care (immunization and hospitalization) and into adult ART program is critical. Strengthening task shifting for ART initiation and improving retention in care are additional priorities.

## TUPEE493

### REACHING OUT TO CHILDREN OF PEOPLE LIVING WITH HIV/AIDS WITH HIV TESTING, CARE AND TREATMENT: PRELIMINARY RESULTS OF THE ACTIVE SEARCH FOR PEDIATRIC HIV/AIDS (ASPA) STUDY IN CAMEROON

H.A. Yumo[1,2], R.A. Ajeh[2], M. Beissner[3], I. Sieleunou[2,4], M.N. Akindeh[2,5], P.B. Kuwoh[6], D. Addison[7], A.A. Adedimeji[8], D. Nash[7], K. Anastos[8,9], C. Kuaban[10], T. Loescher[3], ASPA Study Group

*[1]Center for International Health, Ludwig Maximilians University, Department of Infectious Diseases, Munich, Germany, [2]R4D International, Yaounde, Cameroon, [3]Ludwig Maximilians University, Department of Infectious Diseases, Munich, Germany, [4]University of Montreal, School of Public Health, Montreal, Canada, [5]University of Yaounde I, Yaounde, Cameroon, [6]Limbe Regional Hospital, Limbe, Cameroon, [7]City University of New York, Hunter College School of Public Health, New York, United States, [8]Albert Einstein College of Medicine, Department of Epidemiology & Population Health, New York, United States, [9]Montefiore Medical Center, New York, United States, [10]University of Bamenda, School of Health Sciences, Bamenda, Cameroon*

*Presenting author email: ha.yumo12@gmail.com*

**Background:** The World Health Organization (WHO) recommends index case HIV testing as a priority approach to increase uptake of HIV testing amongst children of people living with HIV/AIDS (PLHW). We assessed the acceptability, feasibility and yield of this strategy in a health facility in Cameroon.

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

**Methods:** From July 2015 to December 2015, we invited PLHW receiving care in the Limbe Regional Hospital (South West-Cameroon) and having children aged 6 weeks to 19 years to participate in the ASPA study. Consenting parents were enrolled in the study together with their children. Socio-demographic data were collected and HIV testing was provided for children with unknown HIV status either in the hospital or at home.
**Results:** All of the 327 eligible parents agreed to enrol in the study, the majority (78.9%) were females and the age ranged from 20 to 58 years with a median of 39 years. Almost all (96.3%) parents were on ART. Altogether, parents reported 696 children below the age of 19 years, of those only 253 (36.3%) had ever been tested for HIV prior to the study and 8 (3.1%) of them tested HIV positive. All parents (n= 231) having children with unknown HIV status accepted to have their children tested and the large majority (93.3%) preferred the hospital as testing site. Amongst children with unknown HIV status (n=437), the study was able to test 302 (69.1%) and 5 (1.6%) of them tested HIV positive. Reasons for failure to test all children with unknown HIV status included: missing consent of one parent to test their child, fear of disclosure, lack of time by parents to bring children to the hospital, lack of transportation means to the hospital, children going to school or living elsewhere.
**Conclusions:** Although the acceptability of the index HIV testing strategy for children was high amongst PLHIV, the feasibility of this active case finding approach is challenged by several barriers. There is need to elucidate these obstacles through qualitative research and address them accordingly in order to optimize the implementation of this strategy.

## Partnerships involving donors, NGOs, and government

### TUPEE494

#### Improving access and ensuring health rights for key populations by setting up a technical support unit for key populations by Ministry of Health, Government of Kenya

J. Anthony[1], H. Musyoki[2], B. Ogwang[3], S. Kaosa[3], M. Sirengo[2]
*[1]University of Manitoba, Technical Support Unit, Nairobi, Kenya, [2]Ministry of Health, National AIDS and STI Control Program, Nairobi, Kenya, [3]Partners for Health and Development in Africa, Technical Support Unit, Nairobi, Kenya*
*Presenting author email: john.anthony@ihat.in*

**Background:** Key populations (KPs) contribute 33% (MOT 2008) of 100,501 (NACC 2014) new HIV infections. HIV prevalence rates among female sex workers (FSW), Men having sex with men (MSM) and people who inject drugs (PWIDs) is 29.3 %, 18.2 % and 18.3 % respectively (NASCOP 2013). In resource-limited settings, Government structures fell short in providing technical support to programs as they were overstretched across multiple priorities and lacked human resources in capacity and numbers.
**Description:** Through Private-Government partnership, a Technical Support Unit (TSU) was set up in 2012 within Ministry of Health (MoH), Government of Kenya to support MoH in delivering effective and efficient HIV prevention programs for KPs. The TSU conducted a national mapping of KPs, field program improvement visits of more than 1500 days in 33 counties where KP programs exist, in 82 partner locations. National KP implementation guidelines were developed, KP population forums were established and friendly microplanning and outreach services were put in place. TSU set up a KP reporting system to cover all implementing partners across country.
**Lessons learned:** KP program reporting increased from zero to 100% (September 2015). Quarterly outreach contacts increased from 33% to 78% among FSWs, 32% to 78% among MSMs and 54% to 70% among PWIDs during 2013-2015. Similarly, quarterly HIV Counselling and testing also increased from 12% to 35% among FSWs, 10% to 32% among MSMs and 17 to 23 % among PWIDs. Screening services improved from 14% to 33% among FSWs, 9% to 33% among MSMs and 6% to 27% among PWIDs. STI positivity dropped from 21% to 8% for FSWs, 22% to 11% for MSMs and 17 % to 4% for PWIDs during the same period. This was achieved against the national program targets covering 142,529 FSW, 16,227 MSMs and 11,415 PWIDs.
**Conclusions/Next steps:** Embedding TSUs within Government structures improves efficiency and effectiveness of KP programming and provides in house quality managerial and technical talent. As Kenya AIDS Strategic Framework (2014-2019) is being implemented, the role of TSUs will be vital in maintaining the intensity of KP programming and contribute in halting and reversing the epidemic in Kenya.

### TUPEE495

#### Early lessons learnt from monitoring and evaluation of the medicine donation program in the New Horizons Pediatric HIV Care Collaborative

C. Vail[1], U. Maraj De Villiers[2], C. Ruffell[3], K. Manson[4], on behalf of the New Horizons Collaborative
*[1]Janssen Global Services, LLC, Raritan, United States, [2]Johnson and Johnson, Woodmead, South Africa, [3]Janssen South Africa, Woodmead, South Africa, [4]Janssen-Cilag Ltd, High Wycombe, United Kingdom*
*Presenting author email: umarajde@its.jnj.com*

**Background:** The New Horizons Advancing Pediatric HIV Care Initiative is a collaborative effort of Janssen, Elizabeth Glaser Pediatric AIDS Foundation, Partnership For Supply Chain Management, Imperial Health Sciences (IHS), and others to enhance access to sustainable and appropriate HIV care for treatment-experienced children and adolescents in sub-Saharan Africa and least-developed countries. Currently Swaziland, Zambia, Kenya, Lesotho, and South Africa are participating, after an Expression-of-Interest and selection process.
One component is a medicine donation program for PREZISTA™ (darunavir) and INTELENCE™ (etravirine). To avoid conflict with the national health systems, the donation is distributed through the respective national HIV/AIDS distribution channels.
As emphasized in the WHO Guidelines for Medicine Donations, regular monitoring and evaluation (M&E) of the program is an essential component within the New Horizons Initiative (NHI). A summary of the evaluation approach is provided here along with challenges and opportunities identified during early implementation.
**Description:** A unique framework has been developed to ensure that the logistical process and the M&E procedures are in line with the following guidelines: WHO Guidelines for Medicine Donations, Good Distribution Practices for Pharmaceutical Products, Good Storage Practices, Good Transportation Practices, Good Pharmacy Practice. A simple one-page M&E tool was designed for the NHI program based on these guidelines and additional efficiency measures have been included.
First M&E assessments were undertaken in 2015: in Kenya, Zambia, and the interim warehousing in South Africa by IHS.
**Lessons learned:** All recipient countries were actively engaged in the M&E process. The framework was beneficial in better understanding recipient and donor challenges and collaboratively developing necessary remediation or continuous improvements.
While different challenges were described in each country, some common opportunities for improvement were: forecasting and quantification of medicine needs, clearing customs, temperature monitoring and cooling, patient confidentiality, providing sufficient storage space, and managing shipment packing lists.
**Conclusions/Next steps:** Overall, M&E proves essential in shaping and reinforcing relationships between stakeholders thus strengthening the collaborative program. The New Horizons medicine donation M&E framework revealed opportunities and enabled partners to develop shared tools and individual action plans. Shared tools included a forecasting quantification tool and a utilization tool.

### TUPEE496

#### Leveraging-off existing programs to deliver services to broader communities: a case of a rural school-based sexual reproductive health and rights program in South Africa

N. Shaikh, A. Grimwood, Z. Ncama, G. Fatti, E. Mothibi
*Kheth'Impilo, Cape Town, South Africa*
*Presenting author email: shaikh.bhorat@gmail.com*

**Background:** Youth and their households living in high HIV-prevalence areas often experience deprivation at multiple levels such as geographic, education, economic, health and basic human-rights. Improving access to social protection services can mitigate the impact of the HIV epidemic as well contribute to strengthening HIV prevention and care among marginalised groups.
**Methods:** As part of the school-based clinic-linked SRH&R program implemented by KhethImpilo, a school-end initiative involving various partners, mobilized to deliver a one-day Health and Welfare jamboree. Learners, educators and the broader community were invited to participate in a school cultural program Adolescent-Friendly Primary health Clinic. The SRH&R activities involved debates, dances, poetry and plays simultaneously with 14 services providers onsite to screen, educate, and treat with service-referral. Program staff together with various partners coordinated the logistics. Uptake of services was tracked through data registers at each service point measuring, age, gender, type of service accessed. Qualitative data was collected through interviews and video clips.
**Results:** The SRH&R Jamboree involved learners from 4 secondary schools, educators and community members in a rural district in Kwa-Zulu Natal.
A total of 1164 in- and out-of-school youth attended the SRH&R education program. A headcount of 1355 accessed formal services at the various stations. A total of

395 children <5 years accessed services comprising of growth, nutrition support, immunization (43.7%), social-protection (30.6%) and documentation (14%). Adult headcounts (n=614) by serviced accessed included TB screening (14%), minor-ailments (32.7%), hypertension/diabetes (22%). 67.2% of 177 BMI screening were adults. Amongst youth (1164), 29.8% accessed SRH&R services (n=346), comprising of family planning (25.7%) HCT (22%), VMMC (n=42), pap-smears (n=5) and 6% were referred for nutritional support.
**Conclusions:** The findings suggest that health and welfare service uptake by leveraging-off existing platforms benefitted the youth and broader community members. These initiatives strengthen inter-sectorial linkages, community partnerships and more importantly educate and enable service uptake by communities experiencing multiple deprivation communities.

## TUPEE497

### ROLE OF CIVIL SOCIETY IN IMPLEMENTING CLIENT-CENTERED INTEGRATED SRHR AND HIV SERVICES IN BOTSWANA, MALAWI AND SWAZILAND 2011-2015

J. Hopkins[1], L. Mashimbye[2], A. Andersson[3], B. Dlamini[4], T. Mijoya[5], K. Koogotsitse[6]
*[1]IPPF, London, United Kingdom, [2]UNAIDS Regional Support Team, Eastern and Southern Africa, Johannesburg, South Africa, [3]UNFPA East and Southern Africa Regional Office, Johannesburg, South Africa, [4]UNFPA Swaziland, Mbabane, Swaziland, [5]UNFPA Malawi, Lilongwe, Malawi, [6]UNFPA Botswana, Gaborone, Botswana*
*Presenting author email: bodlamini@unfpa.org*

**Background:** The critical role of civil society in implementing health programmes is widely recognized, including in the provision of integrated SRH and HIV services. In Southern Africa, 7 countries piloted integration of SRHR and HIV between 2011 and 2015. This study presents the results of an assessment of civil society participation in 3 of the 7 countries implementing the programme, in particular the role of civil society organization (CSOs) in SRHR/HIV integration.
**Methods:** A qualitative study was conducted between March and September 2015 and included fieldwork in Botswana, Malawi, and Swaziland. Data was collected through desk-research and face-to-face semi-structured interviews with 24 key informants representing civil society, Government, and UN agencies. Five focus group discussions were conducted with 20 participants representing civil society. Data was recorded in the form of notes and tape recorders, and later transcribed. Transcripts were imported into Atlas ti. for data coding and analysis. Data was analyzed following a thematic analysis approach.
**Results:** CSOs had a critical value-added role in the implementation of SRH and HIV integration, particularly in the following areas:
*1. Advocacy:* CSOs had an important role in advocating for formulation and adoption of policies on integration of SRH and HIV. Equally, they also had an important role in holding governments to account and advocating for the implementation of these policies.
*2. Demand generation for integrated services:* Community outreach events, distribution of pamphlets, and direct interactions communities and community based organisations, was critical for reaching the marginalized and underserved, including young people.
*Service provision:* CSOs were vital partners to supporting the Government in demonstrating efficient and effective models of integrated service delivery that successfully provides a broad range of SRH and HIV services.
**Conclusions:** Civil society has a critical role in implementation and scaling up of SRH and HIV integration through advocacy, demand generation, and direct service provision. In an era of dwindling resources, it is vital to make the most of these synergies by strengthening partnerships between the Ministry of Health and civil society.

## TUPEE498

### MAKING 90-90-90 A REALITY: BUSINESS UNUSUAL IN SOUTH AFRICA

Y. Pillay[1], B. Muzah[2], S. Sehgal[3], R. Overmeyer[4], Z. Pinini[1], D. Mametja[1], P. Barron[1], L. Diseko[1], A. Ratshefola[1], E. Kiwango[3], Z. Mogale[1], C. Brokenshire-Scott[5], E. Morah[3], A. Reid[6]
*[1]National Department of Health, Pretoria, South Africa, [2]ICAP, Pretoria, South Africa, [3]UNAIDS, Pretoria, South Africa, [4]Foundation for Professional Development, Pretoria, South Africa, [5]USAID, Pretoria, South Africa, [6]UNAIDS, Geneva, Switzerland*
*Presenting author email: batanai.muzah@gmail.com*

**Background:** South Africa was one of the first countries to adopt ambitious 90-90-90 targets for HIV and TB by 2020. To fast track action, an innovative, bottom-up District Implementation Planning (DIP) process was introduced using a participatory approach to identify root causes of poor performance against 33 tracer indicators. The outcome is costed HIV and TB plans, per district, which consolidate all available resources and guide all stakeholders to ensure that funds flow to priority interventions, locations and populations. The process has unified action and strengthened collaboration between government, donors and implementing partners.
**Description:** 90-90-90 targets were developed and disaggregated across the provinces and districts down to facility level. Each province selected its twelve worst performing indicators across HIV, TB and PMTCT. Tools based on results based management were developed to promote analysis and use of data, facilitate concrete action planning, cost and budget the plans, and monitor progress towards the targets. Cascade analyses, indicator dashboards and bottleneck analysis tools were utilized during participatory workshops aiming to empower health workers and facility managers and ensure their experience informed planning of interventions to yield highest impact. Facility plans were consolidated up to district level and submitted for review by Provincial and National Departments of Health.
**Lessons learned:** Including all partners and stakeholders in a participatory process is complex but worthwhile. All 52 districts have submitted DIPs and these are guiding the funding allocation to be based on needs rather than historical performance. Health care workers and facility managers are mobilized and informed of their targets which strengthens motivation and accountability. All partners are informed of the DIPs and efforts are underway to align targets, planning and budgeting cycles at all levels.
**Conclusions/Next steps:** The DIP process is a concrete example of how ambitious global level targets can help countries to implement "business unusual". It has revolutionized planning, brought all partners together, and is merging top down and bottom up approaches. While it was initiated by NDOH and is currently health driven, the objective is to expand the core indicators to include structural drivers and promote data driven action for the multi-sectoral response going forward.

## TUPEE499

### THE 'TRINITY ALLIANCE' APPROACH IN PROMOTING ACCESS TO MEDICINES IN MAURITIUS, BOTSWANA AND ZIMBABWE

K.L. Mabote
*AIDS and Rights Alliance for Southern Africa, Advocacy, Cape Town, South Africa*

**Background:** Due to the lack of enabling Intellectual Property (IP) laws and policies, many SADC countries continue to experience consistent stock outs and are experiencing rising costs of second and third line HIV, TB as well as Hepatitis C medicines. This challenge presents itself in the face of dwindling donor support to some countries due to their graduation to middle-income status. The revised SADC Pharmaceutical Business Plan (SADC PBP) provides an opportunity for civil society to form better alliances with their governments as well as IP experts, in an effort to drive policy implementation that could yield sustainable availability and access to affordable, quality, safe, efficacious essential medicines.
**Description:** From November 2014 to December 2015, the AIDS and Rights Alliance for Southern Africa worked with partners in Botswana, Mauritius and Zimbabwe on Phase 1 of this Programme. Through mixed interventions, including preparation of Policy briefs from contextual situational assessments conducted, gaps were highlighted and 'low hanging fruit' for advocacy identified. Gaps included lack of coordination between ministries of Health, Trade and Finance in terms of where the Intellectual property and access to medicines agenda lies, coupled with outdated IP legislations and lack of knowledge about the opportunities the TRIPs flexibilities presented. At a regional level, the revised SADC PBP is being used as leverage.
**Lessons learned:** So far, alliances between civil society, their relevant government stakeholders (as mandate holders), as well as IP experts have been stabilised. Through the formation of the 'trinity alliance' civil society now have expanded reach into the inner workings of their ministries - in order to push for coordinated action. National plans have been developed to promote 'quick-and-dirty' advocacy to expedite IP legislative reform, and litigation strategies are in place to expedite action.
**Conclusions/Next steps:** By leveraging on the use of beneficial provisions in the TRIPS Agreement; and with a applied strategies towards strengthening of 'trinity alliances' between civil society, government and experts, work is underway to reform IP laws and formulate national IP policy frameworks.

## EFFECTS OF PUBLIC-PRIVATE PARTNERSHIPS, INCLUDING WORKPLACE PROGRAMMES AND POLICIES

## TUPEE500

### WEAVING HIV, FAMILY PLANNING AND SEXUAL AND REPRODUCTIVE HEALTH (SRH) SERVICES FOR FEMALE FACTORY WORKERS IN CAMBODIA THROUGH PRIVATE PARTNERSHIPS

N.K. Serbgeth Singh[1,2], V. Chivorn[2]
*[1]International Planned Parenthood Federation East & South East Asia and Oceania Regional Office, Integrated SRHR Programmes, Kuala Lumpur, Malaysia, [2]Reproductive Health Association of Cambodia, Phnom Penh, Cambodia*

**Background:** Garment manufacturing is the single largest industry in Cambodia which employs the most female workers. Mostly rural-urban migrants, these women are invisible and lack access to health information, quality SRH services, and supportive policy.
The Reproductive Health Association of Cambodia (RHAC) through Japan Trust Fund for HIV and Reproductive Health (JTF) provided HIV and SRH information and free services to women working in garment factories in three major cities.
**Description:** RHAC established partnerships with 30 factories. RHAC staff delivered interactive and fun lunchtime SRH and HIV information sessions.
RHAC trained factory clinic staff on providing health education including contraception and STI testing, and on client rights and basic clinical skills.
A voucher system was introduced and the women obtained a range of free SRH services including contraception, post-abortion care, HIV tests and cervical cancer screening at the closest RHAC clinic.
RHAC also adapted its clinic hours to open on Sundays during the workers' time off.
During the 2 year project lifetime, 18,283 VCT services and 51,829 STI treatment services were provided to female factory workers.
The provision of services increased exponentially, as shown by the indicators (quantitative) in the Table.

| Indicators | Baseline (2012) | Target (100% increase) | Actual: May 2013 - April 2015 |
|---|---|---|---|
| No. of clinic visits by female factory workers | 70,540 | 147,252 | 126,316 (86%) |
| No. of factory workers received STI services at RHAC clinics | 29,476 | 57,400 | 53,559 (93%) |
| No. of factory workers received family planning services at RHAC clinics | 3,612 | 6,700 | 7,426 (111%) |
| No. of female factory workers received post abortion care services at RHAC clinics | 979 | 1,900 | 2,780 (146%) |
| No. of factory workers received HIV counselling and testing (VCCT) | 10,394 | 25,582 | 21,582 (84%) |
| No. of factory clinic staff trained and provide quality RH services (in the second year) | 0 | 60 | 43 (73%) |
| No. of clinics in factory provide SRH services for workers | 0 | 30 | 30 (100%) |

*[Project Achievements, May 2013 - April 2015]*

**Lessons learned:** RHAC was able to generate more discussions among the factories, Garment Manufacturers Association of Cambodia, Ministry of Labour & Vocational Training and the Ministry of Health on the need to have a clear standard service package provided by the factory clinics.
This project is proof that women are able to attain the highest standard of health if we address SRH issues holistically.
**Conclusions/Next steps:** Through private partnership, RHAC reduced access barriers to HIV/SRH services, improved link to access to quality HIV/SRH services, and enhanced human resource capacity of factory health staff, contributing to the growth of manufacturing industries, as well as social development.
We aim to develop private partnership financing models that will sustain SRH information and service provision for the long term.

## TUPEE501

### BRAZILIAN STRATEGY FOR UNIVERSAL AND EQUAL ACCESS TO THE HIV-1 GENOTYPING IN THE UNIFIED HEALTH SYSTEM

A.F. Nacif Pinto Coelho Pires[1,2], R.B.L. Francisco[1], C.J.B. Batista[1,3], M.L. Bazzo[4], M. Franchini[1]
*[1]Ministério da Saúde, Departamento de DST/AIDS e Hepatites Virais, Brasilia, Brazil, [2]Universidade Federal de Brasília, Faculdade de Ciêncais da Saúde - Departamento de Saúde Coletiva Programa de Pós-Graduação em Saúde Coletiva, Brasilia, Brazil, [3]Universidade Federal de Santa Catarina, Programa de Pós-Graduação em Farmácia, Brasilia, Brazil, [4]Universidade Federal de Santa Catarina, Departamento de Análises Clínicas, Brasilia, Brazil*
*Presenting author email: aflaviapires@gmail.com*

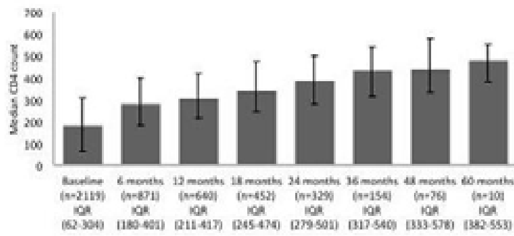
**Background:** In 2002, the Brazilian Ministry of Health (BMoH) implemented the National HIV-1 Genotyping Network (Renageno), in order to carry out genotyping of those living with HIV/AIDS in antiretroviral therapy that presented resistance to the drugs, and a Genotyping Network Information System (Sisgeno) with online access, that stores the genotyping results and enables monitoring from the day of the sample collection on.
Between the years of 2002-2015, there were 86,920 Trugene® tests distributed to 23 public laboratories for an average price of US$210 per unit, until the Trugene® kit was discontinued by its manufacturer.
**Description:** Due to the lack of another kit for Renageno Genotyping with commercial authorization in the country, the BMoH acquired, in December 2015, a genotyping exam conducted in-house, in a private laboratory, with a cost of US$127 per unit. This laboratory was hired to collect samples in 709 health services within 3 business days, carry out the Genotyping and release the results on Sisgeno within 12 business days, regardless of which municipality the sample came from. A Sisgeno analysis of in January 2016, one month after the implementation of the contract, demonstrated a reduction from 35 days in 2015 to 11.5 days in 2016 in the release of the Genotyping.
**Lessons learned:** This promising strategy minimizes regional disparities, some health services took 40 days to submit the samples for genotyping in Renageno, it allows agility in the analysis of possible resistance encountered and in the proposal for a new antiretroviral regimen, as well as therapeutic success for those living with HIV/AIDS. Another advantage is the 40% savings on the cost of Genotyping at a private laboratory in relation to the Trugene®.
**Conclusions/Next steps:** Brazilian health care policy granting free access to diagnosis, treatment and monitoring for those living with HIV/AIDS through viral load and CD4, with the possibility of using the agility of the private sector and government funding, ensuring the expansion, reduction in cost and shortest delivery time of genotyping, are important advances to reach a greater number of HIV infected people with undetectable viral load and decrease the number of new infections.

## TUPEE502

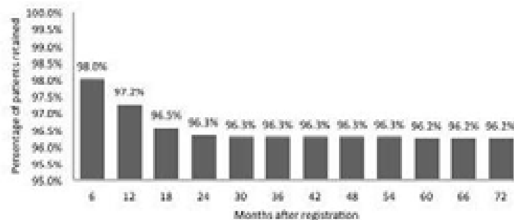
### IMMUNOLOGICAL AND RETENTION OUTCOMES FROM A COMMUNITY-SUPPORTED PUBLIC-PRIVATE HIV TREATMENT PROGRAM IN IN YANGON, MYANMAR

G. Mburu[1], A.Z. Paing[2], N.N. Myint[2], K.H. Thu[2], B. Wang[1], S. Naing[2]
*[1]International HIV/AIDS Alliance, Hove, United Kingdom, [2]International HIV/AIDS Alliance, Yangon, Myanmar*
*Presenting author email: gmburu@aidsalliance.org*

**Background:** This abstract describes immunological and retention outcomes within a public-private partnership between private sector general practitioners and community-based local non-governmental organization, the International HIV/AIDS Alliance in Yangon, Myanmar.
**Methods:** Retrospective analysis was conducted of 2,119 unique patient records dating from March 2009 to April 2015. The primary outcomes assessed from the date of enrolment in care were linkage to care, immunological response, retention and loss to follow-up, all-cause mortality, and survival. Follow-up time was calculated from the date of enrolment to date of death, loss to follow-up, transfer out or, if still alive, in the program until April 2015. The Cox proportional hazards model was used to identify predictors retention endpoints in bivariate and multivariate analysis.
**Results:** The median number of patients for each of the 16 general practitioners was 42 (IQR: 25-227) and the median follow-up period was 13 months. The median age was 35 years (IQR 30-41), 56.6% were men, 62% and 11.8 % % were in WHO stages III and IV at registration respectively, median CD4 count at enrolment was 177 cells/mm$^3$, and 90.7% were on ART) in April 2015. During follow-up, patients' CD4 counts increased from a median of 177 cells/mm$^3$ to 274, 307, 387, 432, 439 and 482 cells/mm$^3$ at 6, 12, 24, 36, 48 and 60+ months respectively. Patient retention was 98.9% at six months, and remained over 97% for up to 72 months.



*[Figure 1. Trends in immunological recovery during follow up]*



*[Figure 2. Good retention levels were observed during the follow up]*

Overall, 3.3 % patients were lost to follow-up, 4.2 % were transferred out to other health facilities, and 8.3% died during the follow-up period. Retention was associated with older age (aOR 0.934; 95% CI: 0.89-0.97%, p=< 0.001), being on ART (aOR 0.0101; 95% CI: 0.003-0.014%, p=< 0.001).

**Conclusions:** Effectively supported private sector general practitioners successfully retained patients on antiretroviral therapy in Myanmar, suggesting that community-supported public-private partnerships can contribute to expansion of HIV treatment.

## WORKING WITH COMMUNITY-LED ORGANIZATIONS, INCLUDING OF KEY POPULATIONS, FAITH-BASED GROUPS, AND TRADITIONAL HEALER ORGANIZATIONS, AND WITH COMMUNITY LEADERS

### TUPEE503

#### HIV-RELATED KNOWLEDGE AND PRACTICES AMONG TRADITIONAL HEALERS IN MAPUTO, MOZAMBIQUE: IMPLICATIONS FOR SCALING UP HIV CARE AMONG COMMUNITIES RELIANT ON "TRADITIONAL" MEDICINE

R. Sundararajan[1], P. Langa[2], S. Manuel[3], T. Morshed[1], R. Schooley[4]
*[1]University of California, Emergency Medicine, San Diego, United States, [2]Universidade Eduardo Mondlane, Sociology, Maputo, Mozambique, [3]Universidade Eduardo Mondlane, Anthropology, Maputo, Mozambique, [4]University of California, Infectious Diseases, San Diego, United States*
*Presenting author email: rsundararajan@ucsd.edu*

**Background:** "Traditional" or spiritual healers provide the majority of healthcare in some of the most highly HIV-endemic regions. Despite their central roles in affected communities, their HIV-related knowledge, practices and relationships with biomedical providers are largely unknown. This dearth of knowledge limits efforts to mitigate the HIV epidemic in these resource-limited contexts.

**Methods:** We employed ethnographic methods of minimally-structured interviews and participant-observation to gain information regarding "Traditional healer" treatment practices, HIV-related knowledge and attitudes towards biomedical resources. Between February and May 2016, 40 healers from Maputo City participated in the study. Interviews and observations were analyzed using content analytic methods to identify significant themes. The KQ-18 scale was also administered to all participants to quantitatively measure HIV-related knowledge. Socio-demographic information collected from all participants included age, gender, practice volume, geographic location and highest level of formal education.

**Results:** HIV-related knowledge varied by geographical location of healers (urban versus rural district), as well as healers' age. Practices of cutting, burning or blood-letting, associated with risk of spreading HIV were uncommon among our participants. The theme of *marginalization* was common among traditional healers as it related to their position as healthcare providers for their clients. Relationships between healers and biomedical providers involve mutual distrust, though healers are open minded about the possibility of working with allopathic providers in the future in order to improve access to HIV care for their clients.

**Conclusions:** Mozambican traditional healers play a central role in community health, yet some scored poorly on the HIV-related knowledge scale. Relationships with biomedical facilities are mutually distrustful, which impedes the processes of referral for HIV testing and/or ART medication treatment for those who are HIV-infected. Efforts to scale up HIV care and testing should involve traditional healers in order to have the greatest reach in this highly endemic area. Our data suggest that healers are open and willing to collaborate with biomedical providers in these efforts.

### TUPEE504

#### A CHILD HEALTH AND PROTECTION SYSTEM BORN OUT OF AN HIV/AIDS PILOT IN CHINA

W. Xu[1], J. Xu[2], Y. Qiao[3], S. Xu[4]
*[1]UNICEF, Beijing, China, [2]Chinese Ministry of Civil Affairs, Beijing, China, [3]Natioanal Center for Women and Children's Health, Beijing, China, [4]Beijing Normal University, Beijing, China*
*Presenting author email: wxu@unicef.org*

**Background:** An equity-based pilot for inclusive social support and protection services is implemented in eight rural counties hard-hit by HIV/AIDS of southwest China. It aims to promote timely access and utilization of HIV testing and counselling, treatment adherence for Prevention of Mother-to-Child Transmission (PMTCT) and treatment of HIV-positive new-born. These counties are inhabited by ethnic minority groups, migrant workers and are mostly poor. The Ministry of Civil Affairs, the National Health and Family Planning Commission and UNICEF have designed a child welfare model to enhance equitable access under the overarching rights-based framework.

**Description:** The pilot supports link-up of the most vulnerable children and women to social support and protection services, including timely HIV/AIDS diagnosis, counselling and treatment. A community level barefoot social worker network is established, one worker for each community to provide a range of services, foremost, birth and civil registration. Without an identity and the necessary papers, these families cannot access medical subsidies and social services. The barefoot social workers identify vulnerable children in their community, conduct household visits, monitor that subsidies are spent as intended, and provide referral to PMTCT and treatment. They also work with HIV-positive support groups in peer support.

**Lessons learned:** Between 2011 and 2015, over 90% of children without Hukou or civil and birth registration in the eight project counties were given IDs and received needed social services. Over 75% of infants exposed to HIV/AIDS had received early infant diagnosis (EID) in 2015 compared to zero in 2011. Data from a project county showed over 90% of pregnant women tested for HIV, and 65% of them treated at the early stage of pregnancy in 2015, a significant increase from 20% in 2011. Key policies were developed to facilitate Hukou registration, cash transfer, and timely follow up for the most vulnerable women and children.

**Conclusions/Next steps:** Between 2011 and 2015, timely diagnosis and treatment rate of pregnant women tripled following introduction of the newly developed PMTCT and EID implementation policies. The number of children without access to social support and protection services also dropped significantly as a result of these interventions and the newly developed social protection policies.

### TUPEE505

#### INVOLVING COMMUNITY LEADERS AND CBOS FROM DESIGN PHASE LEADS TO STRONG RESULTS IN ADDRESSING GBV AND HIV PREVENTION

H.S. Bryant[1], K. Van Cranenburgh[2,3], C. Arregui[2], M.R. Miguel Vilanculos[4]
*[1]FHI 360, Social and Economic Development, Maputo, Mozambique, [2]Community Wisdom Partners, Barcelona, Spain, [3]University of Barcelona, Barcelona, Spain, [4]FHI 360, Program, Maputo, Mozambique*

**Background:** : In Mozambique, HIV prevalence is 13.1% for women, 9.2% for men, 1 in 3 women experience physical violence; 12% of women over 15 experience sexual violence. Risk factors include early marriage, transactional sex, and male dominance in decision making. Under the PEPFAR Gender-based Violence Initiative, USAID/Mozambique supported the Capable Partners Program (CAP) to scale up GBV prevention within their capacity building program. When six community-based organizations (including one faith-based organization) (CBOs) identified the influence that gender and GBV had on HIV vulnerability in their communities, CAP provided training and technical assistance to help these CBOs engage community leaders, design and implement social and behavioural change communication activities that address gender norms/GBV and HIV together.

**Description:** In collaboration with community leaders, CBOs organized series of 8-12 small group debates addressing gender-based risk factors and barriers to HIV prevention and testing. CAP provided support in ensuring quality implementation and produced videos on gender and HIV to spur reflective discussion of these sensitive topics. Interventions aimed at preventing sexual transmission of HIV and pro-

moting HIV testing reached 70,892 women and men ages 15-49 in four provinces during 2012-2015. A 2014 quantitative cross-sectional endline population survey interviewed 1531 men and women aged 15-49 about HIV prevention knowledge, attitudes and behaviors, comparing people exposed to CAP to those not exposed. This survey found a positive association between participation in interventions, and more balanced community gender norms and increased preventive behaviors

**Lessons learned:** A team of consultants interviewed CBO representatives and outreach workers to document the process and identify key factors that lead to this success. This qualitative case study identified the following success factors:

1. communities identified gender norms as a factor in HIV transmission;
2. sound, relevant methodologies,
3. comprehensive capacity building,
4. resources invested for long-term results,
5. ownership of interventions by CBOs and community leaders.

**Conclusions/Next steps:** When communities and leaders are engaged in identifying the issues and supported to shape interventions that are meaningful, change in seemingly intransigent norms can happen.

## TUPEE506

### A STRATEGIC RESPONSE TO TB AT THE WORKPLACE: CALL FOR A PUBLIC-PRIVATE-CIVIL SOCIETY MIX

L. Roets[1], S. Preller[2], R. Makombe[3], J. Zingwari[3], R. Matji[3], S. Nyathi[3], M. Boakye[1], R. Patrone[1], G. Bhuda[1], L. Lebona[3]

*[1]University of South Africa, Pretoria, South Africa, [2]South African Business Coalition for Health and AIDS, Johannesburg, South Africa, [3]University Research Co, LLC, Pretoria, South Africa*

*Presenting author email: leratole@urc-sa.com*

**Background:** Tuberculosis (TB) is affecting the most economic productive part of the South African population and it has serious socio-economic implications to the business sector. Some of these implications are related to lower productivity through series of absenteeism and presenteeism, direct and indirect costs, succession planning, and overall wellness in the workplace. Workplaces are also directly linked to communities and households which should form part of a comprehensive, integrated health and wellness workplace program.

**Methods:** The South African Business Coalition for Health and AIDS (SABCOHA) in collaboration with the TB CARE II Project funded by the United States Agency for International Development (USAID) and implemented by University Research Co., LLC (URC) and the University of South Africa (UNISA) hosted a series of twelve provincial and national round table discussions to develop a national strategic response framework to TB management at the workplace. Different role-players and stakeholders, including community-based organizations, government departments, workplace health care practitioners, managers and peer educators, and trade unions were amongst the participants of these sessions. Participants were asked to answer five strategic questions providing the needed evidence for the framework development. Key findings were analyzed using theme-analysis to code.

**Results:** The participants identified 5 common priorities for the development of TB in the workplace strategic framework. These include intensifying TB knowledge, awareness and education interventions, collaboration between workplaces and communities, deal with TB treatment defaulters and resistance in a more comprehensive and preventative way, develop and strengthen multi-stakeholder strategies to address the link between HIV and TB in the workplace, communities and households; and strengthen monitoring and evaluation activities. Key lessons learned included the importance of workplace peer educators as key drivers of prevention, case detection, treatment adherence and importance of mobilizing workplace leadership response at all management levels to address TB within a social ecology understanding.

**Conclusions:** Workplaces must integrate TB management within a comprehensive employee health and wellness program3. Optimal care and prevention can only be achieved through a multi stakeholder approach and strong public-private-civil society partnerships are needed to curb the TB epidemic and to reduce stigma related to HIV and TB within workplaces, communities and society.

# SEXUAL AND REPRODUCTIVE HEALTH AND HIV SERVICES: DELIVERY MODELS AND COSTS

## TUPEE507

### INTEGRATING SEXUAL AND REPRODUCTIVE HEALTH (SRH) SERVICES IN COMMUNITY HCT OUTREACHES CRITICAL FOR HCT UPTAKE BY YOUNG PEOPLE: LESSONS FROM NAGURU TEENAGE INFORMATION AND HEALTH CENTRE (NTIHC), KAMPALA, UGANDA

W. Musubika[1], S. Kadokech[2], H. Ntale[3]

*[1]Naguru Teenage Information and Health Centre, Service Delivery Department, Kampala, Uganda, [2]Naguru Teenage Information and Health Centre, Monitoring and Evaluation, Kampala, Uganda, [3]Naguru Teenage Information and Health Centre, Advocacy, Kampala, Uganda*

*Presenting author email: winibika@yahoo.com*

**Background:** Recent reports indicate that adolescents and young people remain extremely vulnerable to acquiring HIV infection with over 35% of new infections being among young people 15- 24 years. HIV counseling and testing (HCT) has been advanced as a key prevention strategy for early diagnosis to reduce the risks of transmission and promote early treatment. However, HCT services are underutilized among young people consequently leading to increase in the number of new infections in this age group. The aim of this paper is to share the importance of integrating SRH services into HCT services on HCT uptake among young people (10- 24 years).

**Description:** In July 2014, NTIHC started integrating SRH services including Family planning and STI management into HCT outreaches in the community. Prior to this, only HCT services were provided during the outreaches. Data was collected for the period and the numbers of young people reached with HCT services during outreaches in the period before integration (July 2013- June 2014) was compared with data for the period after integration (July 2014 to June 2015).

**Lessons learned:** There was a significant increase to attendance for services during outreaches from 30 young people per outreach to an average of 80 per outreach. The number of young people who received HCT services doubled from 3200 (266 monthly attendance) before integration to 6218 (518 monthly attendance) after integration. Over 50% of the young people who came for other SRH services ended up taking an HIV test.

**Conclusions/Next steps:** Integrating HCT with other SRH services during outreaches can lead to increase in numbers of young people who take up HCT services. Young people who come for Family Planning or STI treatment present an opportunity for the service provider to discuss HCT hence increasing utilization of HCT services.

## TUPEE508

### ASSESSING KNOWLEDGE AND PREFERENCES OF SEXUAL AND REPRODUCTIVE HEALTH SERVICES AMONGST YOUNG PEOPLE AND ADOLESCENTS IN HIV CARE IN RURAL AND URBAN CAMEROON

E. Tata Joan

*United Vision Cameroon, HIV/AIDS,SRHR, Mamfe, Cameroon*

*Presenting author email: enohtata@yahoo.com*

**Background:** Young people and adolescents still remain at risk of contracting HIV and other STIs. In Cameroon, the prevalence of HIV/AIDS amongst young people is 1.4% which constitutes about 46% of all new infection amidst the efforts of international, national and local AIDS control programs. Though a lot of focus is laid on abstinence and delaying sexual initiation, adolescents are still engaging in risky sexual behaviors. Youth need accurate, culturally relevant, age-appropriate, youth friendly, non-judgmental information about HIV transmission and infection, as well as, information on how to protect themselves, their partners, including abstinence, contraception, safer sex practices and where to get tested. HIV education and SRHR services must complement each other and be made readily available to all youth, regardless of level of education or sexual activity. This study aimed to assess knowledge of and preferences for SRHR services among adolescents and young people accessing HIV care services in rural and urban Cameroon.

**Methods:** The study involved one rural and one urban community. A self reporting structured questionnaire which sought to assess knowledge of existing SRHR services within the health facility, and preferences for SRHR services were administered to 100 young people and adolescents attending HIV treatment centers in both communities.

**Results:** 85% of our participants were young girls with an average age of 23years. The 15% of young boys had an average age of 27years. 87% of our participants did not have any knowledge of existing SRHR services within the health facility. Of the 13% who knew/used SRHR services, 80% of them were in the urban setting and preferred seeking such services from other health facilities due to the fear of being

judged. All of our participants admitted to needing youth friendly SRHR services and 92% of them did not know exactly where to find them.
**Conclusions:** This survey provides strong evidence of how low knowledge of SRHR services are to young people in HIV care in urban and rural Cameroon. This study reinforces the role of the health facility in incorporating age-appropriate SRHR services when delivering HIV prevention, treatment and care to young people and adolescents.

## TUPEE509

### CHALLENGES AND OPPORTUNITIES FOR SCALING UP AN INTEGRATED SEXUAL REPRODUCTIVE HEALTH SERVICES IN REFUGEE SETTLEMENT OF MBARARA PROVINCE, UGANDA

M. Migombano[1], R. Lokhande[2], D. Bakomeza[3]
*[1]International Planned Parenthood Federation, Africa Regional Office, Programme and Technical Support, Nairobi, Kenya, [2]International Planned Parenthood Federation - South Asia Regional Office, The SPRINT Initiative, Dehli, India, [3]Reproductive Health Uganda, Programme, Kampala, Uganda*
*Presenting author email: mmigombano@ippfaro.org*

**Background:** In 2015, following the influx of Burundian refugees in Nakivale, Uganda, Reproductive Health Uganda (RHU), implemented the Minimum Initial Services Package (MISP) in humanitarian crisis for three months (August - October 2015). The project benefitted over 45,500 refugees through 20 service delivery points in four areas of Nakivale province, providing sexual, reproductive health services including family planning, HIV counselling and testing, and sexually transmitted infections management along with community sexual and reproductive health awareness sessions.
**Description:** The programmatic review of this study was conducted through primary and secondary data collected through SPRINT project reports, observations, field visits, case studies and semi-structured interviews with the beneficiaries, project staff and other stakeholders. To assess the quality of care component, tools such as client exit interviews and RH camp assessment tool were applied wherein fourteen client exit interviews and two Reproductive Health camps were assessed.
**Lessons learned:**
- The work-load was quite high, based on the observation approximately 250-300 clients were provided Maternal and Child Health services per day
- Low community awareness and knowledge about HIV and its impact on health increased their exposure to HIV due to their high risk behavior and sexual networks
- With close collaboration with the Government and UN agencies, this project has the scope of integrating their existing activities including capacity building of village health team on MISP
- Though all family planning services were available, these were under-utilized due to cultural barriers
- Multi-linguistic translator not from the local community and sensitive to the refugees' needs
- Specific counseling skills for GBV and HIV positive cases
- Involvement of adolescent and youths as volunteers
- Transfer of skills to the existing medical team on cervical cancer screening and management.

**Conclusions/Next steps:**
- In protracted crisis, with well-established health service delivery structure, provision of services like cervical cancer screening, which are beyond MISP activities, helps in community mobilization and health seeking behavior
- Crisis involving refugees from different countries needs special attention in terms of culturally sensitive apart from multi-linguistic service providers
- Well coordinated and collaborated activities among the partners help in effective utilization of resources and transfer of skills.

## TUPEE510

### FACTORS INFLUENCING THE IMPLEMENTATION OF PROVIDER-INITIATED TESTING AND COUNSELING (PITC) AMONG STI CLIENTS IN SOUTHERN MALAWI: A MIXED METHODS STUDY

K. Dovel
*University of Colorado Denver, Health and Behavioral Sciences, Denver, United States*
*Presenting author email: kathryn.dovel@ucdenver.edu*

**Background:** Provider-initiated-testing-and-counseling (PITC) is critical to identify new HIV infections among high-risk populations. While routine PITC is recommended in generalized epidemics, the implementation of PITC outside antenatal services is limited. This paper uses data from a mixed-methods study to identify factors that influence the implementation of PITC among STI clients in southern Malawi.
**Methods:** Five health facilities ranging in size, location, and models for STI service delivery were purposely selected. Exit surveys were conducted with 299 clients seeking STI services. In addition, 18 in-depth interviews with service providers and participant observation over a 5-month period were conducted to further examine barriers to policy implementation.
**Results:** Two models of care were identified:
(i) specialized services (providers only offered STI services in designated STI rooms) and
(ii) integrated services (services offered alongside other outpatient services in non-specific consultation rooms).
61% of clients requiring PITC were not informed about HIV testing, with significant differences between specialized (38.83%) and integrated (79.17%) models of care. Neither model provided HIV testing during STI consultations. Clients told about testing were expected to independently seek out HIV services after completing STI consultations. As a result, being told about testing rarely translated into same-day testing.
Younger and older clients were less likely to be told about testing (AOR 1.45, 95%CI 1.04-2.00; AOR 0.99, 95%CI 0.99-0.99). When controlling for individual characteristics, specialized models of care (AOR 6.31, 95%CI 2.99-13.29) and comprehensive STI services (AOR 1.96, 95%CI 1.31-2.93) were associated with providers' discussing HIV testing with clients.
Several factors were identified as to why providers in specialized models were more likely to discuss testing than those in integrated models: providers received comprehensive training on STI services; had greater knowledge of STI service protocols; felt less overwhelmed by client loads; and felt more responsible to complete STI registers.
**Conclusions:** The organization of PITC had significant implications for policy implementation. Importantly, both integrated and specialized models did not provide testing during STI consultations, largely negating the potential impact of PITC. To achieve the maximum benefits of PITC, HIV testing should be fully integrated into routine consultations. Providers also need regular trainings on PITC protocols.

## TUPEE511

### HIV-POSITIVE WOMEN'S SEXUAL AND REPRODUCTIVE HEALTH NEEDS AND HEALTH SEEKING BEHAVIORS IN JOHANNESBURG, SOUTH AFRICA

N. Lince-Deroche[1], C. Hendrickson[1], T. Sineke[1], M. Mulongo[2], C. Firnhaber[2,3]
*[1]Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [2]Right to Care, Johannesburg, South Africa, [3]Clinical HIV Research Unit, Johannesburg, South Africa*
*Presenting author email: nlince-deroche@heroza.org*

**Background:** South Africa has committed to achieving universal access to sexual and reproductive health (SRH). Given the country's HIV prevalence, special consideration is required regarding how to address HIV-positive women's SRH needs.
**Methods:** We aimed to assess HIV-positive women's SRH needs and care access patterns. From June-November 2015 trained interviewers approached HIV-positive women presenting for treatment at a large, public HIV-treatment facility in Johannesburg, South Africa. Women, approached using a systematic random sample, were eligible for a semi-structured interview if aged 18-49. We analyzed closed-ended interview responses descriptively in Stata (v14.0). Open-ended responses were analyzed using thematic analysis.
**Results:** We approached 369 women, and 192 (52%) were eligible/enrolled. Median age was 39.6 (IQR 35.0-43.6). The majority were Black African (94.8%) and married/cohabitating (40.6%). 39.1% made 6-10 visits to health facilities per year for their HIV and other health conditions; 25.0% reported more than 10 visits per year. The majority (n=160, 83.3%) currently used modern contraception. Two-thirds (n=117, 61.3%) wanted no (more) children, but of those, 23 (19.7%) were not using a method. Table 1 illustrates other SRH needs and health seeking behaviors in the last year.

| | Pap smear | Breast exam | Menstrual problems | STI symptoms | Fertility problems | Menopause symptoms | Gender-based violence |
|---|---|---|---|---|---|---|---|
| | *n=192* | *n=192* | *n=192* | *n=165 sexually active women* | *n=13 who tried to fall pregnant* | *n=146 women >34 years old* | *n=192* |
| Had problems or symptoms | N/A | N/A | 70 (36.5%) | 26 (15.8%) | 9 (69.2%) | 38 (26.0%) | 24 (12.5%) |
| Of those with problems, sought help at a health facility | 168 (88.0%)* | 36 (18.8%)* | 34 (48.6%) | 18 (69.2%) | 7 (77.8%) | 14 (36.8%) | 6 (25.0%) |

Author Index

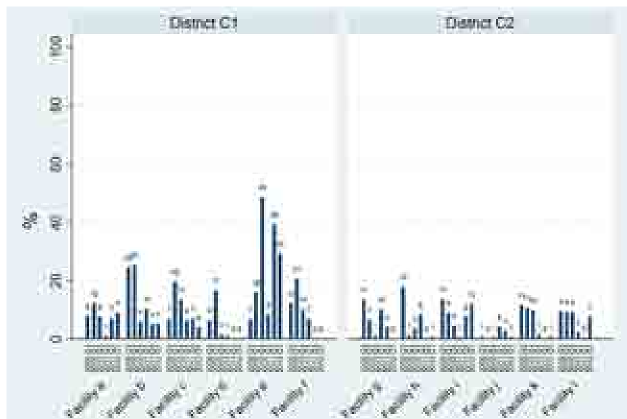
Fear of “bad” results prevented women from doing Paps and breast exams. Women also said they had not had a breast exam because they did exams at home and did not know where to go to obtain one. Lack of information on where to get help also frequently prevented women from obtaining care for menopause symptoms. Women with STI symptoms who didn’t seek care said they self-medicated or that the problem “went away.” Women with menstrual problems mentioned that the problems were transient, that they were “normal,” and that there was “no reason” to go to a doctor. 89.1% of women wanted information on SRH to be spontaneously offered at all visits to health facilities regardless of the reason.
**Conclusions:** Many HIV-positive women in care have unaddressed SRH needs. Health care providers should view each patient visit as an opportunity to provide education and support on SRH issues.

## TUPEE512

### INTEGRATION OF HIV AND REPRODUCTIVE HEALTH SERVICES IN PUBLIC SECTOR FACILITIES: ANALYSIS OF CLIENT FLOW DATA OVER TIME IN KENYA

I. Birdthistle[1], J. Fenty[1], S. Mayhew[2], M. Collumbien[2], C. Warren[3], J. Kimani[4], C. Ndwiga[4]
*[1]London School of Hygiene & Tropical Medicine, Population Health, London, United Kingdom, [2]London School of Hygiene & Tropical Medicine, Global Health & Development, London, United Kingdom, [3]Population Council, Washington DC, United States, [4]Population Council, Nairobi, Kenya*
*Presenting author email: isolde.birdthistle@lshtm.ac.uk*

**Background:** Integration of HIV/AIDS services with reproductive health (RH) care is expected to increase the uptake and efficiency of services, yet little is known about levels of integration in practice. We assessed the extent and nature of service integration in government facilities in Kenya, before and after an intervention designed to improve integration.
**Methods:** Between 2009-2012, client flow assessments were conducted at six time points in 24 facilities, purposively selected as intervention or comparison sites. A total of 25,539 visits were tracked: 15,270 in districts where 6 of 12 facilities received an intervention to strengthen HIV/STI service integration with family planning (HIV-FP); and 10,266 visits in districts where 6 of 12 facilities received an HIV-PNC intervention, 2009-2010.
Main outcome measures: The proportion of all visits in which an HIV/STI testing, counselling or treatment service was received with an RH service (family planning counseling or provision, antenatal care, or postnatal care); the proportion of visits in which individual HIV counselling was received.
**Results:** Levels of integrated HIV-RH services and HIV counseling were generally low across facilities and time points. An initial boost in integration in most intervention sites subsequently declined after the first follow-up.



*[Figure 1. Proportion of visits in which integrated HIV-RH services were received, by facility, round and intervention (HIV-FP model in District C1)]*

Integration was driven by temporary rises in HIV counseling. The most consistent combination of HIV/STI services was with antenatal care, except for the initial increase in intervention facilities, which was driven by integration with FP counseling and provision. HIV/STI services were least often received with PNC.
**Conclusions:** The initiative demonstrated a short-term boost in integration, with family planning services providing a good opportunity to expand integration. Without the direct support and supervision of the intervention, integration was not sustained. Declines across time and sites may reflect changes in staffing and redeployment due to district boundary changes, inconsistent commodity supply, and challenges in supervision and team communications necessary to deliver integrated care.

## TUPEE513

### INTEGRATING HIV AND SEXUAL AND REPRODUCTIVE HEALTH SERVICES IN CLINICS IN ZIMBABWE: EVOLVING VIEWS OF END-USERS AND PROVIDERS

M.K. Tumushime[1], E.L. Sibanda[1], K.E. Hatzold[2], F.M. Cowan[1,3]
*[1]Centre for Sexual Health and HIV/AIDS Research (CeSHHAR), Harare, Zimbabwe, [2]Population Services International Zimbabwe (PSI Zimbabwe), Harare, Zimbabwe, [3]University College London, Department of Infection and Population Health, London, United Kingdom*
*Presenting author email: mary@ceshhar.co.zw*

**Background:** Access to cervical cancer screening (CCS) and family planning (FP) services in Zimbabwe is sub-optimal and may be increased by integration with HIV programs. Population Services International Zimbabwe (PSI/Z) has integrated CCS and FP into existing HIV testing and treatment services. We used serial qualitative interviews to explore evolution of client and healthcare worker (HCW) views on service integration.
**Methods:** At three PSI/Z directly-managed clinics and one public-private partnership clinic, in-depth interviews were held with clients in November/2013-March/2014 (Phase 1), November/2014-March/2015 (Phase 2) and December/2015-January/2016 (Phase 3). HCWs were interviewed in-depth in phases 1-2 and had focus group discussions (FGDs) in phase 3. Data were analysed thematically.
**Results:** 32, 37 and 33 clients aged 18-52 years were interviewed in Phases 1, 2 and 3 respectively. 26 and 20 HCWs were interviewed in Phases 1&2; 34 undertook 4 FGDs in Phase 3.
Across phases, clients and HCWs viewed integration positively because
(i) it improved access to all provided services;
(ii) co-location of services saved travel time and money; and
(iii) it promoted awareness of services - client awareness of CCS improved from phase 1-3. Additionally, clients thought having a single waiting room for various services protected against stigma associated with accessing HIV-related services (Phase 3).
Most clients were satisfied with service quality; a few felt HCW were overwhelmed, leading to provision of selective information and long waiting times.
More HCWs were trained in CCS and LARCs over the 3 phases however some knowledge gaps remained. HCWs reported that integration allowed professional growth particularly for those with clinical backgrounds (all phases). Internal referrals, effective in promoting linkage to care, worked best between HIV and CCS services and less so for clients primarily seeking FP. HCWs’ challenges included
(i) sub-optimal coordination between departments;
(ii) difficulties tracking referred clients;
(iii) demand for services exceeding capacity (space and equipment);
(iv) difficulty achieving service targets; and
(v) inaccurate information-sharing amongst clients.
**Conclusions:** Integration has increased access to, uptake of and awareness of HIV and SRH services. Interventions aimed at capacity strengthening, team-building and dissemination of accurate information to clients are likely to further improve implementation and uptake of services.

## TUPEE514

### “4 SMART YOUTH” MOBILE APP REACHING VULNERABLE YOUNG PEOPLE IN MYANMAR WITH HIV/SRH INFORMATION

N.L. Tun[1], G. Gray[2], E.M. Kyaw[2], A.M. Tun[1], S. Naing[2], E.M. Soe[2]
*[1]International HIV/AIDS Alliance in Myanmar, Program, Yangon, Myanmar, [2]International HIV/AIDS Alliance in Myanmar, Yangon, Myanmar*
*Presenting author email: naylintun87@gmail.com*

**Background:** Link Up Myanmar aims to increase health seeking behavior and uptake of joined up and tailored HIV/SRH services among young people affected by HIV, especially those living with HIV, MSM, sex workers, people who use drugs and transgender young people (YKP), aged 10-24. Rapidly emerging mobile technology is being widely used by young people. Link Up is reaching hard to reach, hidden YKPs by using a mobile application (app) as a HIV/SRH education tool. “4 smart youth” education tool was released in July 2015, with high community acceptance and uptake.
**Methods:** Development of “4 smart youth” involved YKP throughout the planning and implementation. The project began with a YKP consultation to better understand their buy-in and information needs and design parameters. The final version includes live chat and forum where YKP can ask questions publically or privately about HIV/SRH. Trained Link Up counsellors respond and refer individuals onto services. Offline features include a catalogue of HIV/SRH information and a directory of HIV/SRH prevention and treatment services, which can be sorted by location and types of services. Links to HIV/SRH information website in Burmese and the official Link Up Facebook page are also provided.
**Results:** Putting YKP at the centre of developing this tool has ensured that it is addresses their HIV/SRH information needs and has established a strong youth-adult

partnership. The app brings HIV/SRH information and support directly into young people's hands and gives them options about how to access information. To date over 2000 YKP have used the app with over 33% as return users. This all-in-one education tool is very convenient and has the potential to reach more hard to reach youth than traditional IEC materials and health education.
**Conclusions:** 4 smart youth" has shown the potential of effective youth-adult partnerships for developing innovative technology. The process can be applied to developing other youth-friendly health and well-being programmes and technologies. The tool can also be used by peer educators and in the field. Additional work is needed to ensure that the app itself is easily updated and can respond to the challenges of slow internet speeds for online users.

## TUPEE515

### PATIENT PREFERENCES FOR SAFER CONCEPTION SERVICE DELIVERY: FINDINGS FROM A DISCRETE CHOICE ANALYSIS

S. Schwartz[1,2], N. Davies[2], S. Mullick[2], D. Blaauw[3]
*[1]Johns Hopkins University, Epidemiology, Baltimore, United States, [2]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [3]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa*
*Presenting author email: ndavies@wrhi.ac.za*

**Background:** There are increasing calls for expansion of safer conception services (SCS) for HIV-affected couples trying to conceive. However little evidence exists regarding what service attributes patients prefer most to inform SCS scale-up.
**Methods:** A discrete choice experiment (DCE) was conducted with patients attending various services at a large primary healthcare clinic in Johannesburg, South Africa. Eligible individuals were ≥18 years, planning to conceive within 12 months, and in a relationship in which either/both partners were HIV-positive or of an unknown status. The DCE design informed by qualitative work assessed how different service delivery attributes affected preferences for attending a safer conception clinic (Figure 1). Conditional logistic regression and partial log-likelihood comparisons were used to examine the importance of attributes on service delivery preference.

| Attributes | Levels |
|---|---|
| Type of healthcare worker | An HIV lay counsellor who is trained to provide HIV testing and counselling, ARV treatment support and safer conception counselling |
| | A Professional nurse |
| Operating days | Two week days per week, no Saturday clinic |
| | Two week days per week, including one week day and every Saturday |
| | Five days per week, no Saturday clinic |
| | Five days per week , including four week days and every Saturday |
| Type of counselling to deliver information about how to get pregnant safely | Each couple would not receive face-to-face counselling but would be given written information to take home and read together. You will have an opportunity to ask your healthcare provider questions at your next visit. |
| | A trained healthcare worker will provide group counselling for several couples at the same time (men and women in one room together) |
| | A trained counsellor will provide group counselling for women in one group and men in a separate group - men and women will not be counselled together. |
| | A trained healthcare worker will provide couple counselling in a private room with you and your partner being seen together |
| Total time spent at the clinic | 2 hours |
| | 4 hours |
| | 6 hours |
| | 8 hours |
| Consistency of healthcare provider | You may see a different healthcare provider at each visit |
| | You will see the same healthcare provider at every visit |

*[Figure 1: Attributes and levels choices for the service delivery discrete choice experiment]*

**Results:** Overall 505 participants (69% female) enrolled into the DCE between September 2015-January 2016. The median age was 33 years [IQR:28-37]. Participants were in seroconcordant (n=191, 38%), serodiscordant relationships (n=105, 21%), and unknown status relationships (n=209, 41%). Combined DCE results indicate the type of counselling sessions offered was the most important attribute driving SCS preferences. Participants displayed greatest preference for couples' counselling, followed by group single-sex counselling, then group co-ed counselling and lastly informational leaflets. Continuity of healthcare providers across visits was the second most important attribute, followed by type of healthcare worker (nurse preferred over counsellor), weekend operating hours, shorter time spent at clinic and lastly number of operating days per week. In sub-group analyses, women's most valued attribute was method of counselling, followed by type of healthcare worker, whereas men similarly valued the method of counselling, followed by weekend hours.

**Conclusions:** Considering client preferences for private couples' counselling, effective SCS implementation will rely on sufficient consultation time and physical space availability. Given challenges engaging men in care, weekend hours should also be considered to maximize SCS uptake.

## TUPEE516

### IMPACT OF COMMUNITY MODELS IN SRHR AND HIV FOR YOUNG PEOPLE

L.C. Mbewe[1,2]
*[1]Centre for Youth Empowerment and Civic Education, Youth, Lilongwe, Malawi, [2]NGO, Lilongwe, Malawi*
*Presenting author email: crown76.lucky@gmail.com*

**Background:** Centre for Youth Empowerment and Civic Education (CYECE) has been implementing an SRHR project called Unite Against Child marriages in Dedza district which focused on addressing harmful, cultural and religious beliefs which fuel child marriages among adolescent girls funded by the Dutch Government through an organization called CHOICE for Youth and Sexuality. The main object of the project was to reduce cases of child marriages by creating an enabling environment for girls SRHR using community based models.
**Description:** CYECE created and implemented a *Cultural Model* as follows;
1st Phase: Community Mobilization & capacity building: Traditional leaders were mobilized and trained on the SRHR issues for young people to make them champions of child marriages within their communities.
2nd Phase: Whole community awareness dangers of child marriages: CYECE conducted Community Dialogue Sessions facilitated by the trained traditional leaders on the dangers of child marriages.
3rd Phase: Joint community action to sustain interventions against child marriages: CYECE conducted interface forums with community stakeholders and children to lift cultural and religious practices which fuel child marriages.
**Lessons learned:** The project achieved the following outcomes;
- Improved knowledge and skills on SRHR among girls
- Girl's ability to deny and report forced marriages
- Increased girls enrolment in formal education
- 48 girls withdrawn from child marriages
- Modified/changed cultural practices
- Community leaders supporting girls SRHR and education
- Enforcement of bye laws against child marriages
- Girl child friendly policies and laws in place

**Conclusions/Next steps:** CYECE is very much convinced that community led approached to curb child marriages are the only tool for a successful and sustained community intervention. Empowering community leadership to champion SRHR interventions is very crucial and sustainable. The project managed to develop community Bye-Laws to end child marriages.

# ANALYSES OF CHANGES IN POLICY AND PRACTICE

## TUPEE517

### NATIONAL SURVEY OF UNITED STATES HIV HEALTHCARE PROVIDERS ABOUT AFFORDABLE CARE ACT KNOWLEDGE AND ATTITUDES

K.A. McManus[1], K.R. McManus[2], R. Dillingham[1]
*[1]University of Virginia, Infectious Diseases and International Health, Charlottesville, United States, [2]Royal College of Surgeons in Ireland, Dublin, Ireland*
*Presenting author email: km8jr@virginia.edu*

**Background:** The Affordable Care Act (ACA) has changed HIV healthcare delivery in the United States. The objective was to explore HIV providers' knowledge and attitudes about the ACA across the nation.
**Methods:** HIV providers were emailed a weblink to a survey. The survey assessed sources of ACA information, knowledge about the ACA as well as attitudes about the ACA.
**Results:** Of the 253 survey respondents, 16.2% were fellow physicians, 4.0% were PAs, 13.8% were NPs, and 66% were attending physicians. The respondents were from 35 of the 50 United States and the District of Columbia. 60.1% respondents were from Medicaid expansion states. In terms of sources of ACA knowledge, 63% reported using websites, 62.8% reported using newspapers/magazines, 44.7% reported using clinic case managers, and 34.8% reported using the radio. The majority of respondents (60.5%) answered all 4 knowledge questions correctly. Approximately one-third of respondents answered "I don't know" to at least one question. 70.8% knew whether or not their state had elected to expand Medicaid. On a scale

**Tuesday 19 July** Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

rating the ACA's impact from 1-5 with 5 as the best, the mean response for improving national health outcomes was 3.95 (SD: ±.95), for improving their patients' HIV outcomes was 3.61 overall (±.92; for Medicaid expansion: 3.78 (±.83), for Medicaid non-expansion: 3.37 (±1.00); Mann-Whitney U Test p =.002), and for improving their patients' non-HIV outcomes was 3.93 (±.90). In multivariate logistic regression, controlling for years of experience, sources of ACA information, and ACA attitudes, factors associated with correct ACA knowledge include: provider type (p=.011), provider in Medicaid non-expansion state (aOR 2.57; CI 1.30-5.10; p=.007), obtaining knowledge from
1) clinic case managers (aOR 2.88; CI 1.35-6.13; p=.006),
2) the radio (aOR 2.31; CI 1.02-5.23; p=.044),
3) newspapers/magazines (aOR 2.20; CI 1.00-4.81, p=.049), and
4) websites (aOR 2.12; CI 1.00-4.50; p=.050), and a positive attitude towards the ACA's effects on the United States' health outcomes (aOR 2.81; CI 1.58-5.02; p< .001).
**Conclusions:** Without Medicaid expansion, to protect people living with HIV with the lowest incomes, providers anticipate worse HIV outcomes. This survey reveals that providers retain accurate information about the ACA from the media and clinic case managers.

## TUPEE518

### HIV PCR TESTING AT BIRTH: EXPERIENCES FROM A REGIONAL HOSPITAL IN ETHEKWINI, KWAZULU-NATAL, SOUTH AFRICA

P. Naidoo[1], Z. Banoo[2], L. Ogle[1]
[1]*Maternal, Adolescent and Child Health Systems, Health Systems Strengthening, Durban, South Africa,* [2]*KZN Department of Health, DCST, Durban, South Africa*
*Presenting author email: prinaidoo@match.org.za*

**Background:** eThekwini district, KwaZulu-Natal (KZN),(population 3,4 million; ANC HIV sero-prevalence, 39%), South Africa has promoted PMTCT of HIV since 2002 and achieved an infant 1st PCR test positive around 6 weeks rate of 1.1% in 2014. However, HIV is still a significant contributor of < 5 mortality. Intrauterine infections present highest risk of rapidly progressive disease and death, and can be detected by birth HIV PCR testing. Survival benefit has been demonstrated when infected infants are initiated on ART before 14 weeks of age.
**Description:** In April 2015 KZN Department of Health adopted PCR testing within 6 hours of birth for all HIV-exposed infants and ART initiation within 7 days of diagnosis. This was communicated to facility management at a provincial workshop and district quarterly meetings, and facilities were requested to develop implementation plans. Review of a regional hospital June 2015 data by District Clinical Support Team (DCST) and MatCH, a PEPFAR-funded NGO, showed poor compliance - only 14% of eligible neonates were tested. Additional support visits were provided by DCST; and training and mentoring by MatCH on the amendment and PCR testing technique. Subsequent improvement in testing was noted with facility achieving up to 97% coverage (Table1).

| | June | July | August | September | October | November |
|---|---|---|---|---|---|---|
| Live birth to HIV positive woman | 234 | 249 | 221 | 163 | 181 | 216 |
| Birth PCRs tests | 33(14%) | 161(65%) | 191(86%) | 128(79%) | 176(97%) | 203(94%) |
| Birth PCR positive test | 0 | 1 | 8 | 3 | 0 | 0 |

*[Table1. Birth PCR testing at regional hospital (2015)]*

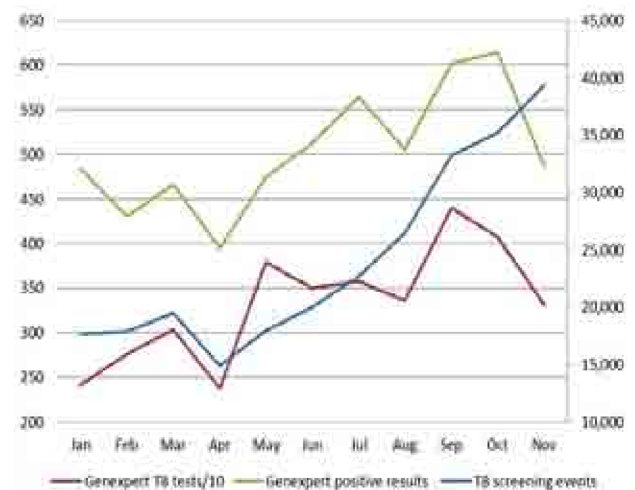
**Lessons learned:** National guideline was poorly adapted at facility level with lack of commitment from key role players. Guideline implementation needs to be incorporated into quality assurance processes and review mechanisms at facility level for prompt identification, using institution data as a foundation for quality improvement. Routine feedback mechanisms need to be in place to assess compliance to guidelines at district level with timelines specified.
**Conclusions/Next steps:** *Field and Lohr emphasized that 'guidelines do not implement themselves' (1992).* Advance planning for guideline dissemination will ensure better implementation of policies with specific roles and responsibilities clarified at facility level. Targeted intervention plans need to be in place with ongoing training and mentorship programmes to promptly address gaps identified.

## TUPEE519

### DOES INCREASED IN-FACILITY VERBAL TB SCREENING RESULT IN INCREASED TB CASE-FINDING? YES...AND MAYBE

D. Pienaar[1], L. Phillips[2], H. Mohamed[1], R. Dyers[1]
[1]*Western Cape Department of Health, Cape Town, South Africa,* [2]*Western Cape Department of Health, Worcester, South Africa*

**Background:** The District Health Services of the Western Cape made a concerted effort to increase TB verbal screening in PHC facilities in 2015. To facilitate the process, mid-level managers were required to focus on this activity; tools were developed for recording screening events and provincial monitoring systems were enabled. The results from one rural district are reported.
**Description:** In the Cape Winelands district the number of recorded verbal TB screening events in 2015 changed from an average 18,300 per month in the January-to-March period to an average of 35,900 in September to November, reflecting a 96% increase in the number of TB screening events.
Over the same periods, the number of recorded Genexpert tests changed from an average of ~2,700 per month to ~3,930 per month (44% increase), and the average number of positive Genexpert results changed from 460 per month to 568 per month (23% increase). Figure 1 elucidates:



*[Figure 1. TB screening vs TB testing vs positive TB results]*

Table 1 summarises the results per sub-district (all changes compare January-March to September-November):

| | Proportional increase in verbal screening events | Proportional increase in TB tests | Proportional increase in positive TB results |
|---|---|---|---|
| Sub-district 1 | 45% | 94% | 67% |
| Sub-district 2 | 412% | 22% | -7% |
| Sub-district 3 | 6% | 29% | 13% |
| Sub-district 4 | 143% | 21% | 21% |
| Sub-district 5 | 201% | 50% | 41% |
| WHOLE DISTRICT | 96% | 44% | 23% |

*[Table 1]*

**Lessons learned:** 23% more TB was diagnosed in September-November compared to January-March (an additional ~100 cases per month). Laboratory diagnosed TB cases correlated better with the number of tests submitted than the number of screening events.
**Conclusions/Next steps:** Increased verbal screening appears to increase laboratory TB diagnosis but further analysis is required to elaborate the relationship of both to the intermediate step of TB testing at facility level. These results are based on screening and laboratory data only. Genexpert might not the only testing modality. TB treatment data must be reviewed to assess whether a commensurate increase in treatment initiation is documented.

## TUPEE520

### MONITORING PHARMACY AND TEST KIT STOCKS IN RURAL MOZAMBIQUE: PREVENTING MINISTRY OF HEALTH STOCK-OUTS IN THE U.S. PRESIDENT'S EMERGENCY PLAN FOR AIDS RELIEF (PEPFAR)

M. Bravo[1], M. Blevins[2], A. Muicha[1], E. Mahagaja[3], F. Alvim[1], A.F. Green[1,4], C.W. Wester[1,5], S. Vermund[1,6]

*[1]Friends in Global Health, Maputo, Quelimane, Mozambique, [2]Vanderbilt University, Vanderbilt Institute for Global Health; Dept of Biostatistics, Nashville, United States, [3]Mozambican Ministry of Health, Provincial Health Directorate of Zambezia, Quelimane, Mozambique, [4]Vanderbilt University, Vanderbilt Institute for Global Health, Nashville, United States, [5]Vanderbilt University, Vanderbilt Institute for Global Health; Dept of Medicine, Nashville, United States, [6]Vanderbilt University, Vanderbilt Institute for Global Health; Dept of Pediatrics, Nashville, United States*
*Presenting author email: magdalena.bravo@fgh.org.mz*

**Background:** HIV and tuberculosis (TB) treatment scale-up in Mozambique has expanded very rapidly in the last couple of years. We assessed the central pharmacy experience for medications and test kits being used in Zambézia province, northcentral Mozambique, with the nation's second largest population and high HIV prevalence.
**Methods:** Using pharmacy stock surveillance for 60 weeks (April 2014-June 2015), we assessed availability of 36 medications (five medication classes) and four diagnostic kits (HIV and malaria rapid tests and syphilis RPR) used in PEPFAR-supported programs. Medication/kit classes were: adult antiretrovirals (ARVs), pediatric ARVs, TB medications, antibiotics, and test kits. We modeled pharmacy data using ordinal regression, characterizing weekly product availability in four categories: good; adequate; imminent stockout; or stockout.
**Results:** Among 2160 weekly records, there were 166 (7.7%) stockouts and 150 (6.9%) imminent risks of stockout. Earlier calendar time was associated with a reduced medication supply (p< 0.001), the time association was non-linear (p< 0.001), selected drug/kit classes were associated with reduced supply (p< 0.001), and an interaction effect existed between time and drug class on the odds of reduced supply (p< 0.001). At the evaluation's mid-point, pediatric ARVs had a 17.4 (95% confidence interval [CI]: 8.8-34.4) times higher odds of a reduced medication supply compared with adult ARVs. Compared with adult ARVs, TB medications, antibiotics and test kits were also at greater risk of reduced supply at the evaluation's mid-point. Adult and pediatric ARVs had 67% and 71% lower odds respectively of reduced medication supply over time (95%CI: 0.11-1.04 and 0.11-0.79), comparing the first and last weeks.
**Conclusions:** Despite increasing demand over time with program scale-up, adult ARV pharmacy shortages have become less frequent. Pediatric ARVs, TB medication, antibiotics, and test kits have been more prone to variable stock outs and will be a priority focus.

# IMPACT OF HIV FUNDING/PROGRAMMING ON REPRODUCTIVE HEALTH AND OTHER DISEASE OUTCOMES

## TUPEE521

### THE LARGEST EFFECT OF AN HIV QUALITY IMPROVEMENT PROGRAM IN CÔTE D'IVOIRE IS ON PROVISION OF MATERNAL HEALTH CARE

K. Ouattara[1], S.C. Stender[2], C. Nioble[1], O. Abiodun[3], L. Coulibaly[1], M. Toure[1], L.E. Abhe[4], K.A. Ekra[5]

*[1]Jhpiego, Côte d'Ivoire, Abidjan, Cote D'Ivoire, [2]Jhpiego, Cape Town, South Africa, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [4]Ministry of Health and Public Hygiene, Abidjan, Cote D'Ivoire, [5]Centers for Disease Control and Prevention, Abidjan, Cote D'Ivoire*
*Presenting author email: ouattara.kiyali@jhpiego.org*

**Background:** Cote d'Ivoire is likely to have met Millennium Development Goal (MDG) 6 to 'halt and have begun to reverse the spread of HIV/AIDS by 2015', yet MDG 5 - to reduce the maternal mortality ratio by three quarters between 1990 and 2015 - showed no progress. Improving health of individuals and communities requires a health-systems approach to ensure pregnant women living with HIV do not die of other preventable causes. Through funding from CDC/PEPFAR, in 2008 Jhpiego began implementing a quality improvement (QI) program across 35 health facilities with the aim of improving the quality of antenatal care (ANC), including preventing mother to child transmission (PMTCT) of HIV. An evaluation was undertaken to assess the effects on service delivery.
**Description:** The evaluation was a quasi-experimental, pre- post- design, undertaken in 10 health facilities offering ANC and PMTCT services in northern Cote d'Ivoire. Baseline and endline data collection occurred in March 2014 and February 2015, respectively. Data collection included observations of consultations with providers and data reviews. Data analysis was done using STATA.
**Lessons learned:** There was an improvement in HIV service delivery in ANC, with significantly more women provided education on the risk of transmission of HIV during pregnancy. The table shows the substantial improvement in provision of basic antenatal care, including educating women about danger signs during pregnancy and discussing post-partum family planning options.

| Service Delivery Standard Achieved | N Achieved / N Assessed at Baseline | N Achieved / N Assessed at Endline | p value | RR |
|---|---|---|---|---|
| Provider explains the risk of transmission of HIV from mother to child during pregnancy, labor & delivery, and breastfeeding | 41 / 136 (30%) | 108 / 140 (77%) | .008 | 2.56 (1.28 - 1.53) |
| Provider establishes the HIV status of the client | 96 / 136 (71%) | 122 / 125 (98%) | .006 | 1.39 (1.10 - 1.75) |
| Provider explains intermittent preventive treatment for malaria | 53 / 126 (42%) | 112/ 138 (81%) | .001 | 1.93 (1.29 - 2.88) |
| Provider encourages the woman to deliver in a health facility | 21 / 134 (16%) | 89 / 138 (64%) | .001 | 4.12 (1.95 - 8.69) |
| Provider discusses at least 4 danger signs during pregnancy: vaginal bleeding, intense headache, fever, acute abdominal pain, blurred vision, convulsions, shortness of breath | 7 / 135 (5%) | 92 / 140 (66%) | .001 | 12.67 (5.53 - 29.05) |
| Provider discusses family planning options | 4 / 135 (3%) | 61 / 139 (44%) | .002 | 14.81 (2.63 - 83.33) |

*[Improvements in provider performance in Antenatal Care]*

**Conclusions/Next steps:** The implementation of a QI program targeting PMTCT services led to significant improvements in the general management of pregnant women in ANC, as well as provision of PMTCT services. This is of particular importance in a setting where the leading causes of maternal mortality are hemorrhage, indirect causes, and eclampsia. Standardization of ANC and PMTCT services, using a health-systems focused QI approach, contributes to improvements in maternal health beyond HIV, perhaps most importantly the planning for the next pregnancy.

## TUPEE522

### THE IMPACT OF AIDS TREATMENT ON TUBERCULOSIS OUTCOMES AT THE NATIONAL LEVEL IN SOUTH AFRICA

Z. Mclaren[1], A. Sharp[1], E. Brouwer[1], A. Nanoo[2]

*[1]University of Michigan, School of Public Health, Ann Arbor, United States, [2]National TB Reference Laboratory, Johannesburg, South Africa*
*Presenting author email: zmclaren@umich.edu*

**Background:** HIV/TB co-infection is particularly prevalent in South Africa, where TB has been the leading cause of death for over a decade. The 2004-2008 national rollout of ART provides a unique opportunity to examine the population-level impact of ART on the TB epidemic.
**Methods:** We performed a longitudinal regression analysis that follows the evolution of TB outcomes before and after the introduction of ART using a large data set from the National Health Laboratory Service. This is the first study to produce estimates of the impact of the ART rollout net of confounders by exploiting the random variation in the rollout.
**Results:** After ART became available in a health facility, 3·7% (p< 0·0001) more patients were tested for TB and 3·2% (p< 0·0001) more received follow-up tests, with a steep rise around the introduction of ART. Though the number of TB-positive patients increased by 4·3% (p=0·0002) in the first year post-ART, the TB rate among tested patients fell by 2 percentage points (8%, p=0·001) after two years. Sputum smear testing declined relative to more technologically advanced diagnostics post-ART.
**Conclusions:** ART availability increased attention to TB screening and drew new patients into the health care system. Increases in the numbers of repeat patients are indicative of retention in care and reflect an increase both in TB screening and monitoring. The decline in TB rates post-ART demonstrates that the reduction in TB risk due to improved immune functioning and more contact with health care outweighed any increased TB risk due to the longer lifespan of ART initiators.

## TUPEE523

### BARRIERS TO COLLECTION OF MEDICO-LEGAL EVIDENCE IN RAPE CASES IMPACTS OF HIV PREVENTION AND CARE

P. Mungwari Mpani[1], A. Gibbs[2], F. Thindwa[1]
*[1]Tshwaranang Legal Advocacy Centre, Research and Advocacy, Johannesburg, South Africa, [2]University of KwaZulu Natal, HEARD Institute, Durban, South Africa*
*Presenting author email: patience@tlac.org.za*

**Background:** Evidence suggest that there is high prevalence of rape in South Africa, accompanied by poor reporting and low conviction rates for offenders. Medico-legal services play an important role, securing convictions and also in HIV prevention for victims of sexual violence in particular rape. Tshwaranang Legal Advocacy Centre and the Health Economics and HIV/AIDS Research Division (HEARD) at University of KwaZulu Natal carried out a study to explore the barriers to the collection and use of medico legal evidence in prosecution of sexual violence cases.
**Description:** The research was conducted in Gauteng, Eastern Cape, Mpumalanga and KwaZulu Natal. The sample included doctors and forensic nurses at health centres, forensic detectives within South African Police Services, specialist prosecutors, case managers and site coordinators at Thuthuzela Care Centres. Ethical approval for the study was given by the University of KwaZulu Natal Human and Social Science Research Ethics.
**Lessons learned:** Inadequate human and financial resourcing of targeted departments, contempt for survivors of violence, uneven knowledge and poor implementation of sexual assault procedures and policies and a lack of adequate knowledge by survivors to respond after a sexual assault in ways that safeguard evidence and reduce further harm to themselves. All these had the potential to undermine access to post exposure prophylaxis and some impacted on adherence to Anti-Retroviral Therapy.
**Conclusions/Next steps:** The need to advocate for adequate resourcing of the relevant government departments, to ensure that services required for survivors of violence are accessible and available. Gender sensitivity training and programmes for duty bearers, who are the first point of contact with survivors and are expected to ensure survivor get treatment to prevent infection. Awareness raising in communities on responding to sexual assault. It is envisaged that improving the medico legal services will in turn allow victims of rape to have confidence in the system and access post rape services timeously and, in so doing preventing exposure to such as HIV.

# EFFECTS OF HIV PROGRAMMING (PREVENTION AND TREATMENT) ON DEVELOPMENT OUTCOMES (E.G., SCHOOLING)

## TUPEE524

### INFLUENCE OF ANTIRETROVIRAL THERAPY ON NUTRITIONAL STATUS OF CHILDREN: ANALYSIS OF 21 GLOBAL PRIORITY COUNTRIES IN AFRICA

D.A. Adeyinka[1], E.A. Agogo[2], C.E. Ozigbu[1], E. Ngige[1], S. Aboje[1], S. Araoye[1], C. Anyaike[1], E.C. Asadu[1], E. Abatta[1], D. Odoh[1], O. Oladimeji[3,4], D. Chamla[5]
*[1]National AIDS & STI Control Programme, Federal Ministry of Health, Abuja, Nigeria, [2]National Agency for Control of AIDS (NACA), Abuja, Nigeria, [3]Centre for Community Health Care, Research and Development, Abuja, Nigeria, [4]College of Health Science, University of KwaZulu Natal, Department of Public Health Medicine, Durban, South Africa, [5]UNICEF HQ, New-York, United States*
*Presenting author email: nascp_adeydan@yahoo.com*

**Background:** The virological and immunological benefits of antiretroviral therapy (ART) in HIV-infected children have been widely studied. However, few studies have examined the effects of paediatric HIV interventions on malnutrition in Africa where 30-50% of children with severe acute malnutrition are HIV-infected. The purpose of this study was to determine the influence of paediatric HIV treatment on malnutrition in the 21 global priority countries in Africa.
**Methods:** This is an ecological study, which correlated country-level data on nutritional indicators (2007-2014) with paediatric ART coverage (2014) from WHO global database on child growth and malnutrition, and 2015 UNAIDS progress report on global AIDS epidemic plan. Data were analysed with STATA v.12.0. We explored the pattern of relationships with scatter plots. Pearson's correlation and linear regression were utilized to explore possible association and adjust for confounders. The β-coefficients were estimated based on the maximum likelihood method. A p-value of 0.05 was considered to be statistically significant.
**Results:** The mean paediatric ART coverage was 30.1% (SD: 6%) [Range 8%, Chad; 66%, Namibia]. The mean prevalence of the nutritional indicators among under-5 children were: wasting 6.8% (SD: 3.9%) [Range 0.8%, Swaziland; 18.1%, Nigeria]; underweight 16.7% (SD: 6.8%) [Range 5.8%, Swaziland; 30.3%, Chad] and stunting 35.3% (SD: 8.5%) [Range 22.7%, Ghana; 57.5%, Burundi]. Across the 21 countries, paediatric ART coverage had a highly significant inverse linear correlation with prevalence of wasting (r= -0.5, p=0.03) and underweight among under-5 children (r= -0.6, p=0.009). Although not significant, the prevalence of stunting was lower among countries with a higher paediatric ART coverage (r= -0.3, p=0.132). The regression analysis showed that for every 10% increase in paediatric ART coverage, there was a decrease of 1% in prevalence of wasting and 2% fall in prevalence of underweight. After adjusting for Gini coefficient, poverty index and gender inequality, paediatric ART coverage was the most important correlate with wasting
(β = -0.42; 95%CI: -0.8, -0.03; p=0.042).
**Conclusions:** Our findings suggest that increased paediatric ART coverage lowers the risk of acute malnutrition. To accelerate Sustainable Development Goal 2 on reducing the risk of child malnutrition in the countries, there should be more investments on paediatric ART programmes.

## TUPEE525

### DESIGN AND VALIDATION OF TEXT-MESSAGES FOR A MOBILE-HEALTH INTERVENTION TO IMPROVE ADHERENCE IN PEOPLE LIVING WITH HIV

I.N. Perez-Sanchez[1,2], N.P. Caballero Suárez[2], E. Rodríguez Estrada[2], C. Iglesias[2], G. Reyes-Terán[2]
*[1]National Council of Science and Technology CONACyT, Catedras CONACyT, Ciudad de México, Mexico, [2]National Institute of Respiratory Diseases, INER, Center of Research in Infection Diseases CIENI, Mexico City, Mexico*
*Presenting author email: ivonne.perez@cieni.org.mx*

**Background:** Mobile-health (mhealth) interventions, particulary those based on text-messages (SMS) can be cost-effective to increase antiretroviral treatment (ART) compliance. To ensure their effectiveness, SMS must be adjusted to the specific population of people living with HIV (PLWH). This study describe the design and validation of SMS to be used in a randomized-controlled study for a mHealth intervention aiming to improve ART adherence and decrease loss to follow up in PLWH in an HIV clinic in Mexico City
**Methods:** Eleven HIV-specialised health-care professionals (HCP) and 40 PLWH participated in this study. Data were collected from July to November 2015. Six HCP were asked to write 5 SMS for 4 categories: motivational self-healthcare SMS, reminders of ARV collection, medical and laboratory appointments. Then the SMS were judged by 5 different HCP based on: a) SMS match with the category (Yes/NO), b) SMS usefulness (0-10) and c) SMS fit for PLWH (0-10). We calculated two reliability measurements: judges' percent agreement (JA) and intraclass correlation coefficient (ICC). SMS were selected if they matched with the category and had usefulness and fit scores above 50 percentile. Lastly, SMS were tested in focus groups of PLWH, where participants commented on language and evaluated them based on: a) is the SMS understandable (Yes/No), b) SMS pleasantness (0-10) and c) SMS usefulness (0-10); JA and ICC were calculated. SMS were selected if they were understandable and had usefulness and pleasant scores over 50 percentile. We compared SMS scores by sex, age, disclosure and time since HIV diagnosis.
**Results:** 128 SMS were submitted and assessed by expert referees, obtaining mean JA=91.66%; usefulness ICC=0.30; and fit ICC=0.30. Eighty-six SMS with the highest scores were selected to be evaluated in focus-groups, and obtained a median JA of 97.36%; usefulness ICC=0.30; and fit ICC=0.31. Forty-eight SMS with the highest scores were retained. We found differences in SMS language preferences, pleasantness and usefulness scores, according to sex, age and time since HIV diagnosis
**Conclusions:** The validation process allowed us to obtain 48 well-accepted SMS that vary depending on age, sex and time since diagnosis. This process may be key in ensuring mHealth effectivenes.

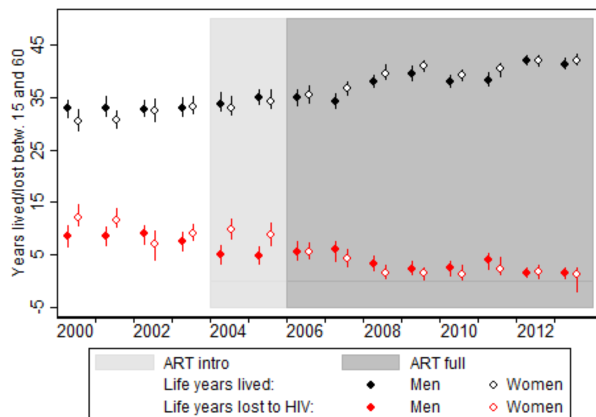
## TUPEE526

### POPULATION-WIDE ADULT MORTALITY FOLLOWING THE EXPANSION OF ANTIRETROVIRAL THERAPY PROGRAM IN THE RAKAI DISTRICT (UGANDA)

D. Nabukalu[1,2], G. Reniers[2,3], S. Blom[3], E. Slaymaker[2,3], B. Zaba[2,3], T. Lutalo[1,2]
*[1]Rakai Health Sciences Program, Data Management, Kampala, Uganda, [2]ALPHA Network, Population Health, London, United Kingdom, [3]London School of Hygiene and Tropical Medicine, Population Health, London, United Kingdom*
*Presenting author email: dnabukalu@rhsp.org*

**Background:** Studies have demonstrated the impact of ART on the survival of individuals enrolled in HIV care and treatment programs, but there is a scarcity of research evaluating the impact of ART at a population level.
**Methods:** Demographic and HIV surveillance data come from the Rakai Community Cohort Study (RCCS) for the period covering 1999 to 2013. We use non-parametric survival analysis for estimating trends in (i) the person-years lived in adulthood (ages

15-60) and (ii) the adult life-years lost to HIV. For testing differences in age-adjusted mortality hazards of people living with HIV (PLHIV) by gender, time and treatment status, we use parametric survival analysis with a Weibull distributed outcome.
**Results:** Since the introduction of ART in 2004, the per-person number of years lived in adulthood increased from 32.87 (95%CI: 31.24-34.58) to 42.08 (95%CI: 41.10-43.08) years for women and from 33.80 (95%CI 32.22-35.39) to 41.33 (95%CI: 40.14-42.43) years for men. As a result, the number of life-years lost to HIV in 2013 has declined to 1.27 years among women and 1.53 years among men (Figure 1). Reductions in the mortality rates of PLHIV (both on and off ART) explain most of these changes. Among PLHIV who received treatment, the risk of mortality was 2.4 times higher among men than among women (95%CI: 1.63-3.52), with no evidence of changing gender differences. Conversely, the mortality risk among untreated women decreased by 25% each calendar year (95%CI: 0.71-0.79) and among men there was a 15% annual decline (95%CI: 0.81-0.90).



*[Figure 1]*

**Conclusions:** The last decade is characterized by large reductions in HIV-associated mortality, and the residual burden of HIV on the adult mortality is now relatively small. Gender differences in the mortality rates of PLHIV are sizable and, in the case of pre-ART mortality, increasing over time. Increasingly expansive PMTCT services probably contribute to these gender differences.

## TUPEE527

### THE CAUSAL IMPACT OF ART INITIATION ON HOUSEHOLD FOOD SECURITY OVER TIME

B. Patenaude[1], N. Chimbindi[2], D. Pillay[2,3], T. Bärnighausen[1,2]
*[1]Harvard T.H. Chan School of Public Health, Global Health & Population, Boston, United States, [2]Africa Centre for Population Health, Mtubatuba, South Africa, [3]University College of London, Infection & Immunity, London, United Kingdom*
*Presenting author email: bnp706@mail.harvard.edu*

**Background:** The magnitude and direction of the net effects of ART on household welfare is unclear: patients may incur costs when utilizing ART (e.g., travel); conversely, patients recover health and employment on ART. This study examines the impact of ART on one aspect of household welfare - household food security.
**Methods:** We utilize routinely collected longitudinal data from the Africa Centre for Health and Population Studies and employ a regression discontinuity design over 2300 observations (collected between 2004 and 2012), to assess the causal impact of ART on three household-level food security outcomes: probability of an adult missing any food for financial reasons, probability of an adult missing a meal for financial reasons, and probability of a child missing a meal for financial reasons.
**Results:** For each outcome, ART causes a significant increase in the probability of food insecurity in the year immediately following ART initiation, which diminishes to 0 between 1 and 3 years after ART initiation. In the first year after initiation, ART initiation yields a significant increase in the probability of an adult in the household missing food by 11.3 percentage points (coefficient = 0.113, 95% CI = [0.044, 0.183]), a significant increase in the probability of an adult in the household missing a meal by 11.8 percentage points (coefficient = 0.118, 95% CI = [0.024, 0.213]), and a significant increase in the probability of a child in the household missing a meal by 9.4 percentage points (coefficient = 0.094, 95% CI = [0.033, 0.156]). The upper bound on these causal estimates is an approximately 6 fold increase in short-term household food insecurity as a result of ART initiation.
**Conclusions:** ART initially places a significant burden on household food security; however, this effect disappears over time. It is likely that rapid appetite recovery paired with the financial burden of utilizing ART, which are high relative to income in this community, initially outweigh the longer-term beneficial ART effects on employment and income. Food and financial support programs may help to alleviate the temporary loss in food security following ART initiation, especially in the context of the expanding ART rollout and treatment-as-prevention strategies.

# MICRO-ECONOMIC AND MACRO-ECONOMIC IMPACTS OF HIV PROGRAMMES AND POLICIES

## TUPEE528

### ONE SIZE WILL NOT FIT ALL: DIVERGENT PREFERENCES FOR NEW HIV PREVENTION PRODUCTS ACROSS ADULTS, ADOLESCENTS AND FEMALE SEX WORKERS IN SOUTH AFRICA

M. Quaife[1,2], R. Eakle[1,2], M. Cabrera[2], P. Vickerman[3], S. Delany-Moretlwe[2], F. Terris-Prestholt[1]
*[1]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom, [2]Wits RHI, University of the Witwatersrand, Johannesburg, South Africa, [3]University of Bristol, School of Social and Community Medicine, Bristol, United Kingdom*
*Presenting author email: matthew.quaife@lshtm.ac.uk*

**Background:** The development of antiretroviral (ARV)-based HIV prevention products has substantially changed the prevention landscape, yet little is known about how appealing these products will be to potential users. We conducted a discrete choice experiment (DCE) to measure preferences for oral, topical (intravaginal ring or gel with/without a diaphragm) or injectable ART-based pre-exposure prophylaxis.
**Methods:** From September to December 2015, we consented and interviewed 340 adults (182 males, 158 females) and 73 adolescent girls (aged 16-17 years) in a household survey, and 122 female sex workers (FSW) recruited in a respondent-driven sampling (RDS) survey in Ekurhuleni, South Africa. Respondents were asked to choose between three hypothetical products with varying attributes over ten choice sets, with an opt-out option. Choice sets were developed through literature review, qualitative interviews and extensive piloting with target populations. Data were analysed using nested and mixed logit models.
**Results:** Among all groups, the refusal rate for the survey was less than 1%. Although the injectable product was the most favoured product among all groups, preferences for other attributes varied substantially between and within populations. Female sex workers valued high HIV protection around twice as much as adult women (population preference weight ratio (PPWR): 1.87, p=0.04) and adolescent girls (PPWR: 2.14, p=0.02), whilst frequency of use was the key driver of demand among adult women. Adolescent girls were equally concerned with protection from HIV, pregnancy (PPWR: 0.76, p=0.2), and STIs (PPWR: 0.74, p=0.14). Adult males valued both HIV protection (PPWR: 9.35, P>0.01) and STI protection (PPWR: 9.31, p>0.01) around nine times more than pregnancy prevention, and were the only group to indicate that side-effects were important inhibitors of demand.
**Conclusions:** These results suggest that stimulating demand for new HIV prevention products may require a more a nuanced approach than simply developing highly effective products. STI and pregnancy prevention, alongside frequency of use, appears to substantially impact demand. A one- size-fits-all package is unlikely to be an effective or efficient means of delivering new prevention products across different populations. These results strengthen evidence calling for the development of multi-purpose technologies.

# INTERVENTIONS TO INCREASE DEMAND, UPTAKE AND RETENTION OF VULNERABLE AND KEY POPULATIONS FOR HIV PREVENTION AND CARE PROGRAMMES

## TUPEE529

### DOES PEER OUTREACH INCREASE HIV TESTING SELF-EFFICACY AND UPTAKE? EVALUATION OF THE LINK UP PROGRAM IN BANGLADESH BROTHELS

S. Hossain[1], N. Sultana[1], T. Hossain[1], B. Zieman[2], S. Roy[1], N. Pilgrim[2], R. Yasmin[3], N. Sadiq[4], E. Yam[2]
*[1]Population Council, Dhaka, Bangladesh, [2]Population Council, Washington, United States, [3]Marie Stopes Bangladesh, Dhaka, Bangladesh, [4]International HIV/AIDS Alliance, Dhaka, Bangladesh*
*Presenting author email: sharifhossain@popcouncil.org*

**Background:** In Bangladesh, brothels house thousands of female sex workers (FSWs) who are at elevated risk of HIV. As part of the global Link Up project, an HIV and sexual and reproductive health peer outreach intervention was introduced in selected brothels. This analysis examines whether Link Up had an impact on FSWs' HIV testing self-efficacy and uptake.
**Methods:** A repeated cross-sectional survey was conducted before and after the intervention (June 2014 and August 2015) with all resident FSWs ages 18 to 24 in four intervention and four comparison sites. The survey collected information on

Tuesday 19 July Poster Exhibition
Wednesday 20 July
Thursday 21 July
Friday 22 July
Late Breaker Posters
Author Index

socio-demographics, HIV-related behaviors, healthcare utilization, and healthcare-seeking self-efficacy. Linear regression models assessed changes in HIV testing uptake (i.e., ever tested), receipt of test results, or testing self-efficacy (defined as confidence to locate a testing site and to get tested) from baseline to endline, comparing intervention and comparison brothels. Supplemental logistic regression models used endline data to compare these three outcomes among women who reported contact with a Link Up peer educator, relative to those with no such contact. All analyses controlled for clustering at the brothel level.

**Results:** Interviewers surveyed 1,061 baseline participants (505 intervention, 556 comparison), and 1,005 endline participants (541 intervention, 474 comparison). Testing uptake, receipt of test results, and testing self-efficacy increased over time in both intervention and comparison sites. However, in multivariate analyses, the improvement in intervention sites was not significantly different from that of comparison sites.

At endline, 68% of women in intervention brothels reported having contact with a Link Up peer educator. Women with peer educator contact had statistically significantly higher odds of testing uptake (Adjusted odds ratio [AOR] 1.76, 95% confidence interval [CI]: 1.04-2.96), receipt of test results (AOR: 6.56, 95% CI: 1.79-24.12), and testing self-efficacy (AOR 1.85, 95% CI: 1.25-2.73).

**Conclusions:** FSWs' testing self-efficacy and uptake increased over time, irrespective of whether they resided in brothels that received the Link Up program. Concurrent interventions in comparison sites may explain this finding. Furthermore, since testing self-efficacy and uptake increased more among those who had contact with Link Up peer educators, the intervention may have benefitted from increased outreach intensity to reach more residents.

## TUPEE530

### PROTECTION OF PLHIV'S ACCESS TO MEDICAL SERVICES AT PENAL INSTITUTIONS THROUGH THE NATIONAL PREVENTIVE MECHANISM

O. Gatiiatullin[1], V. Obolentseva[2]
*[1]All-Ukrainian Network of PLWH, Kyev, Ukraine, [2]Secretariat of the Ukrainian Parliament Commissioner for Human Rights, Kiev, Ukraine*
*Presenting author email: artullin@gmail.com*

**Background:** In 2006, Ukraine ratified the Optional Protocol to the Convention against Torture and other Cruel, Inhuman or Degrading Treatment or Punishment and undertook to establish a structure which would perform the functions of the National Preventive Mechanism (NPM). In 2012, the country introduced amendments to the Law of Ukraine "On the Commissioner for Human Rights of the Parliament of Ukraine", according to which functions of NPM were assigned to the Ombudsman's Office. Ukraine decided to apply the Ombudsman Plus Model. "Plus" means the civil society; the monitors, who have to become actively involved in monitoring visits to closed institutions.

**Description:** The All-Ukrainian Network of PLWHA joined the implementation of the NPM by its work in the expert council and involvement in monitoring visits to penal institutions. In 2015, the NPM monitors were engaged in works aimed at studying the access to medical services of people living with HIV at penal institutions in 9 regions of Ukraine. The instruments were provided and the peculiarities of the monitoring of ensuring the PLHIV's right for medical aid at penal institutions were taught. According to the results of the visits, the following systematic problems were found: a low level of prisoners' examinations to detect HIV (below 10% of the total number of prisoners); improper voluntary consultations and HIV testing; untimely examinations of HIV positive persons and prescription of antiretroviral therapy; a low qualification level of medical staff in terms of HIV/AIDS. Besides, the monitoring detected issuance of outdated antiretroviral medicines to convicts.

**Lessons learned:** Recommendations based on the detected violations, which could be fulfilled by penal institutions' managers, were fulfilled immediately. In case violations had a systematic character, they were reflected in reports. Based on the NPM monitors' reports, the Ombudsperson of Ukraine sent response acts to the Ministry of Justice of Ukraine and the State Penal Service of Ukraine.

**Conclusions/Next steps:** As a result of the project, the Ombudsperson's Office is initiating legislative amendments through preparation of a special report "Status of fulfillmentof the right for medical aid of PLHIV at institutions of the State Penal Service of Ukraine in 2015" for the parliamentary hearings.

## TUPEE531

### SUCCESSFUL KEY POPULATION PROJECT START UP IN A SOCIALLY, CULTURALLY AND LEGALLY SENSITIVE COUNTRY - BUY IN OF LINKAGES PROJECT FOR FEMALE SEX WORKERS AND MSM IN MALAWI

M. Ruberintwari[1], G. Kamanga[2], D. Chilongozi[2]
*[1]FHI 360, HIV Linkages, Lilongwe, Malawi, [2]FHI 360, HIV LINKAGES, Lilongwe, Malawi*
*Presenting author email: mruberintwari@fhi360.org*

**Background:** Key population (KP) such as female Sex Workers (FSW), men who have sex with men (MSM), have an important role in HIV/AIDS because of their increased risk and vulnerability. This is fueled by a combination of socio-political and structural barriers. Malawi is one of the high HIV/AIDS burden countries among general population and KP. The prevalence of HIV among FSW and MSM is high, 62.7 and 17.5% respectively and national prevalence is 10.6%. Projects addressing KP to reduce HIV transmission are therefore warranted.

**Description:** FHI 360 in Malawi with support from PEPFAR/USAID is implementing a five year Project for KP. The aim is to support the Government and KP organizations to meaningfully deliver interventions to reduce HIV transmission and acquisition among KP and extend life for those who are HIV-positive. We conducted several project entry meetings with leadership from Ministry of Health headquarters, National AIDS Commission, Central Hospitals, District Health Management, District Executive Committees and other stakeholders. We present a successful buy in approach amid prevailing barriers.

**Lessons learned:** It was initially difficult to convince some of the senior health leadership and other stakeholders in the four operational districts to support operations of KP project, but succeeded. KP Project was viewed as "promoting sex work and gay marriage rights" which is against the social-legal and moral norms of Malawi. The magnitude and or existence of FSW, MSM respectively has been a general subject of debate in Malawi, with some people thinking these groups are insignificant to cause public health concern, being unaware of the high prevalence. We used evidence based and sound advocacy skills used to secure the buy in. The emphasis was on health rights, the sexual interaction dynamics between KP and general public regarding HIV/AIDS. The official commitment of the Government of Malawi towards HIV prevention among key population was also our leverage point.

**Conclusions/Next steps:**

- Sensitive projects require pragmatic, informative and non-confrontational approaches to have buy in, by stakeholders.
- There should be meaningful involvement of opinion leaders to gain acceptance of projects.
- Build on documented government commitment to move forward sensitive programs.

## TUPEE532

### AN INDICATION OF EARLY SUCCESS OF KEY POPULATION PEER-LED INITIATIVES TO REACH, TEST AND TREAT FOR FEMALE SEX WORKERS

G. Kumwenda[1], S. Kalyati[2], M. Kamtimaleka[3], E. Changamire[3], S. Sikwese[3], B. Kapenuka[3], E. Nyirenda[3]
*[1]Pakachere Institute for Health and Development Communication, Blantyre, Malawi, [2]Pakachere IHDC, Monitoriting and Evaluation, Blantyre, Malawi, [3]Pakachere IHDC, Programmes, Blantyre, Malawi*
*Presenting author email: gkumwenda@pakachere.org*

**Background:** HIV prevalence among female sex workers (FSWs) in Malawi is estimated to be 62.7% compared to an estimated 10.6% in the general population. FSWs serve clients from the general population and therefore are a critical group in the spread of HIV in a population. Malawi has adopted the UNAIDS 90-90-90 target to provide a continuum of HIV care services to HIV infected individuals. PIHDC is implementing an intervention project among FSWs, LINKAGES HIV prevention, care and treatment which is supported by USAID. The aim of the intervention is to reduce HIV transmission among FSWs and improve the quality of life of key populations (KP) living with HIV. Clients are followed through the HIV cascade framework of reach, test, treat and retain (on ART).

**Methods:** It is a follow-up design project. We identified FSWs who mobilized their peers from their hotspots. FSWs were asked to select peer educators who were trained to reach up to 40 peers each with behavior change messages that promote HTC, STIs, gender based violence, family planning screening and PMTCT. All those reached through trained peer educators were linked to access care through outreach, mobile clinics and health facilities. In addition, we engaged peer navigators (HIV+ve FSW) to support HIV+ve peers to enroll and retain them on treatment.

**Results:** Of the 1284 FSWs reached, 191 were tested for HIV between October and December 2015. Of those tested 47% (N= 90) were HIV +ve and 87.7% (79) were enrolled in care (pre-ART) while 80% (63) were initiated on treatment. 8 default-

ers were identified and were successfully put on ART again after being identified through our peer led strategy.
**Conclusions:** Implementing the LINKAGES HIV cascade framework provides early insights, a pointer to a successful program guiding KP interventions towards the 90-90-90 target among FSWs. Involvement of FSWs peers help to get new enrollees for prevention, care, and treatment and bring back those non-adherent to intervention in the HIV service cascade.

## TUPEE533

### AFRICA KEY POPULATION EXPERTS GROUP: SEX WORKERS, MEN WHO HAVE SEX WITH MEN, TRANSGENDER PERSONS AND PEOPLE WHO USE DRUGS TAKE A LEAD IN PROVIDING STRATEGIC DIRECTION TO THE HIV RESPONSE IN AFRICA

N. Bondyopadhyay[1], M.G. Haileyesus[2], T. Sellers[2], J. Kashiha[3], M. Mbodj[4], P. Abdalla[5]
*[1]Private Public Heath Expert/Consultant, Addis Ababa, Ethiopia, [2]UNDP RSC Africa, Addis Ababa, Ethiopia, [3]Community Health Education Services and Advocacy, Dar es Salam, Tanzania, United Republic of, [4]Association Santé Espoir Vie, Dakar, Senegal, [5]Keswa, Nairobi, Kenya*
*Presenting author email: phelisterabdalla@yahoo.com*

**Background:** Despite significant progress in reducing HIV infections and expanding treatment in Africa, hostile legal and social environments have resulted in sex workers (SWs), men who have sex with men (MSM), transgender people (TGs) and people who use drugs (PWUDs) being disproportionately affected by HIV. As changing this situation requires, amongst other things, enhanced engagement of these groups at policy and strategy level, in 2014 UNDP supported the establishment of the Africa Key Population Experts Group.
**Description:** The Experts Group is comprised of around fifty MSM, TGs, PWUD and SWs drawn from sixteen African countries. Members are selected to the group in their individual capacity on the basis of their policy and programme expertise in HIV prevention and promoting human rights for KPs but they do not represent either their countries or the organizations and networks that they belong to. The group operates through regular face to face meetings as well as virtual electronic communication and have conducted three meetings between May 2014 and May 2015.
**Lessons learned:** Although identifying enough number of TGs and PWUDs has been challenging, the Experts Group is the first group that brings together these four KPs for collective advocacy, capacity development and skills building and provides a unique platform which significantly enhances their capacity to engage in important policy and strategy processes at regional, national and sub-national levels. The main achievement of the group to date has been the development of a Model Regional Strategic Framework on HIV for KPs which has been extensively used in fifteen countries as input into Global Fund processes, National Strategy reviews, research design, national reports, conferences, etc. and by two Regional Economic Communities, SADC and the EAC. The group also acts as the Regional Advisory Group for the new Africa Regional Global Fund Project on Human Rights.
**Conclusions/Next steps:** The Experts Group has a proven potential to serve as a reference group for KP focused policy and strategy review across Africa and could play an important role in setting standards for programming. It can also mentor the establishment of similar groups in other regions and foster cross-key population collaboration at the global level.

## TUPEE534

### DROP-IN CENTERS DRIVE HIGHER YIELD AND BETTER LINKAGE TO TREATMENT FOR FSWS IN ETHIOPIA

E. Workalemhu, W. Girma, G. Mamo
*Population Services International Ethiopia (PSI/E), Addis Ababa, Ethiopia*
*Presenting author email: wgirma@psiet.org*

**Background:** MULU is a USAID-funded HIV prevention project focused on key and priority Populations in Ethiopia. Female sex workers (FSWs) are highly marginalized and underserved population with an HIV prevalence of 24%, 16 times higher than the prevalence among women in the general population. Drop-In Centers (DICs), which provide social support, HIV testing, and linkage to treatment services have been an effective strategy to identify and link FSW with care, and diagnose HIV-positive FSWs.
**Description:** The project established 54 DICs in areas with a high density of FSW in towns with more than 500 sex workers. All DICs were licensed by the local government to provide clinical services including HIV testing services and linkage to treatment. The DICs were established with standard operating procedures to ensure MARPs friendliness in terms of access, provider attitude, confidentiality and availability of services. HIV testing results were analyzed from registrations anonymously. Referrals and linkage to treatment were tracked using a labelled voucher system, and completed vouchers were collected from the MULU clinic network of public and private facilities that provide HIV treatment.
**Lessons learned:** A total of 25,068 FSWs received HIV testing services at DICs between Oct., 2014-Sept, 2015. Altogether 802 women were diagnosed with HIV, for a yield of 3.2%. While this yield was significantly higher than the HIV prevalence in the general population, it fell short of the estimated 24% prevalence among FSW and higher than the 0.5% incidence among general women population. Approximately 80% of the women diagnosed with HIV in the DICs were successfully linked with treatment. The DICs are a useful entry points to identify new HIV cases and link them to treatment, with the goal of reducing HIV transmission and improving health of FSWs.
**Conclusions/Next steps:** Antiretroviral therapy initiation will benefit the health of sex workers and reduce the risk of HIV transmission to their clients and sexual partners. Investment in and expansion of the DIC model is important if Ethiopia is to scale up testing and treatment and improve linkage to treatment among FSWs. DICs act as FSW-friendly hubs, and help improve the health for a marginalized target populations with high HIV burdens.

## TUPEE535

### INCREASING HEPATITIS C KNOWLEDGE AMONG DRUG USERS ENGAGED IN METHADONE TREATMENT IN MALAYSIA

T. Mukherjee, V. Pillai, S.H. Ali, N. Ata, A. Kamarulzaman
*University of Malaya, Centre of Excellence for Research in AIDS (CERiA), Kuala Lumpur, Malaysia*
*Presenting author email: tmukher1@gmail.com*

**Background:** Hepatitis C (HCV) disproportionately affects people who inject drugs (PWIDs). Many misconceptions about HCV transmission exist among PWIDs, and overall knowledge, perceived risk and treatment interest is limited. Moreover, methadone has been shown to reduce risky behaviors responsible for transmitting HCV, and methadone clinics provide an opportunity to integrate HCV screening, education and treatment referrals. Therefore, the aim of this study is to determine baseline HCV knowledge and assess the impact of HCV education among PWIDs engaged in methadone treatment.
**Methods:** We enrolled 98 participants who routinely attended a methadone clinic in Malaysia. All participants completed a 1-hour standardized education session, socio-demographic questionnaires, and an HCV knowledge assessment at three time points: baseline, immediately after, and 4-weeks after the session.
**Results:** The mean age and dose of methadone are 44.5 (9.41) years and 115 (63.09) mg, respectively. The majority of participants are male (92.9%), employed full-time (56.1%), and have a history of injection drug use (74.5%). 24.5% are HIV-positive, 65.3% have been screened for HCV, and 16.3% are currently undergoing HCV treatment. At baseline, only 34.7% and 45.9% knew they could receive HCV treatment if HIV-positive or while on methadone, respectively. 25.5% knew that bleach, boiling water or alcohol would not sterilize needles against HCV, 32.7% knew that HCV re-infection could occur, and 53.1% were aware that no-cost treatment was provided at public hospitals. Perceived barriers to treatment included: not knowing where to go (35.7%), expensive medications (15.3%), and lengthy treatment durations (16.3%). Out of a possible 40 points, the average baseline score was 14.81 (8.45). Immediately after the session, scores increased 82.4% to an average of 27.02 (7.86; $p< 0.001$), and knowledge was retained with an average score of 24.32 (7.83; $p=0.001$) 4-weeks after the session.
**Conclusions:** This study shows that knowledge and HCV screening is low among PWIDs engaged in methadone treatment in Malaysia. A brief, but comprehensive HCV education session is a low-cost and effective strategy in improving overall HCV knowledge, making it suitable for resource poor settings. Thus, integrating HCV education into harm reduction programs may reduce HCV disparities, and increase screening and treatment interest in this high-risk population.

## TUPEE536

### HIV OUTREACH FOR FEMALE SEX WORKERS INCREASES UPTAKE OF HIV TESTING

C. Pitter[1], S. Khun[1], S.H. Lon[2], S. Seng[2], H.S. Tith[3], N. Sorn[4]
*[1]USAID HIV Innovate and Evaluate Project, University Research Co. LLC, Phnom Penh, Cambodia, [2]Cambodia National Centre for HIV/AIDS, Dermatology and STI Control, Phnom Penh, Cambodia, [3]Khmer HIV/AIDS NGO Alliance, Phnom Penh, Cambodia, [4]FHI 360, Phnom Penh, Cambodia*
*Presenting author email: cpitter@urc-chs.com*

**Background:** With one of the highest HIV prevalence rates in Southeast Asia, Cambodia's HIV epidemic response is focused on key populations, including female sex workers (FSW). Interventions to counter HIV among FSW include the SMARTgirl program which provides targeted outreach, including HIV/STI prevention education,

condom/lubricant promotion, and HIV/STI screening referrals. We evaluated the effects of the program on uptake of HIV testing among FSW.
**Methods:** In May-June 2015, we conducted cross-sectional survey of 1,176 FSW aged ≥ 18 years that received outreach services in seven geographic regions, collecting sociodemographic and service utilization data, selecting FSW using probability proportional to the size of the entertainment establishments where they worked. Binary logistic regression was used to identify the effects of outreach on uptake of HIV testing in the last 12 months, controlling for sociodemographic variables.
**Results:** Overall, 84% of FSW in the program were tested for HIV in the previous 12 months. The odds of having had an HIV test in the previous 12 months were higher for FSW that: received information about HIV testing and condom use from program outreach workers in the past 12 months (OR=6.74, p< 0.001), received a referral slip for FP services from outreach workers (OR= 2.1, p< 0.001), or received HIV/AIDS information from facility-based FP service providers in the past 12 months (OR=4.1, p< .01).
**Conclusions:** These findings show a high overall rate of uptake of HIV testing among FSW in the program (84%); more than the national DHS estimate of 70% of Cambodian FSW that were tested for HIV in the past 12 months in 2013. The findings also suggest the value of outreach on uptake of HIV testing among FSW. Key drivers of increased uptake of HIV testing were the provision of HIV-related information (by facility-based FP staff that were not part of the program, and by outreach workers that were) and referrals for FP services by outreach workers, which brought FSW to facilities that also provided HIV testing.

## TUPEE537

### FROM BROTHELS TO PARLIAMENT: LESSONS LEARNT FROM SCALING UP A RIGHTS-BASED SEX WORKER HIV PROGRAMME

M. Stacey[1], J. Rangasami[2], S.-J. Shackleton[3]
*[1]NACOSA, Key Populations, Cape Town, South Africa, [2]Impact Consulting, Cape Town, South Africa, [3]Sex Worker Education and Advocacy Taskforce (SWEAT), Cape Town, South Africa*
*Presenting author email: maria@nacosa.org.za*

**Background:** The HIV risk that sex workers face universally is heightened by contextual factors in South Africa, including a generalised epidemic, criminalisation and high rates of violence. The Red Umbrella Programme is a national peer-led combination prevention programme managed by NACOSA, funded by the Global Fund. Whilst the foundation of the programme is bio-behavioural interventions, the programme also includes structural interventions, including collective mobilisation; skills development; and interventions to reduce stigma and discrimination.
**Description:** The Red Umbrella Programme was implemented from October 2013-March 2016, by 19 civil society organisations. 616 sex worker peer motivators were employed to conduct Outreach, HCT and Risk Reduction workshops at 74 sites, in all 9 provinces. A 24-hour, national toll-free helpline is operated by sex worker counsellors. Leading sub-recipient SWEAT, implemented structural interventions to create an enabling environment, including sex worker capacity-building; sensitisation of stakeholders, social mobilisation via Sisonke Sex Worker Movement; and strengthening of sex workers' participation in HIV coordinating structures.
**Lessons learned:** Results are reported from three sources:
1) *Programme Data*: to date, 24 825 sex workers have tested for HIV;
2) *Good Practice Guide:* the results of a workshop that was held to assess how sex worker site coordinators had tailored the programme to their local contexts was published and;
3) *Programme Evaluation:* the evaluation (in press) will compare sex workers' current knowledge and behaviour with the results of a 2013 survey.
**Conclusions/Next steps:** For Phase III, the programme has integrated lessons learnt from stakeholders with evolving disease and treatment trends. The health component will be strengthened; referral for ART will be added. Phase III aims to improve data management further so that incidence and prevalence can be measured. However, activities related to creating a legally and socially enabling environment have been discontinued. An up-scaled, coordinated response to the violation of sex workers' rights remains a challenge.

## TUPEE538

### JOINT PEPFAR/GLOBAL FUND KEY POPULATION CASCADE ASSESSMENT IN MALAWI

R.C. Wolf[1], T. Lillie[2], J. Zhou[3], J. Edwards[4], R. Steen[5], M. Herce[6], K. Klindera[1], M. Ruberintwari[7]
*[1]USAID, Office of HIV/AIDS, Washington, United States, [2]FHI 360, LINKAGES Project, DC, United States, [3]The Global Fund, Technical Advise and Partnertships, Geneva, Switzerland, [4]UNC Chapel Hill, Chapel Hill, United States, [5]Erasmus University MC Rotterdam, Rotterdam, Netherlands, [6]UNC Chapel Hill, Lusaka, Zambia, [7]FHI 360, LINKAGES Project, Lilongwe, Malawi*
*Presenting author email: camwolf@aol.com*

**Background:** HIV programming for key populations (KP) - including men who have sex with men and sex workers - demands new and innovative tools for monitoring uptake of services, identifying gaps, and addressing structural barriers. The "HIV cascade" provides a useful conceptual tool for understanding population-level engagement within three stages of prevention and five stages of care and treatment. Through routine data collection, KPs can be monitored for "leaks" along the cascade to inform program improvement. In February 2016, a Joint Global Fund/PEPFAR Cascade Assessment was conducted in Malawi, through the LINKAGES project, to describe the HIV cascade for KP, identify "leaks" across the cascade, and refine LINKAGES and Global Fund interventions.
**Description:** The joint team reviewed available LINKAGES programmatic and clinical data, and met with representatives of government, KP community-based organizations, and health facilities to better understand the needs of KPs, and the facilitators and barriers to increased service access and availability.
**Lessons learned:** As Malawi moves toward comprehensive HIV/AIDS programming for KPs, implementers must reorient prevention, treatment and care models to include both community- and facility-based services. LINKAGES utilized micro-planning at the community level to map hot spot venues and generate size estimates to guide programming, including development of peer educator ratios to enable scalable KP outreach. In the first quarter of implementation, LINKAGES estimated 2,625 female sex workers (FSW) in Lilongwe, and reached 685 with community-based prevention services (26%). Of the 685, 279 were HIV-positive (41%). However, only 28 (10%) were documented as being enrolled in care. Pervasive human rights abuses, stigma and discrimination, and gender-based violence hinder demand for and accessibility to comprehensive HIV services. New programmatic interventions, including establishment of drop in centers providing ART, access to test and start ART, and peer navigator systems are planned to reach additional KP, increase uptake of HIV testing, and improve linkage to care and treatment.
**Conclusions/Next steps:** Joint PEPFAR/Global Fund Cascade Assessments are aligning available programmatic and clinical data sources to evaluate and improve community- and facility-based HIV/AIDS services for KP. Joint assessments are an emerging global best practice that can be replicated in other countries.

## TUPEE539

### PERCEIVED BARRIERS AND FACILITATORS TO COMBINING DELIVERY OF HIV PREVENTION, TESTING AND TREATMENT SERVICES WITH FEMINIZING HORMONE THERAPY FOR TRANSGENDER WOMEN IN LIMA, PERU

S.L. Reisner[1,2,3], A. Perez-Brumer[4], J.R. Lama[5,6], A. Silva-Santisteban[7], S.A. McLean[1], L. Huerta[8], R. de la Grecca[5], J. Sanchez[5,6], K.H. Mayer[1]
*[1]The Fenway Institute, Fenway Health, Boston, United States, [2]Boston Children's Hospital and Harvard Medical School, Division of General Pediatrics, Boston, United States, [3]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [4]Columbia University Mailman School of Public Health, Department of Sociomedical Sciences, New York, United States, [5]Asociación Civil Impacta Salud y Educación, Lima, Peru, [6]University of Washington, Department of Global Health, Seattle, United States, [7]Universidad Peruana Cayetano Heredia, Lima, Peru, [8]Epicentro, Lima, Peru*

**Background:** Transgender women (TW) represent a population at-risk for HIV infection in Peru. Holistic HIV prevention, testing, and treatment interventions that are responsive to the lived realities of TW and healthcare providers serving them are urgently needed. The current study gathered perspectives from healthcare professionals and TW in Peru to inform future community-based intervention approaches, including potential acceptability of combining HIV services with gender-affirmative medical care (e.g. cross-sex hormone therapy).
**Methods:** A mixed-methods study was conducted in January-February 2015 in Lima, Peru consisting of focus groups (FGs) and a brief survey. Seven FGs were conducted: two with healthcare professionals (N=19) and five with TW (N=48). FG transcripts were double-coded and analyzed utilizing an immersion crystallization approach to identify themes; descriptive analyses of survey data were conducted.
**Results:** Healthcare professionals (53% cisgender female; mean age=39 years) represented a variety of professions: 16% doctor, 26% nurse, 21% psychologist, 11% obstetrician, 26% other. Overall, TW (mean age=29 years) were at high-risk for HIV;

67% self-identified as a sex worker and 29% were unsure of their HIV status.
TW participants described hormones as a crucial step in gender affirmation; however, the majority of TW narratives described using hormones without medical consultation and under the guidance of friends/community members. Healthcare professionals echoed the importance of hormones to TW patients and lack of routine medical supervision.
Perceived acceptability of integrating hormone therapy with HIV services was high; more than 90% of healthcare professionals and TW perceived that such an approach would "very likely" improve the HIV cascade of care for TW. Nevertheless, participants identified implementation barriers: (1) medical mistrust felt by TW; (2) lack of training/guidelines to inform providers in hormone administration; (3) anticipated stigma by healthcare professionals for providing care to TW; (4) service delivery barriers. Healthcare professional and TW participants identified TW peer health promoters as essential resources to facilitate this intervention.
**Conclusions:** Feminizing hormone therapy represents a key need for many TW; however, delivery of such care is rarely considered alongside HIV services. This study found high levels of perceived acceptability for an integrated service model combining HIV prevention, care, and treatment services with delivery of hormones.

## TUPEE540

### HIV CASCADE OF CARE AMONG PEOPLE WHO USE DRUGS IN VIETNAM: FINAL GAPS AND FUTURE STRATEGY

H. Thi Duong[1], O. Khuat Thi Hai[2], K. Pham Minh[1], G. Hoang Thi[1], M. Peries[3], R. Vallo[3], L. Michel[4], T. Thi Nguyen[5], V. Vu Hai[6], T. Nham Thi Tuyet[2], P. Tabernero[3], J.-P. Moles[3], D. Laureillard[3], D. Des Jarlais[7], N. Nagot[3], DRIVE Study Group
*[1]Hai Phong Medical University, Hai Phong, Vietnam, [2]SCDI, Hanoi, Vietnam, [3]University of Montpellier, Montpellier, France, [4]INSERM U1178, Paris, France, [5]Provincial AIDS Department, Hai Phong, Vietnam, [6]Viettiep Hospital, Department of Infectious Diseases, Hai Phong, Vietnam, [7]Mount Sinai Beth Israel, New York, United States*
*Presenting author email: duonghuong2001@gmail.com*

**Background:** In Vietnam, the HIV epidemic has been driven by drug injection. Despite major efforts on risk reductions, rapid HIV elimination will require a high coverage of suppressive ART within people who inject drugs (PWID). Our study aimed at assessing the cascade of HIV care and to estimate the current HIV incidence among active PWID in Hai Phong (2 million inhabitants).
**Methods:** We conducted a community-based Respondent Driven Sampling (RDS) survey in May 2014, recruiting active users with positive urinary drug tests. After a standardised questionnaire, blood was drawn for HIV testing, CD4 count and HIV viral load when appropriate. Then, 250 RDS participants were enrolled in a longitudinal study with follow-up at week 12, 24 and 52 including HIV tests. Participants were supported by trained peers to register at methadone and HIV clinics.
**Results:** At the RDS survey, 603 participants were recruited in 3 weeks including 8% MSM, 7% FSW, 15% early-injectors (< 2 years injection) and 69% of "regular injectors". Heroin was the only injected drug. HIV and HCV prevalence was 25.2% and 66.8%, respectively. Of the 152 HIV-infected participants, 82 (53%) reported knowing their HIV status and of those 71 (86.6%) should have received ART according to national guidelines at the time (CD4 count< 350 cells/µL). Among the latter, 59 (83.1%) were already on ART and 49 of them (83.1%) had undetectable viral load. The follow-up rate was 86% at week 24 and 78% at week 52, with a mortality rate of 3.4/100 pers-years. At 52 weeks, 118 (58%) participants could be initiated on methadone and 52% on ART. No HIV seroconversion was recorded, giving a population HIV incidence between 0 and 1.8/100 pers-years.
**Conclusions:** In Hai Phong, the HIV cascade of care highlights a major gap in HIV testing among PWID. HIV-infected PWID tend to consult HIV services only when they are symptomatic, although with a satisfactory ART efficacy. Repeated community-based RDS as a mass screening strategy followed by peer-groups support in engaging PWID into HIV care (and methadone) would likely end the HIV epidemic among PWID in Haiphong. The low HIV incidence is encouraging towards this goal.

## TUPEE541

### EXPERIENCES OF PROVIDER DISCRIMINATION IN ACCESSING MEDICAL AND HIV PREVENTION SERVICES BY MEN WHO HAVE SEX WITH MEN INCLUDING TRANSGENDER MEN GLOBALLY

T.D. Do[1,2], G.-M. Santos[1,3], S. Arreola[4,5], A.I. Scheim[6], G. Ayala[4], MSMGF Research Group
*[1]University of California, San Francisco, United States, [2]Asian and Pacific Islander Wellness Center, San Francisco, United States, [3]San Francisco Department of Public Health, San Francisco, United States, [4]The Global Forum on MSM & HIV, Oakland, United States, [5]California Institute of Integral Studies, San Francisco, United States, [6]Western University, Epidemiology and Biostatistics, London, Canada*
*Presenting author email: tri.do@ucsf.edu*

**Background:** Bringing an end to the HIV/AIDS epidemic requires engagement of key populations in quality services. Previous research has shown that men who have sex with men (MSM) including transgender MSM and non-transgender (cisgender) MSM who do not feel that their health care providers (HCPs) are sensitive to their needs are less likely to access health services. The nature of such negative experiences with health care providers remains unexplored. We conducted a cross-sectional, global survey of transgender and cisgender MSM. This study sought to explore provider discrimination and its association with service utilization.
**Methods:** The 2014 Global Men's Health and Rights Study was administered to 3857 participants who completed the online survey, available in seven languages. Participants were asked about provider discrimination related to their sexual orientation or gender identity. Respondents were asked the frequency of the following provider experiences within the past 6 months: poor treatment, refusal of treatment, being judged, being reprimanded, and unauthorized disclosure of sexual orientation or gender identity. Responses to these items were averaged to calculate a composite scale on provider discrimination ($\alpha$=0.8698). Multivariable analyses were used to explore the association of discrimination with service utilization within the past 6 months, controlling for demographics and service accessibility.
**Results:** 2,464 MSM completed the survey items of interest, including 97 (3.9%) transgender MSM. Many reported some form of healthcare coverage (86.0%) and having an HCP (70.1%). 16% of the sample had ≥1 experience of discrimination: poor treatment (10%), refusal of treatment (4%), being judged (12%), being reprimanded (7%), and unauthorized disclosure (5%). Provider discrimination was significantly ($p< 0.05$) associated with: STI testing (odds ratio, OR 1.9), having a medical visit (OR 1.6), HIV testing (OR 1.6), and HIV prevention (OR 1.7). Accessing condoms, which does not require provider interaction, was not associated with discrimination.
**Conclusions:** Transgender and cisgender MSM report recent discrimination by their providers when utilizing HIV-related services. Engagement with healthcare providers is associated with a greater number of experiences of discrimination, which may serve as a disincentive for seeking services among MSM. Assessing provider discrimination and training of the healthcare workforce might improve utilization of HIV-related services.

## TUPEE542

### A MULTI-COMPONENT PROGRAM TO MITIGATE THE EFFECTS OF STIGMA AS A BARRIER TO THE UPTAKE OF HIV PREVENTION, TREATMENT, AND CARE SERVICES FOR KEY POPULATIONS IN SENEGAL: HIV PREVENTION 2.0

G. Turpin[1], A. Kane[2], D. Diouf[2], F. Drame[2], K. Coly[1], B. Liestman[1], N. Leye-Diouf[3], H. Diop-Ndiaye[3], C. Toure-Kane[3], D. Castor[4], S. Ketende[1], C. Lyons[1], S. Baral[1]
*[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Enda Sante, Dakar, Senegal, [3]CHU Aristide Le Dantec, Laboratoire Bacteriologie-Virologie, Dakar, Senegal, [4]USAID, Office of HIV/AIDS, Bureau for Global Health, Arlington, United States*
*Presenting author email: gturpin@jhu.edu*

**Background:** Senegal has been successful in the HIV response through an early focus on the scale up of antiviral therapy (ART). However, HIV prevalence has been consistently high among key populations female sex workers (FSW) and men who have sex with men (MSM) suggesting specific barriers in access to HIV prevention and treatment services. The HIV Prevention 2.0 (HP2) is an implementation research study of key populations in Senegal evaluating the utility stigma mitigation as to improve uptake of HIV services. Here, we use the template for intervention description and replication (TIDieR) checklist to describe the implementation of the intervention and lessons learned.
**Description:** The intervention is conducted on three different levels including pre-clinical, clinical, and post-clinical levels or peer-to-peer referral system. A systematic search of existing training materials informed the development of the final modules included which were adapted to the Senegalese context. The pre-clinical community level focused on providing interventions that strengthen individual resilience to stigma through peer facilitators paired with 2 groups of 10 members of the cohort

Tuesday 19 July Poster Exhibition

Wednesday 20 July

Thursday 21 July

Friday 22 July

Late Breaker Posters

Author Index

each. Monthly hour-long group meetings cover 5 modules including HIV prevention, reproductive health, stigma and discrimination, human rights, and living with HIV. The clinical intervention was implemented by facilitators selected according to their profile and professional background, clinical work with KP for the clinical training, and outreach work and experience in BCC for the community intervention to ensure participation and credibility of the trainings to address stigma in health facilities.
**Lessons learned:** Pre-clinical interventions necessitate peers that are very well versed in the various modules and participatory learning methods to ensure fidelity of implementation. In addition, retaining flexibility to allow participants to change groups based on better fit is important. Given the increased stigma towards MSM vs FSW in Senegal, separate clinical trainings were required. In addition, it was important for these to be delivered by Senegalese clinicians limiting the utility of external facilitators.
**Conclusions/Next steps:** Local adaptation and implementation based on stakeholder consultation appears crucial for the success of the trainings. With further prospective measurement, we will be able to assess the utility of these approaches in increasing uptake of ART measured through viral load suppression.

## TUPEE543

### MESSAGING FOR HIV/AIDS PREVENTION AMONG YOUTHS: LEVERAGING THE UBIQUITY OF MOBILE AND SOCIAL MEDIA PLATFORMS THROUGH A MEDICAL CALL CENTRE IN UGANDA

J.M. Bwanika[1,2], D. Musinguzi[1], E. Namirembe[1], W. Lubega[1]
*[1]The Medical Concierge Group Limited, Kampala, Uganda, [2]The Infectious Diseases Institute Limited, Research, Kampala, Uganda*
*Presenting author email: markjbug2@gmail.com*

**Background:** Uganda, with approximately 75% of its population below the age of 35 years, is ranked only second to Niger among countries with a youthful population. At a current adult HIV prevalence of 7.3 %, Uganda continues to bear a heavy burden of HIV. Health programs are constantly faced with the challenge of identifying communication platforms that are relevant to youths. However, social media and mobile messaging platforms have opened up an interconnectivity that makes them an appropriate and futuristic channel for health communication. The Medical Concierge Group provides free HIV and reproductive health consultations with medical doctors through voice calls, SMS, Facebook, twitter and WhatsApp.
**Description:** The Medical Concierge Group Limited (TMCG) set up the call centre to evaluate the value of remote access to medical professionals. Access is through voice calls, a two-way SMS platform, Facebook, Twitter and WhatsApp.TMCG disseminates health information on HIV and related issues as well as provide an avenue for consultations and patient engagement.Through mobile based reminders and retention packages, the platform supports antenatal care ,antiretroviral treatment adherence, circumcision and pharmacovigilance.
**Lessons learned:** TMCG is leveraging existing ubiquitous media.The inbuilt social media and call centre analytics provide frugal mechanisms for real time data summaries and visualizations. In 2015, TMCG had an average of 50,000 monthly users on its platforms. 80% of these were youths below 35 years with a male to female ratio of 60:40. We had 21,000 SMS interactions concerning circumcision, antenatal care and hospital return visits. WhatsApp and Facebook were the most popular messaging platforms with 80 unique interactions on average per day. Most queries centred on condom use, emergency contraceptives and HIV post exposure prophylaxis.
Uptake of the services by men and commercial sex workers was attributed to its confidentiality and privacy. The Call centre also provided a novel channel for community feedback on availability and quality of HIV services.
**Conclusions/Next steps:** Call centres and social media platforms provide affordable, actionable and timely messaging among youths and high risk populations. Patient engagement provides valuable insights for resource allocation and improvement of HIV care.

## TUPEE544

### REACHING UNREACHABLE POPULATION: MULTI-COLLABORATION FRAMEWORK TO IMPROVE YOUNG KEY POPULATION ACCESS TOWARDS HIV-RELATED SERVICES IN DEMONSTRATION SITE OF BANDUNG, INDONESIA

L. Nevendorff[1], Y. Mukaromah[2], A. Nurhalinah[3], S. Perdana[4], D. Widodo[5], I.A. Tasya[6], A. Pedrana[7], B. Parnell[7], S. Leonardi[1], A.E. Budiyani[1]
*[1]UNICEF, Jakarta, Indonesia, [2]National AIDS Commission, Jakarta, Indonesia, [3]National AIDS and STI Control Ministry of Health Republic Indonesia, Jakarta, Indonesia, [4]Fokus Muda (Indonesia Young Key Population Network), Jakarta, Indonesia, [5]Indonesia AIDS Coalition, Jakarta, Indonesia, [6]TB-HIV Research Center, Faculty of Medicine, Padjadjaran University, Bandung, Indonesia, [7]Burnet Instiute, Victoria, Australia*

**Background:** The LOLIPOP Project (Linkages Quality Care for Young Key Population) has been initiated by UNICEF Indonesia in collaboration with Ministry of Health, National AIDS Commission and Young Key Population Network to response emerging HIV prevalence among YKPs in Indonesia. IBBS 2011 data from the Ministry of Health show that they are getting infected with HIV in worrying levels while still adolescents or young adults. Young people in the key populations (YKP) have high rates of infection and are at the center of the epidemic, but have the least access to information and services. In the absence of specific program that are able to increase access for YKPs towards HIV-related services, a model intervention is deemed necessary.
**Description:** In late 2014, a comprehensive participatory need assessments involving local stakeholders have been conducted in Bandung City, as demonstration site. As a result, multi-collaboration framework to target enabling environment, demand creation, supply side and strategic information components have been agreed among national and local partners. The framework is implemented within the existing national strategy of strategic use of ARV with primary goal to increase access to HIV testing, treatment and adherence. Each partner took particular roles according to their primary scope of works.
**Lessons learned:** YKP-friendly training for service providers was implemented to support supply side component. Simultaneously, YKP sensitization workshop was conducted for outreach workers. YKP designated online communication platform and IEC materials have been developed to support education and promotional of the project. Series of coordination meetings were employed to closely monitor the progress. Within six months of project implementation, number of HIV testing among YKPs in Bandung has been increased 66% from baseline data. Similarly, 67% increase is found in number of YKP receiving ART.
**Conclusions/Next steps:** Collaborative approach targeting multi-dimensions of programmatic aspect is deemed effective to boost unreachable population such as YKPs. Similar methods can be utilized to expand the program in wider districts. Particular attention should be given in the near future to accommodate treatment adherence and YKP living with HIV.

## TUPEE545

### CAPTURING ORPHAN AND VULNERABLE CHILDREN'S DATA

R. Mokaya[1], A. Srivastava[2]
*[1]USAID, Nairobi, Kenya, [2]US Agency for International Development, Washington, United States*
*Presenting author email: rmokaya@usaid.gov*

**Background:** Orphans and Vulnerable Children (OVC) affected by HIV became an issue of national concern in 1999 after HIV/AIDS was declared a national disaster by Kenya's President. Kenya adopted the United Nations General Assembly Special Session goals aimed at addressing orphanhood as a priority to address vulnerability faced by children affected by and living with HIV. OVC programs provide a strong platform within communities to effectively identify HIV-infected children and caregivers who do not present to health facilities. They facilitate linkages and referrals to facility and community-based HIV related services through mobilization and result in strengthening of relevant systems and structures.
**Description:** PEPFAR OVC programs focus on implementing core interventions and improving referral networks in priority counties where the HIV prevalence and number of PLHIV and OVC is highest. In FY 14, 711,436 OVC received services in Kenya, 507, 327 (71.3%) of which were ever tested for HIV. Of the OVC who had been tested, 33,738 (7%) were HIV positive and 31,868 (94%) were linked to care and treatment.
To capture accurate data for OVC HTC testing, an OVC Longitudinal Management Information System (OLIMS) was utilized. The OLMIS contributes to HTC by maintaining a longitudinal history of an OVC and caregiver over time while assuring confidentiality through restrictive access and password. The OLMIS captures OVC and caregiver information on data tools and facilitates the use of data for decision making and strategic planning. Innovative functions built into the OLMIS include: validation of data during entry, online transmission of data from local implementers,

and tracking of individual OVC to establish gaps in HIV testing and linkage to care and treatment.
**Lessons learned:** The OLMIS facilitates the provision of targeted support based on the level of vulnerability and facilitates the tracking of services provided, defaulters, and effective referrals.
**Conclusions/Next steps:** The utilization of the OLMIS enables OVC Programs in Kenya to track and follow individual OVC. Tracking individual OVC has helped to identify existing gaps when linking OVC to HTC and to care and treatment. The lists that the OLMIS generates leads to improved and more precise follow-up of HIV-infected children by Community Health Volunteers.

## TUPEE546

### INTEGRATING BRIEF GBV PREVENTION INTERVENTION INTO HARM REDUCTION PROGRAMS FOR WOMEN WHO USE DRUGS IN KYRGYZSTAN: REDUCED VIOLENCE, INCREASED UPTAKE OF HIV SERVICES

O. Rychkova[1], L. Gilbert[2], T. Jiwatram-Negron[2], D. Nikitin[3], T. McCrimmon[2], I. Ermolaeva[4], N. Sharonova[5], T. Hunt[2]
*[1]Open Society Foundations, Public Health Program, New York, United States, [2]Columbia University, Global Health Research Center of Central Asia (GHRCCA), New York, United States, [3]Global Research Institute (GLORI), Bishkek, Kyrgyzstan, [4]Asteria Foundation, Bishkek, Kyrgyzstan, [5]The Podruga Foundation, Osh, Kyrgyzstan*
*Presenting author email: olga.rychkova@opensocietyfoundations.org*

**Background:** The widespread problem of gender-based violence (GBV) among women who use drugs in Central Asia constitutes a serious human rights violation, which is also driving the HIV epidemic in this region. There is an urgent need for brief GBV interventions that can be delivered in low- threshold harm reduction settings in Central Asia and other countries with heroin epidemics.
**Description:** This study evaluated the feasibility and preliminary effects of WINGS, a 2-session evidence-based GBV screening, brief intervention, and referral to treatment (SBIRT) model with HIV testing and counseling (HTC) in identifying and reducing GBV, completing HTC and linking women to GBV and HIV services among women who use drugs in Kyrgyzstan. Using a pre-/post-design, we employed random effects Poisson and Logistic regression analyses for continuous and dichotomous outcomes, respectively.
We screened 109 women who use drugs from two harm reduction sites in Kyrgyzstan, 73 of whom met the criteria, completed a baseline survey and enrolled in the study, and 66 women completed a 3-month post-intervention.
**Lessons learned:** The study identified extremely high rates of GBV among the sample: 73% reported any physical or sexual violence by an intimate partner (IPV) and 60% reported any physical or sexual violence by others (GBV) in the past year. At the 3-month follow-up, participants reported experiencing 59% fewer physical IPV incidents in the prior 90 days than at baseline (p< .001) and 27% fewer physical GBV incidents (p< .01). Participants were more likely to report receiving GBV services (p< .001). The large majority of women (89%) completed HTC. Of these, 4 (7.7%) tested positive for HIV and 3 were linked to HIV care.
**Conclusions/Next steps:** The high rate of participation, significant reductions in GBV and completion of HIV testing from baseline to the 3-month follow up suggest the feasibility and promise of this brief intervention for low-threshold harm reduction settings.

## TUPEE547

### ACTIVE CASE-FINDING IN ORPHANS AND VULNERABLE CHILDREN

R. Mokaya[1], A. Srivastava[2], J. Wanyoike[3]
*[1]USAID, Nairobi, Kenya, [2]US Agency for International Development, Washington, United States, [3]OLMIS TWG, Nairobi, Kenya*

**Background:** OVC affected by HIV became an issue of national concern in 1999 after HIV/AIDS was declared a national disaster by Kenya's President. Kenya has a large population below the age of 18 years estimated at 48 percent and an estimated OVC population of about 2.6 million, nearly half of these are AIDS orphans. OVC programs provide a strong platform within communities to effectively identify HIV-infected children and caregivers who do not present to health facilities. They facilitate linkages and referrals to facility and community-based HIV related services through mobilization, and result in strengthening of relevant systems and structures.
**Description:** PEPFAR OVC programs focus on implementing core interventions and improving referral networks in priority counties where the HIV prevalence and number of PLHIV and OVC is highest. In FY 14, 711,436 OVC received services in Kenya, 507, 327 (71.3%) of which were ever tested for HIV. Of the OVC who had been tested, 33,738 (7%) were HIV positive and 31,868 (94%) were linked to care and treatment. Various strategies to scale-up HTC for OVC were utilized in Kenya, including:

1. Integrating testing within community services,
2. Mobilization and sensitization,
3. Targeted outreach by health facilities with the community,
4. Door-to-door testing
5. same-day HTC for the child and caregiver,
6. Facility-based PITC and,
7. Quarterly tracking of HIV status through the OVC Longitudinal Management Information System.

**Lessons learned:** In order for HTC in OVC programs to be successful, adequate community mobilization and sensitization is vital. To support this, planning with the MoH ensures adequate supply chain management of HIV test kits. Further, training and use of sessional counselors is essential. These workers often already have a heavy workload, so proper training is essential.
**Conclusions/Next steps:** In the Kenya OVC program, testing strategies for OVC resulted in a high positivity rate. OVC platforms can be used to identify children infected with HIV and close the treatment gap between adults and children. Given OVC have risk factors for HIV, programs should seek to implement case-finding strategies that identify HIV-infected OVC in a timely and efficient manner and ensure linkage to care and treatment within health facilities.

# FUNDING FOR PROGRAMMES FOR KEY POPULATIONS

## TUPEE548

### COST ANALYSIS OF VIOLENCE REDUCTION INTERVENTIONS FOR FEMALE SEX WORKERS IN KARNATAKA, INDIA

S. Chandrashekar[1], A. Vassall[2], L. Mohan[3], T. Beattie[4], G. Shetty[3], S. Isaac[5], P. Bhattacharya[5]
*[1]London School of Hygiene and Tropical Medicine, Global Health and Development Department, Bangalore, India, [2]London School of Hygiene and Tropical Medicine, Global Health and Development Department, London, United Kingdom, [3]Karnataka Health Promotion Trust, Bangalore, India, [4]London School of Hygiene and Tropical Medicine, Global Health and Development Department, Bangalore, United Kingdom, [5]University of Manitoba, Centre for Global Public Health, Winnepeg, Canada*
*Presenting author email: sudhashreec@yahoo.co.in*

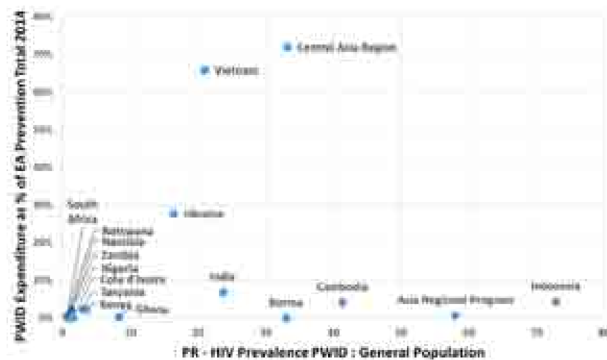
**Background:** The Gates funded, India *Avahan* HIV prevention programme for Female Sex Workers (FSWs) in south India (2003-2013) integrated an 'essential' package of HIV prevention programming with a 'structural' intervention addressing upstream drivers like stigma, violence and discrimination. Epidemiological evidence from Karnataka suggests a significant reduction in HIV/STI infection among FSWs. Polling booth survey data from 15813 FSWs from 16 districts suggests a substantial reduction over time in proportion of FSWs reporting being raped in the past year (30.0% in 2007, 10.0% in 2011, p< 0.001). However the resources needed for such interventions remain unquantified but is necessary for policy makers to estimate how much they need to invest, and what would be the value added. This study assesses the incremental costs of violence reduction interventions for FSWs in Karnataka and provides empirical evidence from real study settings.
**Methods:** We collected intervention financial and programme output data from 16 districts in Karnataka, India for the period 2007-2011 from a provider perspective using an ingredients top-down approach. The activities are carried out at three levels namely policy level advocacy with government officials, secondary stakeholders like police, lawyers and media, and primary stakeholders (female sex workers). All costs are presented in US$ 2011 (3% discount rate).
**Results:** The total costs of violence reduction interventions of 16 districts was $ 216,365 with an average cost of $144,243 ($55,182-$460,058). The costs by subactivity showed that community empowerment activities incurred 46% of the costs followed by legal support (18.4%), advocacy (17.9%) and access to social entitlements (17.6%). The number of reported incidents of rights violation against FSWs over 4 years was 14,208 of which 14% were committed by police. The unit cost for reaching the estimated FSW population (187,675) with these interventions over the years was $11 (2-34) across the districts.
**Conclusions:** We recommend that addressing violence and vulnerability among FSWs should form integral part of HIV prevention interventions Such efforts are relatively inexpensive and can have substantial impact in terms of supporting prevention efforts and reducing harm. Interventions should be strengthened and sustained through specific allocation of resources.

## TUPEE549

### MATCHING PEPFAR FUNDED HIV PREVENTION ACTIVITIES AND SPENDING FOR PEOPLE WHO INJECT DRUGS WITH EVIDENCE: OPPORTUNITIES TO INCREASE ALIGNMENT

C. Chandra, J. Sherwood, B. Honermann, L. Lazar, J. MacAllister, S. Blumenthal, K. Lindsey, G. Millett
*amfAR, The Foundation for AIDS Research, Washington, United States*
*Presenting author email: christina.l.chandra@gmail.com*

**Background:** People who inject drugs (PWID) constitute a disproportionate burden of the HIV epidemic, accounting for nearly 1/3 of new HIV infections outside of sub-Saharan Africa. PEPFAR has funded prevention programs targeting PWID since its inception, and established the IDUP budget code in 2009 to track allocations. We exclusively analyzed Country Operational Plans' (COPs) IDUP funding from 2009-2015 and Expenditure Analyses (EAs) for PWID in 2013-2014.
**Methods:** Using amfAR's COPs Database, planned funding under IDUP was analyzed for COP2009-2015 and compared to PWID-specific spending in EAs 2013-2014. Use of mechanism narratives post-2013 have been discontinued, so COP2013 IDUP narratives (n=71) were reviewed and coded for activities outlined in COP2013 and WHO technical guidance for PWID. HIV prevalence ratios (PRs) comparing PWID to the general population were calculated for countries and regions with available data (n=17) and plotted against 2014 PWID expenditure as a percent of total prevention spending.
**Results:** Overall IDUP funding steadily decreased from COP2013-2015 despite median country allocations for IDUP increasing during this period. The most frequent PEPFAR-funded activity for PWID was technical assistance and capacity building (14%) - equally least frequent were needle and syringe programs (NSPs) and policy reform around PWID (3% respectively). PWID-specific spending in 2014 amounted to less than 10% of prevention expenditure in 14 (82%) countries, 5 (36%) of which had PRs greater than 20.



*[Figure. HIV Prevalence Ratio of PWID to General Population Compared to 2014 Expenditure by PEPFAR]*

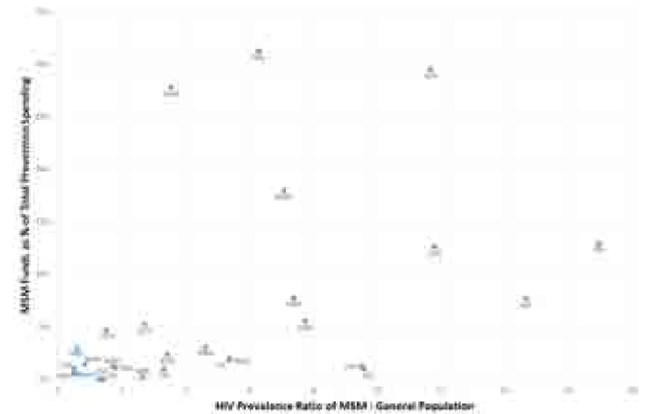
**Conclusions:** Strong resource allocation for PWID is a critical HIV prevention opportunity, especially where HIV prevalence among PWID is high. To adequately plan IDUP funding, investments in data collection and adherence to international guidelines are necessary. Evidence-based prevention activities in the WHO guidance should be considered funding priorities; including NSPs. US government restrictions on NSP support are problematic, particularly when domestic restrictions have been lifted. Moreover, mechanism narratives help to identify funded PWID activities. Without indication of these activities, transparency is diminished.

## TUPEE550

### CHALLENGES AMID INCREASES IN PEPFAR COP INVESTMENTS FOR MSM AND TRANSGENDER INDIVIDUALS, 2013-2015

J. MacAllister, L. Lazar, J. Sherwood, B. Honermann, C. Chandra, K. Lindsey, S. Blumenthal, G. Millett
*amfAR, The Foundation for AIDS Research, Public Policy Office, Washington, United States*
*Presenting author email: jack.macallister@amfar.org*

**Background:** Men who have sex with men (MSM) and transgender individuals (TG) are at greater risk of HIV acquisition than general adult populations worldwide. We tracked MSM/TG funding in 2013 PEPFAR Country Operational Plans (COP) and MSM/TG 2014 expenditures using the MSM/TG cross-cutting budget category.
**Methods:** Using amfAR's PEPFAR COP Database, funding data for countries utilizing the MSM/TG cross-cutting budget category in COPs 2013-2015 (n=32) were analyzed for changes over time. Planned spending and expenditure data for MSM/TG were each tabulated as raw totals, and percent of planned or observed expenditures in each country. COP mechanism narratives were reviewed and coded for MSM/TG-specific activities. HIV prevalence ratios (PRs) comparing MSM to the general population were calculated and plotted against 2014 MSM/TG expenditures as a percent of total prevention spending.
**Results:** From 2014-2015, total planned funding for MSM/TG across countries increased by 79%. 59% (19/32) of countries increased abosulte funding, while 34% (11/32) of countries decreased funding and 38% (12/32) decreased MSM/TG funds as a proportion of total funding. Of the 2013 COP mechanism narratives containing MSM/TG cross-cutting funds, 44% focued on key populations (KP) generally, 22% (22/73) omitted MSM, TG or KPs, 4% (3/73) were specific to MSM, and 1% (1/73) were specific to TG. Of 28 countries with MSM HIV prevalence data (n=28), 7 had PRs in the top quartile (PR >7.7); yet 57% (4/7) spent below the mean (8.24%) on MSM as a percent of total prevention spending.
**Conclusions:** The majority of countries increased their investments in MSM/TG from 2013-2015, but a substantial number decreased or eliminated such funding altogether. Moreover, the COP mechanism narratives did not universally provide information on the precise nature of PEPFAR's investments for MSM and even fewer for TG. A number of countries with high HIV prevalence among MSM spent disproportionately less on this population.



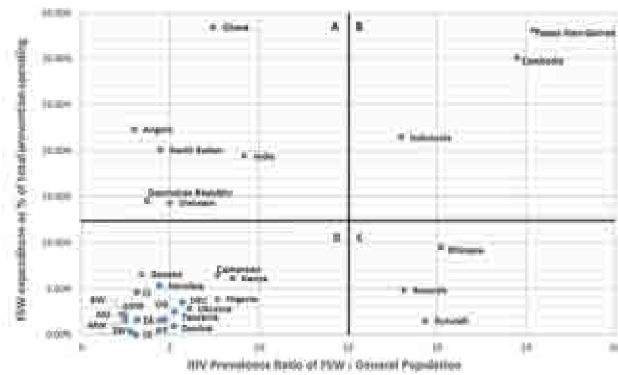
*[Figure. HIV Prevalance Ratio of MSM to General Population Compared to 2014 Expenditures]*

## TUPEE551

### DOES FUNDING MATCH THE BURDEN? TRACKING PEPFAR EXPENDITURES IN HIV PROGRAMMING FOR FEMALE SEX WORKERS FROM 2013 TO 2015

J. Sherwood, L. Lazar, B. Honermann, J. MacAllister, S. Blumenthal, K. Lindsey, G. Millett
*amfAR, The Foundation for AIDS Research, Washington DC, United States*
*Presenting author email: jennifer.sherwood@amfar.org*

**Background:** Globally, female sex workers (FSW) are disproportionately affected by HIV. PEPFAR has been a critical funder of FSW HIV programs, and in 2013 added criteria to country operational plans (COPs) to track FSW funding. We analyze FSW funding from 2013-2015 COPs and 2014 Expenditure Analyses (EAs) to describe planned and spent FSW funds.
**Methods:** Funding data for countries utilizing the FSW cross-cutting category in 2013-2015 COPs (n=35), sourced from amfAR's COPs database, were analyzed for changes over time. Individual mechanisms were coded for FSW-specific activities by budget code and focus area frequency. HIV prevalence ratios (PRs) comparing FSW to the general population were calculated for countries with available data (n=31) and plotted against 2014 FSW expenditures as a percent of total prevention spending. The resulting plot was divided into quadrants: higher spending/lower PR (A); higher spending/higher PR (B); lower spending/higher PR (C); lower spending/lower PR (D).
**Results:** From 2013-2015, planned FSW funding increased in total dollars and as a proportion of total funding. Six (17%) countries decreased planned FSW funds by 100% in COP 2015 and 14 (41%) countries spent a lower percentage of total funding in 2014 for FSW than planned in 2013. Nineteen (61%) countries were classified D, 6 (19%) as A, and 3 (10%) as each B and C. Review of 2013 mechanism narratives showed that 81% (78/96) described FSW activities, while 18% (17/96) included FSW funds without mentioning FSW.



[Figure 1. HIV Prevalence Ratio of FSW to General Population Compared to 2014 Expenditure by PEPFAR]

**Conclusions:** Disproportionate HIV risk necessitates FSW's prioritization in resource allocation. PEPFAR COP funding for FSW has increased in recent years, however, there is extreme country variability. Bolstering funding commitments for FSW in settings with wide disparity in HIV risk for FSW is epidemiologically sound and vital to the HIV response. Stakeholder involvement in application of FSW cross-cutting funds is imperative and can be assisted by more explicit descriptions of activities.

## TUPEE552

### KEY POPULATIONS-LED INTERVENTIONS IN MALAWI, TANZANIA AND BOTSWANA TO REALISE MEANINGFUL AND INCLUSIVE GLOBAL FUND INVESTMENT

K.L. Mabote
*AIDS and Rights Alliance for Southern Africa, Advocacy, Cape Town, South Africa*

**Background:** The AIDS and Rights Alliance for Southern Africa's (ARASA) 2014 informal assessment on meaningful engagement of key populations (KPs) in Global Fund processes in a few SADC countries showed that KPs require capacity strengthening on linkages between human rights and HIV, as well as Global Fund processes. They required opportunities to influence strategic investment of Global Fund and other resources. Technical and financial support could facilitate the creation of platforms that would enable consistently engage on content, share materials and information as well as streamline consultations with their constituencies for feedback on an on-going basis. KPs were eager to engage more effectively with members of the Country Coordinating Mechanism (CCM) as well as be considered principal and sub-recipients of current and future grants.
**Description:** From March 2015 to January 2016, ARASA in collaboration with the International Treatment Preparedness Coalition (ITPC) worked with Key populations groups (namely sex workers, people who use drugs and LGBTI) in Tanzania, Botswana and Malawi to undertake interventions that were aimed at increasing Global Fund investments in interventions that would improve the health and rights of these inadequately services populations. Through focused interventions including budget monitoring training, focused trainings with their constituencies as well as with influencers such as health care workers and religious leaders, 'days of action' focusing on financing for health, and co-ordinated interventions geared towards attaining them seats on the CCMs, these partners were able to increase their constituencies' visibility in their respective countries' Global fund processes.
**Lessons learned:** In two countries, KPs were able to secure seats on their CCMs; in two countries - national allocations to key populations budgets were increased by the national AIDS Councils and in one country, a formalised sex work alliance was established.
**Conclusions/Next steps:** As a result of the success of the interventions, more funding has been secured to continue this work and to bolster sustainability of their interventions. This funding will now focus on documenting these and other experiences; to allow for better modelling of interventions for KPs in other countries.

# INTEGRATION OF HIV AND SEXUAL AND REPRODUCTIVE HEALTH FOR KEY POPULATIONS

## TUPEE553

### ACCESS TO HIV SERVICES FOR NIGERIA'S INTERNALLY DISPLACED PERSONS: THE NEED FOR INCLUSION

O. Omole[1], O. Falope[2], T. Folaranmi[3], B. Adenuga[1]
*[1]Howard University Hospital, Dept of Community and Family Medicine, Washington DC, United States, [2]University of South Florida, College of Public Health, Tampa, United States, [3]Stream Insight Inc, Lagos, Nigeria*

**Background:** Nearly 3.3 million Nigerians live as refuges in Internally Displaced Peoples (IDPs) camps within Nigeria and in the adjoining countries . Nearly all these individuals were forced to leave their homes amidst the Boko Haram insurgency. With an HIV prevalence rate of 3.2% among 15- to 49-year-old, the response of the Nigerian government to the health needs of these displaced individuals with particular reference to HIV/AIDS has been underwhelming. There is a strong relationship between conflict and HIV/AIDS spread. The IDPs are particularly susceptible because of sexual violence & exploitation, lack of access to reproductive health services, and lack of health infrastructure. There is also the risk of further spreading HIV to the host communities.
**Description:** A media review using newspapers and the internal displacement monitoring center (IDMC) was done to identify the history of IDPs, their locations, main health issues. A literature review was done and informal interviews were carried out to identify the challenges of providing HIV/AIDS care services in such settings.
**Lessons learned:** Many IDP camps in Nigeria do not provide HIV counseling and testing to identify new cases, HIV/AIDS awareness campaigns, or ARV refills for patients already on medications. Newly diagnosed HIV patients are not integrated into the health system. Reasons for these include
1) No coherent policy on HIV/AIDS in camps
2) Lack of funds
3) Non availability of PEPFAR drugs in the camps
4) Non integration of IDP camps with nearby primary health centers.
**Conclusions/Next steps:** The chaos and instability in IDP camps has created numerous challenges of access to care for HIV/AIDS. The federal and state governments must integrate and coordinate with NGOs and international organizations working with IDPS to provide comprehensive HIV/AIDS care services urgently. There is also a need to track HIV/AIDS incidence and prevalence in camps and create long term HIV/AIDS strategies that work beyond the current instability. Nigeria must invest in critical public health infrastructure.

## TUPEE554

### SEXUAL HEALTH NEEDS OF WOMEN WHO INJECT DRUGS IN KENYA: IMPLICATIONS FOR HIV AND SRH PROGRAMMES

J. Ndimbii[1], M. Kalama[1], S. Ayon[1], C. Kihara[2], D. Bajpai[2], S. McLean[2], G. Mburu[2,3]
*[1]Kenya AIDS NGOs Consortium (KANCO), Programs, Nairobi, Kenya, [2]International HIV/AIDS Alliance, Brighton, United Kingdom, [3]Lancaster University, Lancaster, United Kingdom*
*Presenting author email: jndimbii@kanco.org*

**Background:** HIV prevalence among women who inject drugs in Kenya is high at 44.5% (NASCOP 2012). Harm reduction interventions targeting people who inject drugs are generally focused on injecting practices, and often gender blind. Sexual and reproductive health (SRH) needs and rights of people who inject drugs, particularly women who use drugs, are poorly understood and addressed. To remedy this, this study explored sexual and reproductive health needs of women of reproductive age who inject/use drugs in Coastal Kenya, to inform the development of community-based and outreach-based integrated SRHR and harm reduction services.
**Methods:** Semi structured interviews (n=24), and focus group discussions (4 sessions, n= 28) were conducted with women of reproductive age who use drugs in Mombasa and Kilifi, Kenya. The mean age of the participants was 29, age range was 19 - 56; and mean duration of injecting was 2.8 years and using drugs was 8.5 years. Interviews and focus group discussions explored contraceptive use and access, pregnancy and termination, parenthood, sexual practices and awareness and experience of sexually transmitted infections and intimate partner violence. Data were analyzed using NVIVO software to identify and codify key themes.
**Results:** Out of 52, 99% had ever tested for HIV, 5 were not willing to disclose their status, 1 had not tested and 13 were HIV positive. Nine of the respondents reported at least one unintended pregnancy. Respondents reported going for ante-natal care (ANC) either late or at the time of delivery. Barriers to ANC and PMTCT services reported were: costs, service provider attitudes and the lack of time. Some of the participants had delivered outside of a health facility. The rates of follow up on im-

munization and child health were poor. Respondents reported attempting termination of pregnancy through deliberate heroin overdose and other unsafe methods. Integration of services was acceptable to the respondents. Respondents also reported intimate partner violence and coercive sexual practices.
**Conclusions:** There are high unmet SRH&R needs among women who use drugs in Kenya. Integrating comprehensive SRH&R, including ANC and PMCTC services, with harm reduction interventions is required to advance rights to health for women who use drugs in Kenya.

## TUPEE555

### DELIVERING INTEGRATED HIV/MODERN FAMILY PLANNING SERVICES TO FEMALE SEX WORKERS THROUGH MOBILE, COMMUNITY-BASED, INTEGRATED BIOMEDICAL SERVICES IN FIVE REGIONS OF TANZANIA

C. Casalini[1], J. Basomingera[2], T. Lennemann[1], D. Boyee[1], A. Komba[1], J. Schueller[3], H. Mahler[1]
*[1]Jhpiego, Program, Dar es Salaam, Tanzania, United Republic of, [2]Engenderhealth, Dar es Salaam, Tanzania, United Republic of, [3]USAID, Dar es Salaam, Tanzania, United Republic of*
*Presenting author email: caterina.casalini@jhpiego.org*

**Background:** Unplanned pregnancies are an occupational hazard for female sex workers (FSW) who infrequently access the health system due to fear of stigma and discrimination and the criminalization of sex work. Key population-friendly mobile community-based HIV testing and counseling “plus” (CBHTC+) teams operated by the PEPFAR-funded Sauti Program provide family planning (FP) counseling and services integrated with HIV testing and counseling, and STI, TB, gender-based violence, and alcohol and drug screening in hotspots in five regions of Tanzania. This abstract describes the uptake of FP services by FSW in this program.
**Description:** Patient level data was collected during CBHTC+ services, entered into a central database through single data entry, cleaned and analyzed using STATA statistical software. Chi2 test compared proportions and logistic regression assessed associations.
**Lessons learned:** Between August and December 2015, records were entered for 9,332 females reached through the Sauti program, of which 30% (n= 2,712) identified as FSW (median 28 years [IQR 24-33]). More than one third (36%, n=967) of this population had had previous experience with contraception, mainly using injectables (52% n=503) followed by implants (22%, n=217) and oral contraceptives (17%, n=165). Two percent (n=22) had used an intrauterine device before, and 1% (n=13) reported tubal ligation. At the time they accessed Sauti services, only 22% (n=592) were currently using FP, with a similar distribution of methods. Following their visit to Sauti, 13% (n=357) newly initiated FP, preferring implants (17%, n= 86) over injectables (15%, n=74) and pills (7%, n=34) besides male condoms (52%, n=257). Younger age and previous experience with FP was associated with FP uptake (OR 0.98, p= 0.011: OR 2.3, p< 0.001 respectively).
**Conclusions/Next steps:** FSW, especially younger FSW, have an unmet need for modern FP methods which can be addressed through easily accessible and non-judgmental FP services. Injectables were the most common FP method in the population, but when choosing in the KP-friendly supportive counseling environment of the Sauti Program, next to male condoms, FSW chose implants over injectables; suggesting a subgroup of FSW who have existing interest in long term FP. Programs learn more about the fertility intentions of FSW to help further shape the FP counselling.

## TUPEE556

### EXPANDING THE CONTRACEPTIVE METHOD MIX FOR WOMEN AT HIGH-RISK OF HIV: EXPERIENCES FROM THE CAPRISA 008 TENOFOVIR GEL IMPLEMENTATION TRIAL

C. Baxter[1], L. Mansoor[1], K. Mngadi[1], N. Ngcobo[1], N. Yende-Zuma[1], T. Gengiah[1], Q. Abdool Karim[1,2], S. Abdool Karim[1,2]
*[1]Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, [2]Columbia University, Epidemiology, New York, United States*
*Presenting author email: cheryl.baxter@caprisa.org*

**Background:** For safety reasons, women participating in microbicide trials are required to be on a non-barrier contraceptive. The predominant contraceptive choice in South Africa is an injectable hormonal contraceptive that is administered 2 or 3-monthly. Data from observational studies suggest that injectable hormonal contraceptive use, particularly depot medroxyprogesterone acetate (DMPA), may be associated with increased HIV risk. Expanding the contraceptive choices for women, especially those living in high HIV burden countries, is therefore important.
**Methods:** Women participating in the CAPRISA 008 Tenofovir Gel Implementation trial were offered a range of contraceptives including injectables (DMPA or Nur-Isterate), oral contraceptives (OC), intrauterine contraceptive device (IUCD), and female sterilization (tubal ligation). Contraceptive implants were also introduced as an additional contraceptive option part way through the study. Women were counseled on all the contraceptive methods and their choices were captured on a log that was reviewed at each subsequent study visit in order to provide more contraceptive options, assess adherence to the method of their choice and to record any switches in contraceptive use. Pregnancy was assessed at each study visit. Descriptive analysis of contraceptive data was undertaken.
**Results:** A total of 372 women were eligibly enrolled in CAPRISA 008. At enrolment, 278 (74.7%) of these women were on injectables, 75 (20.2%) were taking OC, 16 (4.3%) were sterilized, 1 (0.3%) had a contraceptive implant and 2 (0.5%) had undergone a hysterectomy. By the end of the study, the number of women on injectables and OCs had declined to 177 (47.6%) and 63 (16.9%) respectively, while the number choosing contraceptive implants or IUCDs had increased to 81 (21.8%) and 6 (1.6%) respectively, and 27 (7.3%) women were not on any form of contraception. In total, 70 (23.3%) women who were using an injectable contraceptive at enrolment switched to the contraceptive implant during study follow-up.
**Conclusions:** Structured contraceptive counselling to promote a wide range of contraceptive choices resulted in an expanded contraceptive method mix in a population that has predominantly favoured injectable contraceptives. If the relationship between DMPA and HIV risk is confirmed then it is reassuring to know that women are willing to switch to alternate contraceptive methods.

## TUPEE557

### BEING A CHILD, A WIFE AND A WIDOW: PROTECTING GIRLS AGAINST EARLY AND FORCED MARRIAGES

F.P. Hadebe-Dlamini
*Bhekuzulu Self Sufficient Project, NGO, Estcourt, South Africa*
*Presenting author email: fezile.bsspcares@hotmail.co.za*

**Background:** *Ukuthwala*, a once romanticised cultural practice, whereby a girl and boy in love arranged for the girl to be ‘abducted’ to compel parents’ consent for marriage, is now being distorted (UNFPA 2013) with devastating results. Young girls in impoverished communities are forced to marry older men, often trading bride-price for their right to education. Multiple-concurrent partnerships and polygamy are prevalent, placing girls at greater risk of HIV infection. *Ukuthwala* is directly contributing to low levels of education and employment, increased poverty and poor health outcomes for girls and their families. Keeping girls at school reduces HIV incidence and improves employability and health outcomes (UNICEF 2009). A community intervention in South Africa, is engaging girls, parents and leaders to end early and forced marriage.
**Description:** Bhekuzulu Self Suffient Project (BSSP) is an organisation dedicated to eradicating harmful practices and promoting the health and well-being of young girls. BSSP is targeting Grade 8-12 learners, and the broader community, in the Loskop area of KwaZulu-Natal, with a programme to sensitise them about the negative impacts of forced and early marriage, to help reduce poverty and mitigate the impact of HIV and AIDS.
**Lessons learned:** BSSP conducts Community Dialogues, awareness campaigns, workshops, health education and talk shows. Over the past three years, it has referred young brides to psychological support for counselling and to the local clinic for HIV-testing and family planning. It has supported them to share their views against *Ukuthwala*.
BSSP has developed good working relationships with the mobile clinic and the district hospital. It has formed partnerships with the Department of Education, Legal Aid and local schools.
Patriarchy remains entrenched and despite progress, BSSP faces challenges with some chiefs who regard interventions in their villages as a threat to tradition. Legal action is not taken in statutory rape cases and young people affected find that elders still hold the power and are supported by local men and traditional authorities.
**Conclusions/Next steps:** BSSP’s programme shows that harmful practices can be effectively challenged. Steps to strengthen the interventions include advocacy for a permanent local clinic and legal aid facility.

## TUPEE558

### *SHADOWS AND LIGHT:* ADDRESSING THE LINKED SEXUAL AND REPRODUCTIVE HEALTH (SRH) AND HIV NEEDS OF KEY POPULATIONS

D. McCartney[1], H. Parry[2], D. Bakomeza[3], N. Jagdish[4], L. Kayaro[5], A. Tena[6], A. Metzner[7]
*[1]International Planned Parenthood Federation (IPPF), London, United Kingdom, [2]Independent Consultant, Hove, United Kingdom, [3]Reproductive Health Uganda, Kampala, Uganda, [4]Family Planning Association of India, Mumbai, India, [5]Family Health Options Kenya, Nairobi, Kenya, [6]Cameroon National Association for Family Welfare, Yaoundé, Cameroon, [7]GIZ, German BACKUP Initiative, Eschborn, Germany*
*Presenting author email: dmccartney@ippf.org*

**Background:** *Shadows and Light* was a three-year project that was implemented by four IPPF Member Associations (MAs) between October 2012 and September 2015, funded by the German BACKUP Initiative. The project increased service providers' ability to address the linked SRH and HIV needs of four key populations at increased risk of HIV: transgender people; sex workers; people who use drugs; and men who have sex with men. The project focused on building local capacity of key populations to engage in Global Fund processes as these mechanisms offered key opportunities to influence, deliver and sustain services to key populations.
**Description:** An independent review was conducted during the final month of implementation (September 2015) to document the key lessons learned. The methodology involved review of project documentation and interviews with 13 key stakeholders. The report synthesised the overarching achievements of the project across the four countries; highlighted the main challenges and obstacles faced; identified key lessons learned; and suggested recommendations.
**Lessons learned:** The project achieved significant impact in each of the four MAs in terms of capacity to deliver SRH and HIV services for key populations. Key achievements included reach to young key populations and focus on gender-related issues; involving key populations as agents of change; reducing community-level stigma and discrimination; working through established community structures; and building partnerships to strengthen referral mechanisms. Table 1 outlines the key lessons learned under three thematic areas
(1) planning and design of integrated services for key populations;
(2) increasing key population involvement and building leadership; and
(3) advocating for and funding integrated services for key populations.

| Planning and designing integrated services | Increasing involvement of key populations | Advocating and funding for key populations |
|---|---|---|
| Effective interventions must recognise and respond to the complex and often overlapping vulnerabilities of key populations, and include broader and related health and SRH issues | Promoting meaningful involvement and leadership at all stages of project increases the effectiveness of programmes as well as reducing stigma | Using restricted project resources strategically to complement gaps in existing programmes demonstrates impact and advocacy can ensure approaches scaled up |
| Identifying appropriate and innovative ‚entry points' is critical to engage key populations on SRH issues | Engagement with wider key population networks was limited in practice and there is scope to engage further with these networks as strategic partners | Small pilot projects can demonstrate important lessons regarding the benefits of integration for key populations, from which larger programmes can develop |
| When services are genuinely stigma-free, preference is to access services at regular times rather than having a designated ‚key populations' clinic' | Genuine leadership development of key populations takes time and requires strategic investment | Flexibility on the part of donors can enable projects to respond more quickly and effectively to specific needs as they arise |
| Key populations prefer being able to access services through a ‚one stop' centre, particularly in hostile environments | Continued advocacy is required at national level to increase key population representation on CCMs | There is an urgent need to prioritise investment in tailored and targeted services for young key populations |

*[Table 1: Lessons learned and recommendations for addressing the linked SRH and HIV needs of key populations]*

**Conclusions/Next steps:** *Shadows and Light* has demonstrated that IPPF's strong rights-based approach is a solid foundation on which to build upon their existing work with vulnerable and socially excluded groups to provide integrated SRH and HIV services for key populations, offering tremendous potential to scale up this approach and the integration of services for key populations through IPPF's established global infrastructure.

## TUPEE559

### UNDERSTANDING FACTORS RELATED TO PATIENT-PROVIDER COMMUNICATION ABOUT PREGNANCY AND HIV AMONG FEMALE SEX WORKERS LIVING WITH HIV IN SANTO DOMINGO, DOMINICAN REPUBLIC

D. Cernigliaro[1,2], C. Barrington[3], M. Perez[4], Y. Donastorg[4], D. Kerrigan[1]
*[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]New York University- Lutheran, New York, United States, [3]University of North Carolina, Gillings School of Global Public Health, Chapel Hill, United States, [4]HIV Vaccine Research Unit. Instituto Dermatalógico y Cirugia de Piel Dr. Humberto Bogart Diaz, Santo Domingo, Dominican Republic*
*Presenting author email: danacern@gmail.com*

**Background:** Female sex workers (FSW) living with HIV are a vulnerable population for multiple health concerns, yet are understudied in the public health literature. FSW face barriers to care as well as increased risk for sexual and reproductive health complications among other health issues, therefore communication with health providers can play an important role before and during pregnancy.
**Methods:** Data was analyzed using bivariate and multivariate logistic regression from a cohort of 253 FSW living with HIV who were of reproductive age while living with HIV in Santo Domingo, Dominican Republic to assess factors associated with ever having communicated about pregnancy with a health provider.
**Results:** Almost all women had been pregnant (95.65%; mean: 4.5 pregnancies), many had been pregnant after HIV diagnosis (36%; mean: 1.6) and reported wanting more children (28%; mean: 1.6 children). Over half (58%; n=146) reported having ever spoken to any health provider about pregnancy among women living with HIV. Of those, about 38% (56/146) had been pregnant since diagnosis and 24% (36/146) indicated wanting more children. Of participants who have been pregnant after HIV diagnosis (n=91), about 38% (35/91) never discussed pregnancy with a health provider and about 48% (34/91) indicated a desire for more children. Of the total population, about 56% (142/253) do not feel that if an HIV positive woman wants to get pregnant she should, however about 75% (191/253) felt that health providers are supportive of pregnancy in women living with HIV. Multivariate logistic regression found significant associations between having spoken to a health provider about HIV in pregnancy and a more positive perception of their health provider (AOR: 1.97; 95% CI: 1.01, 2.48) and years since HIV diagnosis (AOR: 1.07; 95% CI: 1.00, 1.13). Negative associations were seen with history of drug use (AOR: 0.38; 95% CI: 0.20, 0.90) and current alcohol use (AOR: 0.52; 95% CI: 0.30, 0.92).
**Conclusions:** This study examines missed opportunities and barriers in patient-provider communication about pregnancy for FSW living with HIV. Findings highlight the importance for integrated, non-judgmental and tailored care and communication surrounding pregnancy, addressing the multiple risk factors for this highly vulnerable population.

## TUPEE560

### PROMOTING SRH SERVICES TO IMPROVE HIV PREVENTION FOR YOUNG FEMALE SEX WORKERS: EXPERIENCE FROM THE ABHAYA PROGRAMME IN INDIA

V. Arumugam, N. Mazumder, S. Mehta, J. Robertson
*India HIV/AIDS Alliance, New Delhi, India*
*Presenting author email: aviswanathan@allianceindia.org*

**Background:** Young female sex workers (FSW < 24 years old) are marginalised, and often difficult to reach with HIV-related services. It has also been observed that women who have been in sex work have various sexual health issues that are undiagnosed and therefore untreated.
**Description:** India HIV/AIDS Alliance implements the Abhaya programme in Gujarat, Delhi and Telangana to provide sexual reproductive health (SRH) services to FSW. It also explores SRH as a starting point for HIV-related service delivery. Young FSW, below 24 years of age, were reached through health camps, hotspot meetings and drop-in-centres by outreach workers, in coordination with the government-funded Targeted Intervention (TI) projects. The project provided SRH education, counselling/referral and service linkages with family planning clinics, gynecologists and STI clinics. Clients were also motivated to seek and/or referred for HIV services, i.e. HIV testing and ART.
**Lessons learned:** 1,074 young FSWs (≤ 24 years old) were educated on SRH and HIV-related services. They were mainly counselled on oral birth control (n=348), menstruation hygiene management (n=409) and cervical cancer (n=88). The most commonly availed services from the project were oral birth control (n=181), mensuration issues (n=198), emergency contraception pills (n= 58) and cervical cancer Pap smear testing (n=26). Reaching out to FSW with SRH services resulted in an increased uptake of HIV prevention services. 14 FSWs were diagnosed as HIV+ and were linked with ART centres.
**Conclusions/Next steps:** Reaching out to the young FSWs via an SRH approach was successful as it created an enabling environment for SRH discussions in a population

still grappling with the challenges of adulthood and sexuality and managing these factors in the context of sex work. These discussions have led to increased HIV counselling, testing and linkages with care, support and treatment services.

## TUPEE561

### BRINGING SEXY BACK: PREP AND SEXUAL HEALTH SERVICES FOR YOUNG URBAN MEN WHO HAVE SEX WITH MEN

I. Udoh[1], J. Myers[2], R. Frazier[2], K. Koester[2], J. Horwitz[3], M.-S. Kang Dufour[2], M. D'Arata[3], K. Kennedy[3], B. Packard[2], X. Erguera[2], R.M. Grant[4], J.H. Burack[3]
*[1]Pangaea Global AIDS, Oakland, United States, [2]University of California, San Francisco, Center for AIDS Prevention Studies, San Francisco, United States, [3]Alta Bates Summit Health Center, East Bay AIDS Center, Oakland, United States, [4]University of California, San Francisco, Gladstone Institutes, San Francisco, United States*
*Presenting author email: horwitj@sutterhealth.org*

**Background:** The CDC estimates that young men who have sex with men (Y/MSM) account for nearly 75% of all new infections among youth in the United States. Improving access to culturally and clinically relevant sexual health services is critical for stemming the tide of new infections, particularly in urban settings such as Oakland, California, where a HIV State of Emergency has existed since 1998. The Connecting Resources for Urban Sexual Health (CRUSH) Project was conceived as a comprehensive approach to HIV prevention where Y/MSM, regardless of serostatus, can access affirming and innovative sexual health services.
**Description:** The aim of CRUSH is to implement and evaluate the effectiveness of a package of HIV care, treatment and prevention, including routine sexual health services: STI screening and treatment, PrEP and PEP access, for Y/MSM of color. Utilizing a broad range of scientific and community partners, patients can arrive for scheduled or drop-in visits; receive regular HIV testing, be assessed and treated for STIs, access PrEP and PEP, and adherence support for PrEP and ART. To engage Y/MSM, CRUSH embodies a "clinic without walls" structure, supporting retention efforts, allowing youth to access barrier free services.
**Lessons learned:** Since February 2014, CRUSH enrolled a total of 262 HIV negative and 81 HIV positive participants to receive sexual health care; 238 have received PrEP. About 15.5% (n=37 of 238) of those receiving PrEP were assessed as needing PEP at some point in the course of the study. Nearly 29% (n=99 of 343) are Y/MSM of color. Average age of all participants is 24.6. Average amount of time participants stay on PrEP is 36 weeks of a 48 week study period.
**Conclusions/Next steps:** Uptake of sexual health services in this setting for Y/MSM of color was higher than anticipated. Providing routine STI treatment is a critical for integrating PrEP into an existing HIV primary care setting. Ensuring flexible clinic access including drop in visits for STI testing and treatment for both HIV positive and negative youth is essential to engage Y/MSM in routine sexual health. Intensified in-reach and outreach and messaging targeting Y/MSM of color are needed for engagement into PrEP.

## PREVENTION AND TREATMENT PROGRAMMES FOR AND WITH ADOLESCENTS AND YOUNG PEOPLE, INCLUDING THOSE FROM KEY POPULATIONS

## TUPEE562

### AN INNOVATIVE COMBINATION STRATEGY TO ENHANCE HIV TESTING AMONGST ADOLESCENTS IN SOUTH AFRICA

G. Fatti, N. Manjezi, N. Shaikh, E. Mothibi, O. Oyebanji, A. Grimwood
*Kheth'Impilo, Cape Town, South Africa*
*Presenting author email: geoffrey.fatti@khethimpilo.org*

**Background:** Adolescents form a large proportion of the HIV burden in sub-Saharan Africa, contributing to approximately 30% of all new infections. However, low levels of HIV testing and counselling (HTC) access and uptake amongst adolescents frequently results in late HIV diagnosis and their late entry into treatment programs. We report on an innovative combination approach to enhancing HIV diagnosis amongst adolescents in very high HIV prevalence settings in South Africa.
**Methods:** A cross-sectional study utilizing routine individual-level HIV testing data of adolescents (aged 10-19 years) tested as part of a program using a combination of HIV testing strategies in two districts having antenatal HIV prevalences of 39%-41% was performed between January 2014 and October 2015. Testing strategies involved:
I) Home-based HIV testing of consenting household members of known HIV-positive clients identified at primary healthcare centres (index client trailing);
II) Home-based testing of household members in households in the surrounding areas of index case households (door-to-door testing); and
III) HIV testing at special outdoor events (campaign testing).
**Results:** Amongst 4800 adolescents who received counselling, 4756 (99.1%) consented to HIV testing. The median age of tested adolescents was 17.6 years (IQR: 15.3-18.9 years) and 36.3% were male. The proportions who received testing for the first time were 90% amongst males and 85.7% amongst females (P< 0.0001). 2558 (54%) adolescents were tested in index client households, 1882 (40%) during door-to-door testing, and 292 (6%) were tested at campaigns. Overall, 7.5% of females and 3.9% males tested HIV positive (P< 0.0001). Amongst those who tested positive, 66.7% were late adolescent girls (aged 16-19 years). HIV positivity was higher at campaigns (9.4%) compared to index client trailing (6.0%) and door-to-door testing (5.9%) (P=0.019).
**Conclusions:** Using an innovative combination HTC approach in a high HIV prevalence setting, a large number of adolescents were counselled with very high HIV testing uptake, and high yields of positive tests were found amongst late adolescent girls in particular and at testing campaigns. Expansion of innovative methods to diagnose HIV-infected adolescents in sub-Saharan Africa is required to achieve the UNAIDS target of 90% of HIV-infected adolescents knowing their HIV status by 2020.

## TUPEE563

### COMMUNITY-BASED HIV TESTING FOR ADOLESCENT SEXUAL AND REPRODUCTIVE HEALTH: RESULTS FROM A MOBILE CLINIC INITIATIVE

E. Rousseau-Jemwa, P. Smith, D. Zakariya, L.-G. Bekker
*Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa*
*Presenting author email: dottyjef@gmail.com*

**Background:** HIV testing is sub-optimal in South African adolescents, a population where HIV related deaths continue to rise despite reductions in pediatric and adult HIV related mortality. Discussions with adolescents highlight the inappropriateness of traditional medical facilities to support youth in time of an evolving epidemic and recommend accessible and youth-friendly HCT services to facilitate earlier HIV testing.
**Description:** The Tutu Teen Truck (TTT) launched in August 2015 as a nurse-led, counselor-supported mobile clinic providing HCT services at convenient times and in accessible spaces for adolescents in limited-resource, high disease burden communities of Cape Town. The clinic attracts adolescent clients spontaneously accessing HIV testing at taxi ranks, township shopping/community centres, sports fields or on the roadside opposite schools. Young people were involved in designing the TTT to optimally provide a youth-friendly, integrated SRH service which is culturally appropriate, respectful and confidential. During the HCT visit adolescents complete a self-reported sexual behaviour risk assessment and tailored health education sessions provided by peer-counselors.
**Lessons learned:** Between August and December 2015, the clinic enrolled 1285 adolescents between 12 and 24 ($\bar{x}$ = 17.5) years of age, with 37% being male and 88% black South African. 45.6% of adolescents had no prior HIV test. HIV was newly diagnosed in 2.7% of adolescents, while prevalence was 3.6%. The average CD4/µl count was 429 in newly diagnosed patients, with 67% of positive patients CD4≤500/µl. Adolescents› most prominent self-reported HIV-related risks were that 63% did not know their partner›s HIV status and 52% inconsistently use condoms; while 14.6% had multiple sexual partners in the past six months and 3% were diagnosed with a STI in this same period.
**Conclusions/Next steps:** Mobile, community-based SRH services for adolescents are feasible, while providing an accessible debut HIV testing site for 1 in 2 young people. Although the TTT found a relatively low HIV prevalence by South African standards, the majority of those testing positive qualified for ART. In addition, adolescents accessing the clinic displayed some risky HIV-related behaviour which suggests that PrEP availability could be a valuable. Next steps might be to provide both PrEP and ART for adolescents from mobile clinics.

## TUPEE564

### INCREASING UPTAKE OF HIV, STI AND FAMILY PLANNING SERVICES, AND REDUCING HIV-RELATED RISK AMONG YOUNG PEOPLE LIVING WITH HIV (YPLHIV) IN UGANDA: EVIDENCE OF THE LINK UP PROJECT

L. Vu[1], B. Zieman[1], C. Banura[2], J. Okal[3], M. Elang[4], R. Ampwera[4], G. Caswell[5], D. Amanyire[6], J. Alesi[7], E. Yam[1], Link Up Project
*[1]Population Council, HIV and AIDS Program, Washington, United States, [2]Makerere University, Child Health and Development Center, Kampala, Uganda, [3]Population Council, HIV and AIDS Program, Nairobi, Kenya, [4]Community Health Alliance, Uganda (CHAU), Kampala, Uganda, [5]International AIDS Alliance, Cape Town, South Africa, [6]Marie Stopes Uganda, Kampala, Uganda, [7]Uganda Network of People Living with HIV and AIDS, Kampala, Uganda*
*Presenting author email: lvu@popcouncil.org*

**Background:** In Uganda, youth aged 15-24 comprise nearly 40% of people living with HIV (PLHIV), and new HIV infections continue to rise in this group. As they transition into adulthood, YPLHIV confront unique challenges: stigma surrounding their developing sexuality, and HIV care paradigms which focus on the needs of only children or adults. To address barriers to care, the Link Up project implemented a peer-led intervention through YPLHIV support groups, offering a range of services, including counseling on HIV and sexual and reproductive health (SRH) issues, integrated HIV and SRH education, and referrals to ART and youth-oriented SRH facilities. This abstract presents the evaluation findings of this project.
**Methods:** At baseline (Oct, 2014), we recruited 473 YPLHIV aged 15-24 years who were members of Link Up peer-support groups in Luweero and Nakasongola districts to participate in a cohort study. After a 9-month intervention period (January-September, 2015), we successfully re-interviewed 350 participants. Key outcomes included self-efficacy for condom and contraceptive use (10-item index; dichotomized high/low), comprehensive HIV knowledge (five-item UNAIDS scale), condom use (last sex), HIV-status disclosure, ART uptake and adherence, STI uptake, and contraceptive prevalence. Multivariate logistic regression analysis applied to longitudinal data was used to assess changes in key outcomes from baseline to endline, controlling for gender, age, education, marital status, and number of children.
**Results:** At baseline, nearly 70% of participants were female; 21% married/cohabitating; 77% ever had sex; 23% disclosed HIV status to a sex partner; and 68% were using ART. At endline, 94% attended Link Up peer-support groups; 86% contacted by peer-educators; and 48% received referrals.
Multivariate analyses showed significant increases at endline, compared to baseline, in: self-efficacy [AOR:1.8(1.3-2.6)]; comprehensive HIV knowledge [AOR:1.8(1.3-2.6)]; HIV disclosure [AOR:1.6(1.01-2.6)]; condom use at last sex [AOR:1.7(1.2-2.5)]; STI uptake [AOR:2.1(1.5-2.9)]; ART uptake [AOR:2.5(1.6-4.0)]; ART adherence [AOR:2.5(1.3-4.9]; CD4 testing [AOR:2.4(1.5-3.6]; and use of modern contraceptives: [AOR:1.7(1.1-2.7)].
**Conclusions:** Link Up's peer led intervention through peer-support groups and referrals can be effective in increasing self-efficacy and knowledge of HIV, condom use, HIV disclosure, uptake of ART, ART adherence, CD4 testing, STI uptake, and use of modern contraceptives. This model should be shared and adapted to other contexts.

## TUPEE565

### PHYSICAL HEALTH AND SEXUAL REPRODUCTIVE HEALTH STATUS OF YOUNG PEOPLE IN THE BORSTAL TRAINING INSTITUTION, ILORIN, KWARA STATE, NIGERIA

O. Omole[1,2], A. Sangowawa[3]
*[1]University of Ibadan, Institute of Child Health, Ibadan, Nigeria, [2]Society for Family Health, Measurement and Evaluation, Ibadan, Nigeria, [3]University of Ibadan, Ibadan, Nigeria*
*Presenting author email: opeyemmy2@yahoo.com*

**Background:** Young people (10-24 years) comprise about a third of Nigeria's population. Some of the young people initiate objectionable deviant behaviours and are subsequently remanded in Borstal Training Institutions (BTI) for rehabilitation after trial and prosecution. However, studies conducted in Nigeria among delinquent young people in BTI have not adequately explored their sexual reproductive health status. This research was therefore conducted to assess the sexual reproductive health and determine the physical health status of delinquent young people being rehabilitated in the BTI, Ilorin.
**Methods:** A cross-sectional survey of the 133 inmates remanded in the BTI was conducted. The institution caters for only male offenders who are sentenced by the court of law for an initial period of three years. A semi-structured questionnaire was utilized to collect information socio-demographic characteristics and history of common health symptoms experienced three months preceding the study. Also, Knowledge, Attitude and Practice regarding HIV were evaluated.
**Results:** Data were analysed using descriptive statistics, Chi-square and Spearman rank correlation at p = 0.05. The mean age of inmates was 18.9±2.2 years. Various offences included abuse of psychoactive substances (65.5%), armed robbery (39.8%), "being beyond parental control" (6.0%) and recurrent involvement in street fights (0.8%) led to been remanded. The mean duration of stay in the institution was 1.3±0.8 years. About 57.9% reported that they had at least one symptom such as catarrh (46.8%), fever (42.9%), headache (40.3%), body pain (40.3%), and chest pain (23.4%). Eighty-nine of the Inmates were aware that HIV can be transmitted by sexual intercourse (66.9%).
Half of them knew HIV can be transmitted from mother to child (52.6%) and through sharing needles or syringes (51.1%). About 60.3% of the inmates had misconception about transmission of HIV. Fifty (37.5%) of the inmates had a history of sexual intercourse, and 60% of these inmates had used a condom. However, only 44.0% said they used condoms consistently.
**Conclusions:** It was observed that Inmates of the Borstal Training Institution experienced poor physical health and had misconception about the route of transmission of HIV. There is need for Intervention to improve Inmates KAP on HIV.

## TUPEE566

### UPTAKE OF PREVENTION OF MOTHER TO CHILD TRANSMISSION (PMTCT) SERVICES BY ADOLESCENTS AND YOUNG WOMEN COMPARED TO OLDER WOMEN: EVIDENCE FROM A RETROSPECTIVE COHORT IN SIX SUB-SAHARAN AFRICAN COUNTRIES

N. Kayuni Chihana, S. Chapman, S. Sandfolo, E. Scheepers, K. Schmitz
*mothers2mothers, Department of Programs and Technical Support, Cape Town, South Africa*
*Presenting author email: ndoliwe.kayuni@m2m.org*

**Background:** In Sub-Saharan Africa, young women (aged 15-24 years) are at higher risk of acquiring HIV with sources indicating that their risk is more than twice that of young men. Mother-to-Child Transmission (MTCT) accounts for over 90% of new HIV infections in children. mothers2mothers employ, Mentor Mothers, who are themselves mothers living with HIV, to provide health education and psychosocial support to other HIV-positive mothers in selected health facilities. We used longitudinal client records to compare uptake of PMTCT services and MTCT amongst adolescent women (15-19 years), young women (20-24 years) and older women (25 years or older).
**Methods:** We documented uptake of PMTCT services for HIV positive mothers who presented between June and November 2012 and followed them up for up to 31 months in Kenya, Lesotho, Malawi, South Africa, Swaziland and Uganda. We extracted records of 12,900 HIV positive mothers at a representative sample of 87 health facilities. Using routine M&E data, we used logistic regression to explore PMTCT service uptake and MTCT rates and adjusted for facility type, site location (rural/urban), disclosure status and male partner HIV status.
**Results:** A total of 846 (6.6%) were adolescent women (15-19 years) and 3,465 (26.9%) were young women (20-24 years). Adolescent women (OR=0.70; 95% CI=0.56, 0.87) and young women (OR=0.77; 95% CI = 0.66, 0.91) were less likely to take up postnatal prophylaxis compared to older women. Mother-to-child transmission was higher in young women who were more likely to have an HIV-positive infant compared to older women (OR=1.34; 95% CI = 1.03, 1.77). Other services that adolescent women were less likely to take up compared to older women were infant cotrimoxazole prophylactic treatment (OR=0.77; 95% CI = 0.63, 0.95), Polymerase Chain Reaction (PCR) test (OR=0.77; 95% CI = 0.63, 0.94) and PCR test result (OR=0.80; 95% CI = 0.66, 0.97).
**Conclusions:** Higher MTCT may be partially explained by lower uptake of postnatal prophylaxis amongst young women compared to older women. Lower uptake of PMTCT services by adolescent- and young women emphasizes the need for programmes to specifically target this population segment through social and behavior change, and provision of youth friendly health services.

## TUPEE567

### HOW DO SAFER SEX INTENTIONS IMPACT HIV SEXUAL RISK BEHAVIOR IN YOUNG BLACK MEN WHO HAVE SEX WITH MEN? A MEDIATION ANALYSIS

S.K. Choi[1], S. LeGrand[2], K. Muessig[1], K. Soni[3], H. Kirschke-Schwartz[3], L. Hightow-Weidman[3]
*[1]University of North Carolina at Chapel Hill, Department of Health Behavior, Chapel Hill, United States, [2]Duke University, Center for Health Policy and Inequalities Research Duke Global Health Institute, Durham, United States, [3]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States*
*Presenting author email: seulchoi@live.unc.edu*

**Background:** HIV prevention interventions that reduce sexual risk behaviors among YBMSM, the most severely affected population in the United States, are critical for reducing disparities in HIV infection. The Institute of Medicine (IOM) Integrated

Model of Behavior Change was used as the theoretical basis for development of healthMpowerment.org (HMP), a mobile-phone-optimized, Internet-based intervention designed to reduce unprotected anal intercourse (UAI) among YBMSM. The model theorizes that behavioral intentions mediate the relationship between self-efficacy, perceived norms and attitudes and health behavior. This study used baseline data from 474 HMP randomized controlled trial (RCT) participants to test this model.
**Methods:** Bivariate analyses examined relationships between UAI in the last 3 months and safer sex intentions (intentions to discuss condom use, use condoms, ask sexual partners about HIV status, use alcohol/drugs before sex), self-efficacy to refuse sexual acts, condom use norms and attitudes toward condom use. Mediation analyses were conducted using the SAS PROCESS computational macro to determine if safer sex intentions mediated the relationship between self-efficacy, perceived norms, attitudes and UAI.
**Results:** The mean age was 24.3 years; 39.5% were HIV-positive. Overall 66.1% reported one or more acts of UAI with a male partner in last 3 months. Those who reported UAI had lower safer sex intentions (*p< .001*), lower self-efficacy to refuse sexual acts (*p=.014*), lower perceived condom use norms (*p< .001*) and poorer attitudes towards condom use (*p< .001*). In mediation analyses, the relationships between UAI and self-efficacy to refuse sexual acts (estimated indirect effect=-.02, *p< .001*) and perceived condom use norms (-.04, *p< .001*) were fully mediated by safer sex intentions while attitudes toward condom use (-.02, *p< .001*) was partially mediated by safer sex intentions when controlling for age, education, income and HIV status.
**Conclusions:** The findings from this study supported behavioral intentions as a mediator between self-efficacy, norms, and attitudes and health behavior (e.g., UAI) outlined in the IOM Integrated Model of Behavior Change. These factors are important direct and indirect predictors of UAI among YBMSM. Theoretically-based interventions are critically needed to address these predictors in order to reduce UAI among YBMSM.

## TUPEE568

### LEARNERS' PERSPECTIVES ON THE PROVISION OF CONDOMS IN SOUTH AFRICAN PUBLIC SCHOOLS

W.E. de Bruin[1,2], S. Panday-Soobrayan[1]
*[1]UNICEF South Africa, Education, Pretoria, South Africa, [2]VU University, Health and Life Sciences, Amsterdam, Netherlands*
*Presenting author email: spanday@unicef.org*

**Background:** Despite the introduction of sexuality education in South African (SA) schools 16 years ago, progress has been slow in reducing sexual risk behaviour. In 2015, the Department of Basic Education proposed the provision of condoms and sexual and reproductive health (SRH) services to learners in schools. As the sexuality of adolescents is contested much public debate has ensued, which is seldom informed by adolescents as the beneficiaries of the policy. This study explored learners' perspectives on the provision of SRH-services in SA schools.
**Methods:** Sixteen focus group discussions were conducted with 116 learners (52% female) from 33 public schools across the nine provinces. School selection was based on participation in UNICEF's youth development programmes. The discussions focused on learners' attitudes, social influences and how SRH-services should be provided in schools. Discussions were thematically analysed.
**Results:** Learners reported negative attitudes towards sexuality education because of an uncomfortable interaction with teachers and peers, and a lack of comprehensive information. While some learners had a positive attitude towards the provision of condoms in schools, due to amongst others judgemental attitudes of nurses at clinics, many were concerned that it would increase sexual activity. However, as the discussion ensued on the poor quality of services in clinics and high risk behaviour amongst adolescents, some learners shifted their position. Attitudes towards the provision of other SRH-services in school were positive as learners emphasized that current clinics are not youth friendly. Learners' perspectives on providing SRH-services in schools were strongly determined by the opinions of classmates and teachers. Hence, the most immediate concerns for implementation revolved around ensuring privacy and confidentiality.
**Conclusions:** Learners did not fully support the provision of condoms in schools due to myths about increased sexual activity and fear of stigma and discrimination. The provision of condoms in schools must be preceded by an evidence-informed advocacy campaign that debunks commonly held myths. Critical thinking skills must also be developed to inculcate evidence-informed decision-making on contested issues such as condom provision. Provision must be sensitive to the privacy and confidentiality of learners in light of the persistent stigma and discrimination they experience.

### YOUNG WOMEN'S EXPERIENCE OF RECEIVING CONDITIONAL CASH TRANSFERS FOR HIV PREVENTION: QUALITATIVE DATA FROM HPTN 068

C. MacPhail[1,2,3], N. Khoza[2], R. Twine[3], A. Selin[4], X. Gómez-Olivé[3], R. Wagner[3], S. DeLong[5], K. Kahn[3,6,7], A. Pettifor[2,3,5]
*[1]University of New England, School of Health, Armidale, Australia, [2]Wits Reproductive Health and HIV Institute, University of the Witwaterstrand, Johannesburg, South Africa, [3]University of the Witwatersrand, MRC/Wits Rural Public Health and Transitions Unit, School of Public Health, Johannesburg, South Africa, [4]University of North Carolina, Carolina Population Center, Chapel Hill, United States, [5]University of North Carolina, Department of Epidemiology, Chapel Hill, United States, [6]Umea Centre for Global Health Research, Umea, Sweden, [7]Indepth Network, Accra, Ghana*
*Presenting author email: cmacphai@une.edu.au*

**Background:** There is increasing interest in studying the use of cash transfers with adolescent women in sub-Saharan Africa. Cash transfers are hypothesized to prevent HIV infection by increasing school attendance or reducing young women's reliance on transactional sex. In this study we examined young women's school attendance and unintended changes to social relationships when receiving a conditional cash transfer (CCT).
**Methods:** HPTN 068 was a 3-year randomized controlled trial to assess the impact of a cash transfer, conditioned on school attendance, on young rural South African women's HIV incidence. 2328 13-20 year old women were recruited and completed annual survey assessments. A sub-sample of 71 women (38 from intervention arm) was recruited into a longitudinal qualitative cohort, in which they were interviewed up to twice annually by female, local language-speaking fieldworkers. Interviews were recorded, translated and transcribed for coding and analysis in Atlas.ti.
**Results:** Qualitative interviews with a sub-sample of intervention-arm participants found that receiving the CCT was a largely positive experience. Moreover, the CCT did not negatively impact on relationships in communities, neighbourhoods and schools; which remained essentially unchanged throughout the study. Minor reports of jealousy and teasing within peer groups were reported but they had limited impact on participants. Within families, young women highlighted their increased independence, better relationships with mothers and sharing of resources with siblings. Impact of the CCT on sexual relationships was little and it was rarely mentioned. Quantitatively, we found no significant impact of the CCT on school attendance, however, qualitative interviews show that participants reported positive change in their attitude towards schooling across both study arms.
**Conclusions:** Receiving a CCT was a positive experience for young women and their social relationships were either unaffected or positively changed. Confirming findings from the quantitative trial results, there was no identified impact of the cash on schooling. Notably, fears of negative unintended consequences to cash payments appear unfounded.

## TUPEE570

### PARTNERING TO IMPROVE EMERGENCY AND CRITICAL CARE SERVICES FOR PEDIATRIC HIV PATIENTS IN ETHIOPIA

T. Bacha[1], M. Tefera[1], M. Temsegen[1], S. Butteris[2], S. Hagen[2], J. Ross[2], J. Svenson[2], J. Conway[2], N. Musa[3], Y. Ouellette[4], D. Siraj[5], H. Busse[2], G. Tefera[2]
*[1]Addis Ababa University, Tikur Anbessa Specialized Hospital, Pediatric Emergency Department, Addis Ababa, Ethiopia, [2]University of Wisconsin-Madison, School of Medicine & Public Health, Madison, United States, [3]University of Washington, Department of Pediatrics, Seattle, United States, [4]Mayo Clinic, Department of Pediatrics, Rochester, United States, [5]East Caroline University, Brody School of Medicine, Division of Infectious Diseases, Greenville, United States*
*Presenting author email: tigistbacha@yahoo.com*

**Background:** At the request of the Federal Ministry of Health, the American International Health Alliance launched a partnership between the University of Wisconsin in the United States and Addis Ababa University to strengthen pediatric emergency care in 2010. With support from the President's Emergency Plan for AIDS Relief and CDC/Ethiopia, partners established a fellowship in pediatric emergency and critical care medicine and implemented several quality improvement projects to increase the number of children tested for HIV, ensure early administration of post-exposure prophylaxis, and enhance linkages between the pediatric emergency department and the facility's HIV clinic.
**Description:** Since January 2014, more than 400 pediatric patients have been screened for HIV in the Emergency Department. Approximately 10% tested HIV-positive and were referred to the HIV clinic. In the pediatric intensive care unit, 166 (35%) admissions were screened for HIV; 13 (8%) tested HIV-positive. These rates are significantly higher than the HIV prevalence nationwide (1.2%) and in Addis Ababa (5.2%).

**Lessons learned:** Children may not come into regular contact with the healthcare system and may not utilize services unless they are injured or severely ill. Emergency and critical care providers are therefore uniquely positioned to identify and diagnose new pediatric HIV cases during emergency situations and refer positive cases for immediate care and treatment. Emergency settings should be seen as important catchment areas for children living with HIV, who may otherwise remain undiagnosed and untreated.
**Conclusions/Next steps:** HIV testing and referral services are a critical component of pediatric emergency and critical care. Additional data collection is needed to quantify the impact of providing specialized emergency care for pediatric patients in high HIV burden areas.

## TUPEE571

### ADDRESSING INTERGENERATIONAL COMMUNICATION IS KEY TO DEVELOPING AN "ADOLESCENT-FRIENDLY" FAMILY-BASED HIV TESTING INTERVENTION

N. Gillespie[1], L. Knight[2], Z. Essack[1], N. Ngcobo[1], T. Rochat[1], H. van Rooyen[1]
*[1]Human Sciences Research Council, Human and Social Development Programme, Pietermaritzburg, South Africa, [2]University of the Western Cape, School of Public Health, Cape Town, South Africa*
*Presenting author email: ngillespie@hsrc.ac.za*

**Background:** Adolescents occupy a unique position in the family as they make a transition from childhood to adulthood. During this phase, adolescents may engage in risky behaviour that their families are unaware of. As a result, adolescents may be reluctant to participate in family-based interventions that could expose their private lives. A key consideration in developing an "adolescent friendly" family-based intervention is supporting intergenerational communication to encourage adolescent-parent sharing while simultaneously supporting the adolescent's need to develop their own identity and gain a sense of autonomy.
**Methods:** In 2014, 72 adolescents in KwaZulu-Natal, South Africa, participated in the formative phase of a research study to develop a family-based model of home-based HIV counselling and testing (FBCT). Participants were identified through social networks, schools and community groups. Qualitative data was collected using mixed-gender focus group discussions. Participants were stratified according to age (13-14/15-16/17-18 years) and HIV serostatus (HIV positive/HIV negative/HIV serostatus unknown). The data was analysed using a thematic analysis to assess differences across age groups and to identify factors that would facilitate or hinder adolescent participation in an FBCT intervention.
**Results:** Adolescents across age groups reported openness to communication with parents, but communication waned as adolescents grew up. Younger adolescents reported fear of parental disownment as a key barrier. Whereas, middle adolescents cited difficulty in initiating conversations with parents. In contrast, older adolescents appeared to be able to initiate conversations using tools such as humour but found straight-forward communication with parents difficult. Across age groups, parents making time to speak with adolescents was an important communication facilitator. Younger adolescents preferred parent-initiated communication. While older adolescents reported that certainty of parental care and support motivated adolescent sharing. Adolescents across age groups felt more comfortable communicating with a female caregiver as opposed to a male caregiver. However, younger adolescents expressed a desire for fathers to be more involved and available for communication.
